As a former teacher in law school, I remember starting off my classes by saying to some of my students, "Don't use the word justice in this class. You can talk about the law, but we will leave justice for the philosophers and theologians. We have to deal with something else here, and the cumulative effect of the system results in justice if it actually occurs."

That is the problem.

As Mr. Roisman said, there are people who have won cases who shouldn't have, and there are people who lost cases that shouldn't have. All we can do is fashion a system with its rules and procedures and rules of evidence that overall achieves justice in a broader sense.

Thank you very much, Mr. Roisman, for your extremely helpful testimony. We appreciate your contribution and particularly coming from your viewpoint as a former member of the Justice Department dealing with these matters.

You have made a significant contribution to our proceedings. Thank you.

Mr. **Roisman**. Thank you.

Mr. **Levitas**. The next panel of witnesses is a group I have been looking forward to hearing from for quite some time now, because we move closer to the nub of the problem on the subject of toxic torts or the tort system and compensation which is a part of this phase of our inquiry.

So I would ask the panel of Mr. Lundquist, Mr. Light, and Mr. Baron, if they would come forward and raise your right hands.

[Witnesses sworn.]

Mr. **Levitas**. In passing the Superfund law in 1980, section 301(e) provided in subsection 1 the following, "in order to determine the adequacy of existing common law and statutory remedies in providing legal redress for harm to man and the environment caused by release of hazardous substances into the environment, there shall be submitted to the Congress a study within 12 months of enactment of this Act"—and it goes on to describe the study and what it is attempting to achieve.

That study has been prepared and there is still remaining controversy about it. It is for that reason, as we approach the whole question of compensation through the legal system and the toxic tort area, the victims compensation, that the testimony of these three witnesses is extremely pertinent.

Mr. Albosta, I know for a fact some of the questions you were just raising, and Dr. Rowland was just raising, will be addressed by these witnesses in the course of their testimony.

So, we welcome you gentlemen. We appreciate your being here and we look forward to what you have to say.

Mr. Lundquist, why don't we begin with you?

TESTIMONY OF WEYMAN I. LUNDQUIST, ESQ., HELLER, EHRMAN, WHITE & McAULIFFE, SAN FRANCISCO, CA; ALFRED R. LIGHT, ESQ., HUNTON & WILLIAMS, RICHMOND, VA; FREDERICK M. BARON, ESQ., FREDERICK M. BARON & ASSOCIATES, DALLAS, TX

Mr. **Lundquist.** I am from San Francisco, I am Weyman Lundquist, I am a trial lawyer by profession.

I say trial lawyer in that I mean I spend a good bit of my time in the court. I represent individuals in contingent fee cases, I represent corporations in the defense of their interests, I have had some experience many years ago in representing the Government as an Assistant U.S. Attorney.

I think it may be helpful to this group to give you a little background both as to how I came to be on the Superfund Committee, and the Superfund Committee makeup itself.

I came on as a member of the American Bar Association. There were four groups to be involved, American Trial Lawyers, American Bar Association, the American Law Institute, and the Association of Attorney Generals.

The reasoning underlying the makeup of that committee was to give both balance to the views and also a diversity of experience.

Within the ABA, I believe my reason for being here is that I have had a long interest in environmental matters, I have been involved with them, I have had some direct involvement in the courtroom, but much of it in study and in related activities of a public nature.

I also have, over the years, worked a good bit with study of the tort system. I serve on the ABA committee with Griffin Bell, which is studying the tort system. I have had much to do with procedural matters within the courts of the United States, particularly Federal, in terms of civil procedure revisions that have been undertaken there.

Now, more directly to the Superfund and what we have come up with, to all person's views is derived from their own experience. I think one of the reasons for the need for Superfund Inquiry Fund Recommendations and why this group came up with them is that we are basically facing a new type of problem with toxic injuries. Let me explain.

We know today more and more why people die, as people continue to live longer and longer. We get over a point at World War II and where most people were dying for biological or natural causes, where the human longevity was in the area of 50 to 60, years Following World War II with increased health care, sanitation and otherwise, people lived longer and longer.

Generally, as you become injured at an older age or sick at an older age, there is less compensation available and, indeed, lawyers are less interested in representing you simply because your case is not worth as much money.

A further paradox to this is that the older people very often are older because of the very things that will bring about their demise. Specifically, my father is 78 years old. Since he emigrated from Sweden, he has spent his employment life in a factory in the United States making grinding wheels.

Now, my father's longevity has already far exceeded what he could have expected at the time of his birth. I would say that it is very probable if an autopsy is performed at his death that you will find that the cause of his death will probably have something to do with his working in an abrasive factory. At the same time, that very work has enabled him to live a long and full life.

That is a paradox.

The other aspect of this is that there is no question that some people are severely affected by toxics and die early of diseases such as cancer. Indeed I can remember in that same factory where my dad worked, some people only had one lung because that was happening.

You can't ignore these people. So we are faced with a need for balance. Our system is in essence faced with trying to balance these two problems.

We have had further problems, some on the medical side already alluded to. Some on the business side which is, of course, interested in profitability, with generally short-term motivation.

There are some on the legal side. Lawyers have vested interests which they seek to defend, both defense lawyers and plaintiff's lawyers. So all of these things were to some extent tensions and yet, accommodations which have to be worked out in the Superfund, personal injury recommendations.

As I now view it, I think it is a relatively satisfactory proposal.

What the recommendation does in essence is provide for people who are generally not now, in my judgment, well provided for. These are the cases that would come into it. These are the cases which lawyers advise be brought into it—who don't have distinct, obvious, easy-to-prove injuries. Nonetheless, they have medical bills, they have concerns, they have some disability.

In my judgment, most of them, probably will be older because when you get to mass groups, these are latent problems and age enters into it. If you get the younger person already alluded to, generally that person doesn't have difficulty finding a lawyer who will undertake to present that case on a contingent-fee basis and if it is at all good probably will prevail with it.

It is worth the effort.

But for the larger, older group, it is not. So, our Superfund group proposed that in more limited damages and with easier proof, you could come into the Superfund compensation system.

One of the things——

Mr. LEVITAS. Let me interrupt you there, when you say Superfund, are you talking about the Superfund Committee?

Mr. Lundquist. I am talking about our recommended proposal, yes. I should have been more precise.

Mr. Levitas. I just didn't want the record to be confused when it is read subsequently. The present Superfund law does not provide for what you are talking about, but the proposals of the 301(e) committee do.

Mr. Lundquist. Yes, I appreciate that. The context of my remarks is all in that direction. I am not speaking about Superfund other than in the context of the recommendations of our committee.

Our proposal, Tier 1, as we came to call it, was basically an administrative system administered by the States which might give people not the full expanse of compensation they might seek in some courts—certainly in the courts of California—but more limited, specific, and one would hope expeditious receipt of benefits.

It also, I think, did something else which was important, it created presumptions in connection, that is it made it easier for the person who could show that they were engaged in an occupation or suffered exposure from a hazardous substance, to establish they had an injury or disease which was known to derive from that exposure which have created a presumption of injury entitling them to compensation.

The process was further eased by providing that you could develop toxic substance documents. These would be scientifically established, governmental based documents, which would make the nature of the proof easier. One wouldn't have to go out and show that an individual suffered causation in this way. It was a way of minimizing scientific problems and giving a more generalized overview approach.

The interesting thing about the presumptions is that on the defense side, they are essentially not liked in some respects, because it would make it easier to prove a case. To my surprise, they were also resisted by people at the plaintiff's bar of the regular tort system because they said their view is that these make it a minimum standard, and a court would say: If you don't have that presumptive case, you won't have a case in our court.

I, myself, when I am a plaintiff, would rather have the benefit of presumptions, but the plaintiff's bar took the view that that was not the case.

This shows that presumption can be helpful in the level and type of case we are talking about with Tier 1.

Tier 2 doesn't use presumptions. It uses the traditional court system. I think it should be said that our court system has generally functioned well. People don't always like it, but it has been useful in causing evolving law, indeed, the law that we speak of today is entirely different from the law we knew a decade and certainly two or three decades ago.

We need to keep that evolving part of it, too. I am a firm believer in a system which utilizes juries, because I think juries make social judgments. They must understand and apply the law. In a democracy, laws are an essential part of it.

So, I think it is necessary that that part of the system remain there.

Finally, two points, because I don't want to run on unduly.

Mr. **Levitas**. Let me say this, your entire testimony, Mr. Lundquist, and that of your colleagues, will be made a part of the record, without objection. But you may proceed.

Mr. **Lundquist**. I understand that. I didn't know it was going to be part of the record until Friday morning, so I apologize for its brevity because I think there is more to be said.

That was one of my two final points.

The last point that I want to make, and it is the one to me that is the most important, I think victims should be compensated, I think it has to be done, and it has to be practical and effective.

One of the problems about the toxic type of claim is that it is clogging the system. It is taking far too long to get through the system. This claim is aberrational because you get the people who are responsible fighting among themselves, be they insurance companies saying: "We didn't have the coverage," or "It isn't there," or companies saying, "It is not our problem." This makes it aberrational in the sense that most claims that we would face in life are settled not in court, not even at the lawsuit level of court, 98 percent of claims are settled at the claims level when somebody goes to a company or an insurance company and it stays out of the judicial system.

We get, once into the judicial system, 98 percent of the cases settled after the 1 to 2 percent which enter the system. We have aberrational problems here where the nature of these claims, involving latent defects, means that you can't find responsible people. These cause delay and expense and slow the process.

For that reason, I think we do need a different sort of solution. I have more information, as we see Minnesota has just passed a law recognizing this. Before long we will have better information as to how it works.

But the other thing we must consider in all of this is that compensation essentially reflects a short-term approach. Each and every one of us is a steward of our children's futures and as I noted in my conclusion to the study group report in a few paragraphs which I will now read, which express my own views:

"The significant lessons learned from our work is that further emphasis, economic, legislative, legal, should focus on avoiding toxic injury problems. Today and tomorrow's efforts and legislation should concentrate on having generators of hazardous waste develop ways to make them benign. Emphasis should be on the treatment of waste materials to make them safe.

While I favor compensation, I urge that the legislative efforts be pursued and incentives be given to those who will solve the problems which we might otherwise perceive 20 years down the road.

Thank you.

[The statement of Mr. Lundquist follows:]

TESTIMONY OF WEYMAN I. LUNDQUIST BEFORE THE SUBCOMMITTEE ON INVESTIGATIONS AND OVERSIGHT OF THE COMMITTEE ON PUBLIC WORKS AND TRANSPORTATION

JULY 26, 1983

I am pleased to be here. My name is Weyman Lundquist. I live in San Francisco, California. I want to emphasize at the outset that my remarks express personal views. I do not speak for any client or organization with which I am associated.

Mine is a longstanding interest in environmental concerns. I have handled environmental litigation and have been directly involved in environmental activities in Massachussets, Alaska, and California. More significantly, I have been associated with a number of organizations generally recognized as having environmental concerns, including California Tomorrow, The Natural Resources Defense Council, The League To Save Lake Tahoe, and the Sierra Club. Again I speak for none of these organizations today.

With those general remarks let me turn to the matters that I have been asked to address here. I have been asked to comment on the following subjects: the reason for the establishment of the 301(e) Study Group under the Comprehensive Environmental Response, Compensation and Liability Act of 1980; the nature of the Study Group's membership; the Study Group's recommendations; and the compromises that were necessary to achieve these recommendations. In addition, I will present my own views about the need for a special legislative emphasis on the prevention of ongoing toxic problems.

REASONS FOR ESTABLISHING THE 301(e) STUDY GROUP

The Comprehensive Environmental Response, Compensation and Liability Act Of 1980 (CERCLA)[1] created what is now known as Superfund. Superfund is a trust fund that is designed to finance the cleanup of hazardous waste sites and toxic spills. CERCLA, however, does not provide for the compensation of personal injury or property damages that result from the exposure to hazardous wastes. Instead, in Section 301(e) of CERCLA, Congress authorized the creation of a Study Group to evaluate the problem of compensating personal injury and property losses associated with hazardous wastes.

The Study Group's statutory mandate literally authorizes it "to determine the adequacy of existing common law and statutory remedies in providing legal redress for harm to man and environment caused by the release of hazardous substances into the environment. . . ."[2] The Study Group was authorized to examine the nature, adequacy, and availability of existing remedies to compensate for these harms and the barriers to recovery for such harms within the current legal system. The Study Group was also asked to submit appropriate recommendations to Congress regarding the need for revisions in statutory and common law so that such personal injury and property damage would be adequately compensated for.

---

[1] Comprehensive Environmental Response, Compensation And Liability Act of 1980, Pub. L. 96-510, Section 301(e), 94 Stat. 2767 (1980).

[2] *Id*. § 301(e), 94 Stat. 2807.

I should point out that the Study Group's explicit statutory authorization asks it to study injury and damage resulting from "the release of hazardous substances into the environment."[3] As noted in Frederick R. Anderson's statement following the Study Group's Report, "our mandate directed us to examine recovery for injury from the broad category of hazardous substances, not merely from hazardous wastes."[4] In fact, the first compromise the Study Group made was to narrow the focus of the study by concentrating only on the problem of hazardous wastes. As Mr. Anderson continues in his statement, however, "the proposals discussed herein, and our conclusions about the inadequacy of the common law, both can be generalized to apply to the entire spectrum of common law recoveries for injury from hazardous substances. . . . [T]he framework for analysis and the basic criticisms remain the same."[5] I concur.

THE DIVERSITY OF THE 301(e) STUDY GROUP MEMBERSHIP

For any group to speak with authority concerning legislation, it should be a group representing a spectrum of views and having no particular bias. Ideally, this constituency should include the views of academicians, the government, lawyers who represent individuals, lawyers who represent commercial interests, and appropriate associations. The Study Group was made up of such a membership. Study Group members were appointed by four separate organizations. They were the American Law Institute, the American Bar Association, the American Trial Lawyers Association, and the National Association Of Attorneys General.

It is clear from the composition of the Study Group that Congress did not intend and did not create a group that would reach an easy consensus. The variety of interests that were reflected in the Study Group, however, did not lead to an inconclusive report. The final report reflects substantial agreement by the Study Group members. Although some of the Study Group members submitted separate comments to the report, these comments generally did not dissent from the basic two-tiered remedial proposal. Even the dissenting comments, those of Judge Breitel and those of George Freeman, supported the establishment of an administrative compensation remedy while allowing claimants an opportunity to pursue common law remedies.

It should be noted that some of the committee members - both plaintiffs' lawyers and defense lawyers -- have a vested self-interest in their espoused views. As the discussions of the Group progressed, it became evident that certain other Group members, particularly academicians, sometimes also had a vested interest in views they had expressed over a number of years. Not surprisingly, each constituent group of this committee was conservative in favoring what it knew best. This was as true of the plaintiffs' lawyers as it was of the defense oriented counsel.

THE GROUP'S DELIBERATIONS

The Study Group had no doubt that toxics are a problem. They are a problem because there is some individual harm. They are a problem because of public concern about potential harm. They are a problem because of the latent harm that they may yet create. As they continue to be developed, toxics present an increasing problem in American society. Among the more difficult dilemmas the Group faced, however, was evaluating how immediate the problems are and what solutions might be most expeditious and economic. The Group was also confronted with questions involving bars to recovery and the transactional costs of resolving these problems.

A major conundrum underlay the Group's deliberations: what is the size of the problem? We know without question that large numbers of people have been exposed to toxic risks. The extent of physical detriment suffered by these people is less well known and less well established. Developing medical science increasingly enables us to learn why people become diseased and die. A few short decades ago such determinations would not have been possible. Some who develop diseases may be significantly disabled by them, and in the main more people continue to live longer. Thus, the actual harms caused by toxics are difficult to measure.

Because of the multifactorial etiology of most of the injuries that are related to exposure to toxics, most of the scientific literature is very inconclusive as to injury causation. Disease incidence in populations that have been exposed to a given toxic substance is usually reported either simply as incidence, without any conclusion as to causation, or at best as a correlation. Some of the paucity of the causation conclusions is related to the high burden of proving statistical significance in scientific stuidies. Some is related to the dose-response curve; researchers who are willing to make causal conclusions regarding high exposure levels may be unwilling to make the same conclusions regarding lower exposure levels -- exposure levels that may still be toxic, but for which the incidence of injury is so low that the data necessary to prove causation are not available. Furthermore, for a great number of scientific conclusions regarding toxic substances, whether the conclusions have been in the form of correlations or causal connections, further studies have either failed to replicate the original results or have reached contradictory results. In addition, the synergistic effect of toxics with other harmful substances -- particularly smoking -- makes it difficult to give definitive answers.

Even for those substances where a causal relationship between the toxic substance and an injury is accepted, there is almost a complete absence of data that indicates the age groups affected, which in turn would indicate how many lives are actually being shortened or severely impaired by the injuries that result from exposure to these toxic substances. Both the Love Canal data and the asbestos data suggest that most injuries manifest themselves in older populations. However, substances such as DES and DBCP have been proven conclusively to have severe effects early enough in the lives of the victims so as to seriously disrupt their lives, lifestyles and life expectancies.

Since the Supreme Court's Benzene[6] decision, administrative agencies have not been able to regulate exposure to toxic substances unless there is sufficient data to prove that there is a "siginificant" risk of harm from these substances. Thus various substances that may be toxic cannot be regulated at the present time because of insufficient scientific evidence of harm, or because of insufficient scientific data regarding the toxicity of these substances at low exposure levels. Because of the long latency period between exposure to toxics and the resultant injuries, it is thus possible, and in fact likely, that mass toxic tort injuries caused by these substances will manifest themselves in the future. As Judge Breitel noted in his separate comment to the Study Group report, "[t]here are toxic substances and wastes which were, on any test, deemed not harmful and even beneficial at one time. And there are substances today, without any determinable responsibility, which appear to be utterly harmless or even beneficial or essential, which later, or tomorrow, will have been discovered to be toxic singly or in synergistic relation with other substances."[7] Indeed, the lack of scientific conclusions as to causation does not indicate that various substances are not toxic or will not cause toxic harms. Rather, the absence of data merely indicates that researchers have not yet been able to prove that particular substances are not safe. The Study Group was thus confronted with the situation where the extent of these harms has not yet been quantified.

---

[6] Industrial Union Dep't, AFL-CIO v. American Petroleum Inst., 448 U.S. 607, 653 (1980) (plurality opinion).

Furthermore, a few short decades ago, people's life spans were substantially shorter. Indeed, one of the ironies of what we face is that the lives of many people will ultimately be adversely affected by toxics and yet their life expectancies have been increased by the very societal developments that were made possible by these substances. Asbestos and pesticides are good examples of this. Thus, we are seeing people who ultimately die or are disabled by exposure to the very substances that have permitted the lifestyle that has extended their lives.

With this background of factual uncertainty, the Study Group focused on some of the problems that confront an injured plaintiff who attempts to seek compensation for a toxic injury. The most significant of these problems are the statute of limitations, joinder of parties, and proof of causation. Because of the long latency period before the manifestation of injury that results from exposure to toxic substances the statute of limitations presents almost a complete bar to recovery in those states that have not accepted a discovery rule. Plaintiffs may lose their right to bring a lawsuit before they have learned of their injuries. Ownership of a hazardous waste site, or of a corporation that produces a toxic substance may have changed during the long latancy period. The questions of liability and apportionment of liability thus become complex. Because of the complexities inherent in toxic tort suits, the costs of pursuing an action become a substantial barrier to a plaintiff's recovery unless joinder of plaintiffs or class action is available. Because of the multifactorial etiology of the injuries most commonly associated with toxic substances -- cancer and lung disease -- proof of causation is extremely difficult. Medical and scientific testimony, used to establish causation, is prohibitively expensive, even in cases in which the etiology of a disease may be rather clear. In the face of such problems, many of the committee members were of the view that the costs of disposing of toxic harm claims were excessive and, indeed, that the victims of toxic harms are frequently compensated less than those who act on their behalf -- their lawyers.

---

[7] 1 Report, supra note 4, at 297 (Comments by Charles D. Breitel).

Further, there is currently no federal statute that expressly provides a remedy for personal injury due to hazardous waste exposure in non-occupational settings and state statutes creating such remedies are rare. Plaintiffs in most situations must rely on common law tort causes of action.

THE COMMITTEE'S RECOMMENDATIONS

Because of the substantial barriers a private plaintiff faces in an action for damages caused by hazardous waste exposure, particularly where the individual claim is small, the Study Group recommended a two-tiered administrative-tort proposal. Zazzali & Grad's review of the Study Group's Report well summarizes the committee's recommendations. I will quote directly from their summary.

> The first step of the proposal, Tier One provides no-fault compensation for personal injury resulting from hazardous waste, to be managed by the several states under a federal program. This compensation plan, operating in a similar manner to workers' compensation, would provide full recovery for a person's medical expenses and, with certain limits, recovery for two-thirds of a person's loss of earnings. Death benefits for close surviving dependents would also be provided. In addition, injured persons would have the choice of proceeding with a personal injury claim under existing tort law, but the amount of any compensation award recovered by the claimant in Tier One must be deducted from, and be paid back out of, any judgment or settlement in a Tier Two plenary action. A person electing to seek compensation under both tiers must repay the Tier One compensation award out of any payment obtained in the personal injury action. A person who recovers under both tiers will also be required to pay certain costs if the Court found that the settlement or award in Tier Two did not substantially exceed the

> compensation award at Tier One. This provision is intended to avoid frivolous claims.8

The administrative compensation plan designed in Tier One would be established by federal legislation, would be operated by the states, and would provide compensation without a showing of fault. It would cover injuries resulting from exposure to hazardous wastes, but excluding occupational exposure covered under the workers compensation system; it would thus be co-extensive with the coverage of CERCLA. To ease the problems with proof of causation, a rebuttable presumption was designed, such that if a plaintiff was exposed to a hazardous waste and suffered an injury that is known to result from exposure to this hazardous waste, the exposure would be presumed to have caused the injury. This presumption would be effective only in the Tier One setting. The compensation awards would be financed by the creation of a fund from industry contributions, analagous to CERCLA's Superfund. This fund would be subsidized by federal contributions or taxes and to some extent would be replenished by the collection of subrogation claims.

The second tier of the two-tier remedial proposal suggests alterations to common law and statutory remedies for hazardous waste exposure. The Study Group recommended the unified adoption by all states of a discovery rule, such that a plaintiff's cause of action would not accrue until the plaintiff discovered or reasonably should have discovered the injury and its cause. The

---

8 Zazzali & Grad, Hazardous Wastes: New Rights and Remedies?, 13 Seton Hall L. Rev. 448, 464 (1983) (footnotes omitted).

Study Group further recommended the adoption of liberal joinder rules, a shifting of the burden of damage apportionment to defendants who contributed to the injury, and the application by the states of a theory of strict liability in toxic exposure cases.

An "exit toll" was designed to minimize frivolous suits and the potentially increased costs that could result from a scheme that allows for dual recovery. Tier One compensation would be deducted from, or paid back out of, any settlement in a Tier Two action. If a Tier Two settlement does not yield compensation that exceeds the Tier One settlement by more than 25%, the judge would have the discretion to assess costs against the plaintiff.

COMPROMISES INCORPORATED IN THE RECOMMENDATIONS

The diversity of the 301(e) Study Group membership necessitated that various interests would have to be reconciled to achieve a compromise recommendation. The Plaintiff's Bar, with its contingent fee interests and its concern for preserving the right to jury trials, was reluctant to endorse any recommendation that would have included a binding election between administrative and tort remedies. The academicians in the Group were more inclined to take a systemic view of the problem, and to be concerned about the forum-clogging, burden on judicial resources, and excessive disposition costs that extended judicial procedures might create. They were thus concerned about the duplication allowed by a scheme that does not require an election of remedies. The Attorneys

General, having a more practical orientation, were more willing to compromise so as to reach a consensus recommendation. In my view, because in current dollar terms the average damage claim for hazardous waste injury is likely to be in the $10,000 to $15,000 range, I am inclined to believe that our Tier One-Tier Two Recommendation is practical; most claims will be handled by the administrative remedy and will not necessitate a tort action in court.

As noted in their separate statements that follow the Study Group Report, a number of the study group members felt that an alternative to the recommended relationship between Tier One and Tier Two remedies would be more advantageous. Under this scheme, an election to obtain the administrative award would be binding, and a plaintiff would need discretionary judicial approval to bring a Tier Two (tort) action. A plaintiff would only be allowed to pursue a tort remedy in the event of an unanticipated cause of action for damages available under tort law beyond that recoverable at the administrative level. Those Study Group members who prefer this binding election between remedies, rather than the exit toll created by the Study Group's recommendations, do so because they find the availability of combined Tier One and Tier Two remedies to be unnecessarily duplicative, inefficacious, and inequitable. Judge Breitel in particular has expressed the view that "[t]he 'exit toll' is not severe enough to avoid 'gambling', that is, obtaining easy recoveries at the administrative level, and then pursuing the plenary action."[9] In my view, if the majority of claims are not large, then they are not likely to be pursued in court -- "the game is not worth the candle." It may be that some restrictions will have to be placed on lawyers amassing numbers of claims to prevent undue economic motivation for lawyers, if not their clients.

Another area of compromise concerned the definitions of causation, presumptions, and discovery of injury. Mr. Freeman in particular, as I am sure he will testify to at length before this Subcommittee, was critical of the statutory presumptions proposed by the Study Group. Both Mr. Freeman and Judge Breitel objected to the use of legislative fiats that reflect policy biases as a substitute for the truth in an area in which the truth is elusive.[10]

Judge Breitel and Mr. Freeman were both particularly concerned that an insufficient cost-benefit analysis had been performed.[11] Both question whether subrogation of claims and taxing of various selected industries are the most appropriate ways to fund such an administrative compensation scheme.[12]
Mr. O'Connell was concerned both that the availability of Tier One,

subrogation, and Tier Two proceedings would place an undue burden on the judicial system,[13] and that the availability of compensation from a Superfund-type trust fund, in addition to payments available under private health insurance, sick leave and disability insurance, would result in a windfall to claimants.[14] A number of the Study Group members were also disconcerted that the Study Group's recommendations did not include awards for psychological, social, and related injuries in the Tier One administrative remedy.

As I stated in my final comments to the Study Group Report,[15] I endorse the Report. I am also comfortable with the Anderson, Breitel, Freeman, O'Connell position (binding election between Tier One and Tier Two with judicial discretion to allow tort actions after an administrative remedy has been elected),[16] and could join this position should Congress deem it advisable.

EFFICIENT USE OF LEGISLATIVE RESOURCES

Having giving the preceeding descriptive, I would like to make some personal observations. As I noted above, we lack good basic information as to the nature and extent of the toxic injury problem. There is no doubt that those who are disabled should be compensated in the most expeditious, efficient manner possible.

---

[13] Id. at 354 (Comments by Jeffrey O'Connell).

[14] Id. at 353 (Comments by Jeffrey O'Connell).

[15] Id. at 349 (Final Comments by Weyman I. Lundquist).

[16] Id. at 286 (Joint Statement of Messrs. Anderson, Breitel, Freeman, & O'Connell).

Every effort should be made, however, to ensure that our concerns in this area do not allow us to overwhelm ourselves with bureaucratic institutions. Indeed, a sunset provision should be included in any compensation scheme that is established; the need for such a program should be reexamined at least every decade.

I am particularly concerned that our current focus on compensating individuals for toxic injuries will blur our ordering of priorities. Our emphasis should be on avoiding toxic injury problems, rather than creating compensation mechanisms for them. As I noted in my individual comments to the Study Group Report:

> The significant lessons learned from this [the Group's work] is that further emphasis -- economic, legislative, legal -- should focus on avoiding toxic injury problems. . . . Today and tomorrow's efforts and legislation should concentrate on having generators of hazardous waste develop ways to make them benign. Emphasis should be on the treatment of waste materials to make them safe. . . (51)
>
> It is not farsighted to justify current industrial activity on the grounds that economic pressures at home or from abroad mandate that we permit today what we can anticipate will be a greater problem tomorrow. . . . It would be nice if one could anticipate that free-market economic forces, left unfettered, would lead to the goals we seek. That has not happened. It is unlikely to happen when short-term gain conflicts with long-term problems and costs. It is difficult to ask that we act now to protect future generations. It is however both wiser and kinder to do this than for us to ask those yet unborn to pay for what we enjoy. . . .
>
> . . . The very need for this committee's study arises from the fact that past unconsidered conduct has given rise to substantial present harm which we must now seek to redress with dollars as the best available substitute for health or damage to property.
>
> Unless we live within the capabilities of our resources and knowledge, we are putting at risk the futures of others. One of the sound tenets of our economic system has been that one saves now to invest for the future, for oneself and others. Unless we adopt this

> prudence in our approach to toxic injury and damage, we run the risk of bankrupting the lives and futures of others.17

We must adopt a more prudent orientation toward toxic substances. I endorse the Study Group's compensation recommendations, however, I would not like to see Congress focus on such a compensation scheme to the exclusion of a focus on preventitive measures.

Finally, we mus be certain that we do not attempt to circumvent the hazardous waste problem by exporting our hazardous wastes. Such an attempt would be both inefficacious and unjust. We should under no circumstances permit the export of products -- and of the problems and injuries concommitant with these products -- which we would not be willing to accept within our own domestic boundaries.

---

17 Id. at 350-52 (Final Comments by Weyman I. Lundquist).

Mr. Levitas. Thank you very much, Mr. Lundquist, for a very pertinent and succinct testimony.

Dr. Light, perhaps we can hear from you at this time. By way of introduction, would you give us a little of your background and so forth?

Mr. Light. I didn't realize they were going to put Dr. Light on the witness list. I am not a medical doctor like Dr. Lawland, I am a Ph.D. in political science and, as an aside, I am a relatively new lawyer. I have been with Hunton & Williams for about 1½ years, and one of the first projects that I was assigned was to be a staff member to George Freeman, Jr., who was a member of the Superfund study group.

Mr. Freeman wishes to apologize to the committee for his not being able to be here personally. A dear friend of his for many years unexpectedly died this past weekend, Angus Macaulay, and Mr. Freeman was responsible for funeral arrangements.

I am here in his stead.

I ought to start off by saying I am not a trial lawyer, and not a hired gun, as my colleagues here. I am really probably as much an academic as I am a hired gun. My own experience in this area has been on a scholarly level as a teacher and political scientist.

I have prepared a summary of my own views on this matter for the National Science Foundation, but the document distributed here is the testimony which Mr. Freeman would have presented had he been here, and I am here basically to summarize that testimony briefly, and answer questions to clarify any aspects of that testimony, which is quite lengthy.

However, to the extent that we go into matters which are not covered in that testimony, Mr. Freeman has volunteered to provide any responses to the questions you might prepare for him, and I will be happy to convey them to him.

I have an assistant here, Mr. Paul Mirengoff, who will be taking notes and trying to keep me honest on that.

Mr. Levitas. We will accept Mr. Freeman's testimony and make it a part of the record, and we regret that circumstances are such that it prevented his participation today.

We welcome the opportunity to present other questions by way of followup to him, and appreciate your participation.

I must say that Mr. Freeman's name rings a bell in my head somewhere, and I am trying to figure out where I know him from.

Mr. Light. Mr. Freeman is a representative of the utility industry on a number of matters and has appeared before various congressional committees.

He is active as Mr. Lundquist is, in the American Bar Association, and I suspect on the basis of your background, that you have seen him in connection with the regulatory reform legislation.

Mr. Levitas. I think so.

Mr. Light. S. 1080, H.R. 2327, and so forth.

Mr. Levitas. OK.

Mr. Light. Our general perspective within Mr. Freeman's office at Hunton & Williams has been from the point of view of administrative lawyers and to a lesser extent corporate lawyers, as opposed to trial lawyers. His own practice has been primarily before administrative bodies such as EPA, NRC, and so forth.

So, he and I are administrative rather than trial lawyers. On some trial issues, you may well find the advice of my colleagues more pertinent than mine.

In general, Mr. Freeman supported the 301(e) approach. There were several matters on which he had some serious disagreements with the majority and felt compelled to outline in a separate statement in the report.

On the whole, this rather weighty document which I brought a copy of, the Superfund 301(e) report, does in my view adequately summarize the present state of the law in this area, and in some related areas.

There are some gaps which in some cases may have been deliberate and in other cases just oversight. But, if you read the report itself, and the separate statements, I think you gentlemen will get a general feel for most of the issues, some of which you have already discussed in previous hearings and so on. The report is a good rehearsal of the congressional debate over this victim compensation legislation.

There were five areas where Mr. Freeman had such serious enough disagreements that he felt he should outline them in his remarks. They were as follows: First, I think it turned out that Fred Baron and Mr. Freeman, at least at the conclusion, tended to be in the same camp on this matter of statutory presumptions.

Mr. Freeman, however, went along with the toxic substance rulemaking idea which Mr. Lundquist outlined. However, he felt that their preparation was an appropriate function for only some Federal agencies. He would not put it in EPA because of its regulatory responsibilities, but might put it in one of the National Institutes of Health or in some other scientific agency divorced of regulatory responsibility.

Nevertheless, he felt that writing statutary presumption into the statute without an adequate factfinding record on a particular substance might lead to a situation that would just be more confusing than the present situation.

That, coupled with what he heard from the plaintiff's bar in connection with the two-edged nature of the thresholds or criteria which might be written into the statutory presumptions, compelled him to dissent on that point.

On another issue, the funding of the fund, analogous to Superfund, which would pay for injuries to individuals who decided to apply for the administrative relief, he dissented from the study group's recommendation that this be an add-on to the Superfund tax or a similar tax. This recommendation is incorporated as a recommendation into the present Markey-Florio bill, H.R. 2582.

And his reason for that goes to the scope and dimension of the problem question, which you all had discussed today and discussed in some of your previous sessions with CMA and others. Who should be the taxpayers is an issue which he felt that the Commission didn't have enough evidence to give Congress any advice on, so he felt as a matter of principle, that he had to dissent on that.

Third, there is a significant issue outlined in Mr. Lundquist's testimony and referred to in Mr. Freeman's statement, the issue of the relationship between the new administrative remedy, the tier 1 remedy, and the current ongoing litigation of tort claims, the tier 2 remedy, in what are principally State courts at this point.

Mr. Freeman felt, after deliberating over this for the year or so that the Superfund Study Commission held its meetings that there had to be some barrier put up controlling access to tier 2 once a claimant had chosen to pursue his administrative remedy in tier 1. The fear is that a person would seek his administrative remedy and have a recovery there and then use that money to finance his access to tier 2. Or at least the system would be subject to more abuse. His preference was for a binding election in which one chose his easier, quicker recovery in the administrative system, or one chose to pursue a remedy in State courts with its higher uncertainty but with potentially greater rewards.

Another issue that the group did not confront in Mr. Freeman's opinion because the Commission was probably divided on it based on what its minutes revealed—is the issue of punitive damages. In an area of the law where there is a comprehensive scheme of civil and criminal penalties enforceable perhaps through citizen suits as under the Water Act, or at least where the claimant has the ability to go to a law enforcement official at the State and/or Federal level to secure the punishment of the person violating the regulations or standards, he felt that on top of that to allow the plaintiff to go into court and to seek punitive damages was tantamount to allowing a kind of vigilantism, and in his own separate statement, the remark was "vigilantes have no place when the sheriff takes over."

The final area where Mr. Freeman made some comments in his separate statement which were at some variance with the majority was his view of strict liability, both with respect to the view of strict liability under the present law, at least one theory which is set forth in part 3 of the report, and the view of strict liability which the Commission adopted as the one which it would apply to defendants in the so-called tier 1 subrogation action where once the fund has paid out money it goes after an allegedly responsible party. The view of strict liability which was adopted by the Commission, Freeman thought was tantamount to a kind of absolute liability, and was not appropriate.

So those are the basic five areas where he felt compelled to dissent. On many other areas such as in the toxic rulemaking area, he certainly has taken a well advanced position compared with others with whom I have spoken on the defense side, and he spoke for himself. As we went into this Superfund study group, we followed the history of public service within our law firm, Hunton and Williams to leave our clients at the door in such bar activities. He spoke only for himself in his statement and did not represent any client's interest.

We do not represent any clients in this undertaking.

I guess I have just a couple other notes that I would like to make. One is that during the Superfund study group's deliberations Mr. Freeman personally did not feel that he had a lot of understanding of the insurance implications of what the study group was about, and so advising him and subsequently actually advising the study group, we drew upon some experts which we were able to identify in the insurance industry and they devoted some time to reviewing an early draft of the Superfund study group report and out of that—this is reported in the body of the report—came an idea for handling the issue of apportionment of liability, the so-called channeling concept, which Dick Schmalz with the Hartford put forward in an article I have appended to this testimony.

We think that idea certainly deserves some consideration in the context of victim compensation and perhaps also in the context of some amendments to the Superfund act itself regarding cleanup of hazardous waste sites.

The other part of the testimony which—the first part of Freeman's testimony distributed today—tries to relate some of the issues which the Superfund group dealt with in victim compensation with some of the problems we see in our practice and in our studies with respect to the Superfund liability system and we would be happy to talk about that if you would like.

Thank you.

STATEMENT OF GEORGE CLEMON FREEMAN, JR.

BEFORE THE

SUBCOMMITTEE ON INVESTIGATIONS AND OVERSIGHT

OF THE

COMMITTEE ON PUBLIC WORKS AND TRANSPORTATION

UNITED STATES HOUSE OF REPRESENTATIVES

CONCERNING

HAZARDOUS SUBSTANCE INJURY COMPENSATION

JULY 26, 1983

I. INTRODUCTION

Mr. Chairman, Committee Members, Ladies and Gentlemen -- my name is George C. Freeman, Jr. I am a partner in the law firm of Hunton & Williams, with my offices both in Richmond, Virginia, and Washington, D.C. I am also a member of the Virginia, D.C. and Alabama bars.

It might be helpful to indicate briefly where I am coming from on the issues before you today in terms of past and present practice and bar related activities.

My active practice is primarily in administrative law in the environmental and energy areas. During the past decade, I have been senior counsel to the Utility Water Act Group (UWAG) and the Utility Air Regulatory Group (UARG) in EPA rulemakings and appeals under the Clean Water Act and the Clean Air Act, respectively. These clients are ad hoc groups of electric utility systems and their trade associations, the Edison Electric Institute, the National Rural Electric Cooperative Association and, in the case of UARG, the American Public Power Association. In the representation of these groups, my firm has on occasion also participated in rulemaking proceedings under the Comprehensive Environmental Response Compensation and Liability Act of 1980 [the "Superfund Act"]. I also represent the Edison Electric Institute (EEI), the trade association of the investor-owned segment of the electric utility industry, in connection with the current efforts to amend the Clean Air Act. In addition, I am a member of the recently organized EEI Task Force on Compensating Persons Exposed to Toxic Substances.

My firm, Hunton & Williams, represents individual utility companies, oil companies, paper producers, pharmaceutical manufacturers and chemical manufacturers that own or operate facilities that are subject to numerous federal and state environmental requirements and liabilities, including specifically the Clean Water Act, the Clean Air Act, the Toxic Substances Control Act, the Resource Conservation and Recovery Act (RCRA) and the Comprehensive Environmental Response, Compensation and Liability Act (CERCLA or the Superfund Act). As the senior lawyer in the firm's Energy and Environmental Law Team, I have usually been in charge of these efforts.

In bar activities, I have been a member of the Council of the American Law Institute since 1979. I am also a member of the American Bar Association and active in its Section of Corporation, Banking and Business Law. I was a member of the Council of that Section from 1976 to 1979, Chairman of its Ad Hoc Committee on the Federal Criminal Code from 1979 to 1981, and I am presently Chairman of its Program Committee and a member of its Tort Law Reform Committee. I should add that my opinions on the subject matter of this hearing are derived not only from my practice and participating in bar activities but also from my recent experience as one of the twelve members of the Superfund 301(e) Study Group.

I am testifying here today, however, not as a spokesman for my firm or any of its clients or any professional association with which I am connected. The views I express are solely my own, and they should not be attributed to my firm or any of its clients, the American Law Institute, the American Bar Association or the Superfund Study Group.

The Superfund 301(e) Study Group was composed of lawyers from four diverse professional legal organizations: the American Bar Association, the American Law Institute, the Association of Trial Lawyers of America and the National Association of Attorneys General. I was one of the three members designated by the President of the American Bar Association. Congress wanted a diverse group to foster the exchange of varying views, and Congress got it. There are virtually no issues in the current debate over various Congressional "Superfund" toxic injury compensation proposals which we did not discuss in the Superfund Study Group during 1981-82. The debate within our Group on some of these issues sometimes became so lively that it appeared no Report would ever be delivered to Congress. But with a few notable exceptions, such as its view of strict liability under the common law and punitive damages,[1] the resulting Report's discussion of existing statutory and common law is adequate. But as to the Study Group's recommendations, you should be aware that they were not in all respects unanimous. The Group agreed, accordingly, to the inclusion of separate statements of the individual members as a part of the Report.[2]

[2] Superfund § 301(e) Report, Part 1, pp. 286-359; note also the letters and other materials which are included as "Comments

(footnote continued)

For proper perspective on policy alternatives, you need to read these individual views as well as Professor Grad's report for the majority.

Since Weyman Lundquist, another member of our Superfund Study Group, who is scheduled to precede me today, will summarize the Report's recommendations, I will not repeat what he will say. It might be more helpful if I summarized my perception of the positive contributions made by the Report to the overall policy debate and then expressed my reasons for concurring in some but not all of the Report's recommendations. In the area of positive contribution:

1. The Report recognizes that data as to the scope of the problem are not now available -- therefore the problem may be one of perception instead of actuality.[3]
2. The Report correctly interprets the City of Milwaukee and Sea Clammers cases to conclude that no federal "common law" of tort or nuisance exists in this area but that state common law is alive and well.[4]

(footnote continued)

to the Appendices" at the rear of Part 2 of the Report, but which were inadvertently omitted from the Part 2 Table of Contents.

[3] The Superfund Study Group had much the same experience as this Subcommittee originally had in not being able to obtain much information on Superfund related matters from EPA. See e.g., Superfund § 301(e) Report, Part 1, pp. 21-39, 310-311; Part 2, Letters of Dec. 16, 1981, and Mar. 2, 1981, in the Comments to the Appendices. All references to page numbers are to those at the top of pages in the Congressionally printed Report.

[4] See Superfund § 301(e) Report, Part 1, pp. 87, 323-324; Part 2, pp. 151-152, letters of Dec. 16, 1981; Apr. 29, 1982; May 17, 1982, in the Comments to the Appendices.

3. The Report unanimously recommends against creation of a Federal statutory judicial tort or nuisance (Tier Two) remedy.5/

4. The Report recognized the problems associated with the Black Lung Act and rejected it as a model for recommendations in this area.6/

5. The Report rejected endorsement of the Enterprise and Market Share Liability Theories.7/

6. The Report, in recommending creation of a Tier One (administrative compensation system), rejected the notion of retroactivity in subrogation of Tier One claims.8/

7. The Report recommends that injuries covered by Workmen's Compensation be exempt from any Tier One system.9/

8. The Report recognizes that the statutory presumptions proposed for the Tier One administrative system would be inappropriate in the Tier Two judicial system.10/

9. Finally, the addition of Section III B of Report on insurance law and thought-provoking criticism of current joint and several liability rules were major contributions to thoughtful consideration of tort law reform generally.11/ In particular the recommendation of consideration of the substitution of "channelling" for "joint and several

10/ See Superfund § 301(e) Report, Part 1, p. 60.

11/ See Superfund § 301(e) Report, Part 1, pp. 162-192.

> liability" in both Tiers One and Two merits far more attention than it has so far received.12/ The adoption of "channelling" would result in swifter, full compensation with lower transaction costs and the elimination of duplicative insurance. The net result would be better for persons injured or damaged and for the public, which bears the ultimate costs of the system through the costs of goods and services.

Turning to the Report's recommendations, I concur in the recommendation for creation of a Tier One administrative compensation system for the reasons set forth in my separate statement at pages 308 to 310 of the Printed Report.13/ But there are five areas where I have problems with the recommendations and the Report:

1. I did not think we knew enough to make a recommendation to Congress on the source of the Tier One funds. For that reason, I did not concur in the recommendation to fund it through an add-on to the existing Superfund taxes.14/

2. I strongly concurred with Judge Breitel's dissent from the recommended statutory presumptions in Tier One.15/

12/ See Superfund § 301(e) Report, Part 1, pp. 181-183, 258, 324.

13/ For the convenience of the Committee, a reprint of my separate statement in the Superfund Report is reproduced as Attachment A to this testimony.

14/ See Superfund § 301(e) Report, Part 1, p. 245; but see, Freeman's Statement. Part 1, pp. 311-314.

15/ See Superfund § 301(e) Report, Part 1, pp. 213-219; but see Breitel's and Freeman's statements, Part 1, pp. 299-300, 314-318.

3. I joined Judge Breitel and Professors Anderson and O'Connell in deploring the failure to recommend the requirement of a limited binding election between the Tier One administrative remedy and the Tier Two adjudicatory remedy.16/

4. I thought Judge Breitel's criticism of the Report's overbroad description of "Strict Liability" was right on the mark.17/

5. I deplored the failure of our Group to address the punitive damages issue in the Report, despite our consideration of that issue in our meetings.18/

There are a number of bills pending in both Houses that deal with some of the issues we addressed in the Superfund § 301(e) Report. Unfortunately, some of the more interesting of the Study Group's suggestions such as consideration of the substitution of "channeling" for "joint and several" liability as the means for apportioning liability,19/ have not yet made their way into the political debate. Some of the Congressional

"Superfund" proposals, even those in the Senate which supposedly are intended to "implement" the Study Group's recommendations, contain provisions we considered and rejected.

II. AN EXAMPLE NOT TO FOLLOW: THE SUPERFUND ACT

Before I discuss some of the pending bills, I would like to summarize what has happened during the two and a half years since the Superfund Act was enacted because many of the issues raised in the interpretation and application of that act in determining who should pay for cleanup of hazardous wastes are directly relevant to who should pay to compensate persons injured or damaged by these wastes.20/

In the Congressional compromise that enabled the Superfund Act to be adopted in December 1980, the federal cause of action provisions in the Senate Bill21/ were deleted and the Superfund § 301(e) Study substituted. Thus private plaintiffs who seek recovery because of hazardous substances exposure have continued over this period to rely on state law, usually the

---

20/ Part of this analysis of the Superfund Act follows an analysis prepared as a public service by my associate, Alfred R. Light, for the National Science Foundation. See National Science Foundation, An Addendum to a Research Report on Compensation for Victims of Toxic Pollution - Assessing the Scientific Knowledge Base (April 1983) (NSF 83-46).

21/ S. 1480, 96th Cong., 2d Sess. (1980).

state common law of tort and nuisance. To date, there have been relatively few damage awards associated with exposure to toxic substances except for asbestos and some substances which have been the subject of product liability litigation.22/ Despite the small number of awards, a growing number of court suits are being filed which request very high damages. EPA reported in 1982:

> If any of these suits are successful the potential third party damage costs associated with operating hazardous waste facilities would become much larger than currently available data show.23/

Congressional consideration of changes in what are today essentially state statutory and common law rules for compensating those with toxic substance related diseases involves complex interrelationships. As Judge Charles D. Breitel explained in his separate comments in the Superfund 301(e) Report:

> There are inextricable relationships among the issues of responsibility and liability, statutes of limitations, causation, components of damage recovery, latency of harm caused, social cost-benefit analyses, government regulation, and national interest in encouraging some (but not all) hazardous activities.24/

22/ Superfund § 301(e) Report, Part 1, p. 32.

23/ 47 Fed. Reg. 16550 (Apr. 16, 1982).

24/ Superfund § 301(e) Report, Part 1, pp. 295-296.

The witnesses here today are lawyers, but this and other appropriate Committees need to hear about these interrelationships from a broader community of experts, including economists, businessmen and political scientists as well as medical and scientific experts. Your series of hearings, involving witnesses from the scientific, legal, environmental and insurance communities is a useful step in this process.

The tough balancing of social costs and benefits that should be made before any drastic changes are made in liability rules needs information and insights that go beyond the legal profession. Lawyers, whether they usually represent plaintiffs or defendants, stand to profit more and more as litigation escalates; but that is not true of society as a whole. As litigation costs mount, awards increase in number and amount, and insurance premiums escalate. Most of these increased costs are ultimately imposed on the public through higher costs of goods and services. Often the percentage of these costs of the whole system that actually go to compensate persons injured is quite low. We must continually ask ourselves whether those extra, "transactional," costs are justified and if there are not better ways or better systems.

If you do decide that additional legislation is needed, I urge you to take great care in drafting it. To illustrate this point, it might be useful to examine some of the problems that have resulted from the poor drafting of the present liability provisions regarding waste site cleanup in the Superfund Act.

A. Preemption and Savings Clause Provisions

The Superfund Act's preemption provision and savings clauses have created substantial uncertainty and greatly contributed to the volume of litigation.

The Superfund Act's section 114(c), 42 U.S.C. § 9614(c), states in part:

> Except as provided in this Act, no person may be required to contribute to any fund, the purpose of which is to pay compenstion for claims for any costs of response or damages or claims which may be compensated under this title.

This provision has cast a substantial shadow over state superfund-type taxes.25/ The floor debate on this provision, the only legislative history available, is confusing.26/ At

---

25/ See, e.g., Superfund § 301(e) Report, Part 1, pp. 268, 271 and Part 2, letter of May 17, 1982, in "Comments to the Appendices," at the end of that volume. H.R. 6705, 97th Cong., 2d Sess. (1982) (Cong. LaFalce) would have removed these doubts by repealing this provision.

26/ Compare 126 Cong. Rec. S14,981 (daily ed. Nov. 24, 1980) (colloquy between Senators Randolph and Bradley) with 126 Cong. Rec. S15,004 (daily ed. Nov. 24, 1980) (remarks of Sen. Helms regretting the preemption), and see 126 Cong. Rec. H11,788 (daily ed. Dec. 3, 1980) (remarks of Rep. Florio); see Grad, A Legislative History of the Comprehensive Environmental Response, Compensation and Liability ("Superfund") Act of 1980, 8 Colum.J.Envir.L. 1, 31 (1982).

present, at least 35 states, including New Jersey, California, New York, Minnesota, and most recently Missouri, have enacted some type of state superfund legislation.27/ Section 104(c)(3) of the Superfund Act requires that the states provide at least ten percent (10%) of the funds for remedial actions at privately owned sites, fifty percent (50%) of such costs at sites owned by the state or its subdivision.28/ The states must also provide for future, long term maintenance. The extent of this preemption of the state's potential sources of revenues for those purposes is thus no academic matter. The Superfund Study Group recommended "that Congress clarify its intent relating to the preemptive reach of § 114."29/ Any legislative amendments to the Superfund Act should address this issue.30/

27/ United States Congress, Office of Technology Assessment, Technologies and Management Strategies for Hazardous Waste Control 369 (Mar. 1983); Minnesota's Superfund bill, perhaps the most comprehensive yet enacted, passed the Minnesota legislature on May 5, 1983 (H.F. 76).

28/ 42 U.S.C. § 9604(c)(3).

29/ Superfund § 301(e) Report, Part 1, p. 271; *see also* U.S. Congress, Office of Technology Assessment, *supra*, at 368.

30/ Not only should Congress clean up the present ambiguity, but it should also look at the consequences of other proposed changes in that Act in light of this prohibition. For example, several Senate bills would expand the "Superfund" reimbursement to cover "victim compensation" payments which may presently be covered by state victim compensation funds and state workers' compensation programs. Section 114, if not amended, could be interpreted to bar further direct assessment of "Superfund taxpayers" for those state funds.

The Superfund Act's saving clauses have generated some controversy. Section 302(d) of the Act, 42 U.S.C. § 9652(d), provides:

> Nothing in this Act shall affect or modify in any way the obligations or liabilities of any person under other Federal or State law, including common law, with respect to releases of hazardous substances or other pollutants or contaminants.

At least one Senator at one point had the rather unusual notion that the existence of this clause amounted to a Congressional authorization for federal courts to infer or create a federal common law private cause of action for damages.31/ This confusion over the meaning of the Superfund Act's as well as other environmental statutes' savings clauses has led to the unusual attempt to create new federal remedies by modifying such clauses for the stated purpose of creating or "reviving" the federal common law of tort and nuisance.32/ But congressional attempts to create private rights of action in this indirect way would,

---

31/ See 126 Cong. Rec. S15,640 (daily ed. Dec. 16, 1981) (remarks of Sen. Stafford stating that the superfund law "expressly preserved both Federal and state common law," although the Supreme Court has never found a federal private cause of action to exist in this area).

32/ E.g., 126 Cong. Rec. S12,249 (daily ed. Oct. 27, 1981) ("technical amendment" to Clean Water Act in S.1716); S. 2867, 98th Cong., 1st Sess. § 11(c) (1983); see H.R. Rep. No. 98-198 (Part 1), 98th Cong., 1st Sess. 49 (1983); H.R. Rep. No.97-570, 97th Cong., 1st Sess. 21-22 (1982) (H.R. 6307, § 10).

if enacted, prove futile because they would probably be held unconstitutional.33/

The creation of federal remedies (through whatever mechanisms) can preempt state law implicitly as well as explicitly. For example, state punitive damages for nuclear occurrences may be impliedly preempted by the Atomic Energy Act.34/ These cases suggest that great care must be taken by Congress to state expressly and clearly in statutory language the relationship between existing state remedies and any new federal remedy. Both preemption and savings clauses produce confusion and unnecessary litigation when the Congress leaves its intent unclear.

B. Apportionment and the "Joint and Several" Issue

EPA received much criticism in the past for the relatively slow pace of its Superfund cleanup program. The Superfund § 301(e) Report stated, for example:

33/ *See* Superfund § 301(e) Report, Part 2, Letters of Dec. 16, 1981, and May 17, 1982, in "Comments to the Appendices;" *see* pp. 69-74 below.

34/ *See* *Silkwood* v. *Kerr-McGee Corp.*, 667 F.2d 908, 922-923 (10th Cir. 1982), *juris. postp'nd* No. 81-2159 (Jan. 10, 1983). *UNC Resources, Inc.* v. *Benally*, Civ. No. 80-750B (D.N.M. Oct. 12, 1982).

> It has come to the Study Group's attention that there have been some administrative delays in the management of claims for Superfund support in cleaning up hazardous waste problem sites, and . . . that only a small number . . . are likely to be cleaned up by Superfund contributions in the foreseeable future.35/

Other criticisms have been less circumspect.36/

Some trial judges faced with EPA attempts to sue responsible parties for Superfund "reimbursement" *prior to* spending any government funds appear to be growing impatient. For example, a federal district court recently wrote in a memorandum opinion:

> For reasons unclear, neither the United States nor New Hampshire has sought to make use of its own funds for the purpose of emergency clean-up, removal and containment action pursuant to sections 104 and 107 of CERCLA, 42 U.S.C. §§ 9604, 9607 and New Hampshire's Hazardous Waste Cleanup Fund, RSA 147-B (Supp. 1981) ("HWCF") . . .
>
> . . . . .

35/ Superfund § 301(e) Report, Part 1, pp. 270-271.

36/ *E.g.*, Baise and Bourdeau, *EPA's Implementation of the Superfund Response Programs*, 3 Envir. Analyst 3 (May 1982); *Administrative Delays Plague Cleanup Under Superfund, Indiana Congressman Says*, 13 Envir.Rep. (BNA) 167 (Jun. 11, 1982); Pain, *Mega-Party Superfund Negotiations*, 12 Envir.L.Rep. 15054 (Nov. 1982); Rogers, *The Generators' Dilemma in Superfund Cases*, 12 Envir.L.Rep. 15049, 15053 (Nov. 1982) ("EPA and the Justice Department must be more responsive and more consistent, if the CERCLA cases are not to turn into enormous "reverse" class actions that consume millions of dollars in legal fees, retard cleanup efforts, and end up frustrating all involved.").

> The circumstances herein depict federal and state governments which are either unable or unwilling to take the necessary financial steps to protect the public from what are long extant but apparently recently discovered dump sites containing hazardous wastes, and the same plaintiffs are similarly unwilling to proceed against current owners who are in posession of such sites.[37]

While some of the past delays in Superfund cleanup have been blamed on EPA personnel, much of the delay is attributable to Congress' poor draftsmanship. One of the most critical areas has been the Act's failure to articulate expressly and unequivocally who can be held liable for what and when. The Act articulates no principles of joinder or apportionment of liability among liable defendants. It also is ambiguous as to whether "strict liability" was intended to involve traditional balancing notions or to be equated to "absolute liability." Finally, the act and its legislative history are ambiguous as to the extent Congress intended it to be retroactive, and by retroactive I mean to impose liability under federal law on persons for past actions which at the time they occurred would not have been illegal or actionable under federal law.

---

[37] United States v. Johns-Manville Sales Corp., 13 ELR 20310, 20311-20312 (D.N.H. Nov. 15, 1982); appeal docketed No. 83-1152 (1st Cir. Mar. 3, 1983).

Because the Act may cast a broad net of liability apparently to include as jointly liable many who may have had only a tenuous connection to a waste site and whose conduct may have been legal and otherwise nonactionable under then existing law, the relevant principles of apportionment have become very important in presently pending Superfund cleanup cases. Congress, however, refused to address the issue directly. "Joint and several" liability language in early drafts was eliminated without adequate explanation. Comments of Congressmen and Senators during floor debate as to the meaning of this deletion are diametrically opposed.38/ EPA and the Justice Department have asserted a broad application of joint and several

---

38/ 126 Cong. Rec. S14,964 (daily ed. Nov. 24, 1980) (Sen. Randolph); 126 Cong. Rec. H11,787 (daily ed. Dec. 3, 1982) (Cong. Florio), 126 Cong. Rec. S15,004 (daily ed. Nov. 24, 1980) (Sen. Helms). In late 1981, Senator Stafford continued the debate in post hoc legislative history. He stated:

> As disappointing as it is to me, I am realistic enough to recognize that it is the role of modern Washington lobbyists to press their clients' interest to the bitterest end. Those charged with the responsibility for deciding these issues, however, must bear in mind that such arguments are being advanced with a stated goal in mind, not for the sake of an abstract pursuit of justice or accuracy.

127 Cong. Rec. S9335 (daily ed. Sept. 9, 1981). "Joint and several liability" is being challenged in several pending Superfund cases. E.g., U.S. v. Conservation Chemical Co., No.82-0983 (W.D.Mo.); U.S. v. Chem-Dyne, No. C-1-82-840 (S.D.Ohio).

liability notwithstanding the deletion. On the other hand, one distinguished academic commentator has stated that "it is . . . clear that joint and several liability was not intended."39/ The most probable "actual" Congressional "intent" is that Congress deliberately failed to resolve the political impasse leaving to "common law principles to determine when parties should be severally liable."40/

Thus as often occurs, the political compromise to "leave it to the courts" led inevitably to delay and litigation rather than to the rapid cleanup of hazardous waste sites. The lesson to be learned is that legislative compromises that leave statutes fuzzy and unclear and thrust the task of resolving the ambiguities and conflicts upon the federal courts often postpone rather than expedite the solution to the substantive problems to which the legislation is addressed. Given the already overcrowded dockets of our federal district courts, it literally takes years in many instances to get initial decisions. Then decisions in these key test cases are appealed to the overburdened Circuit Courts of Appeals, where eventually conflicting decisions will be handed down. And then, but only

---

39/ 1A Grad, Treatise on Environmental Law, § 4A.04, at 4A-114.

40/ 126 Cong. Rec. S14,964 (daily ed. Nov. 24, 1980) (Sen. Randolph).

when those decisions are numerous enough, will the overburdened Supreme Court grant certiorari to resolve those conflicts. In the intervening time -- five or six years -- everyone involved in the process is forced to litigate the issue where the financial stakes are large. The social costs of such a system -- including the "transactional costs," or to call a spade a spade, the legal fees -- are enormous. If, on the other hand, Congress had fought the matter out and written the legislation carefully and clearly, the beneficial results intended -- cleanup of hazardous waste sites -- could have been obtained much more quickly, and often through voluntary efforts and settlements rather than litigation.

California, perhaps learning the lesson of the folly of leaving such important issues to "common law" development, provided explicit apportionment rules in its 1981 state superfund act.41/ Minnesota also did the same thing in May.42/ Should Congress move forward in this session with hazardous substance injury liability legislation, it should follow the lead of these states and include an addressing of the apportionment problem.

41/ Cal.Health & Safety Code §§ 25360-25366 (1981).

42/ H.F. 76, enacted May 10, 1983.

Furthermore, "joint and several" liability, it is now clear from the Superfund experience, is no answer at all because it simply shifts the burden of seeking contribution and the apportionment of liability among multiple defendants to the "deep pocket" defendant. The Superfund § 301(e) Report recognized this by recommending that "alternative approaches to apportionment" be examined in connection with its notion that "the burden of allocating separate contributions" be placed "among a number of [liable] defendants."43/ One of our most compelling reasons for that recommendation was our concern about rising insurance costs. If everyone in every stage of the industrial process of generating, transporting, or storing hazardous wastes must insure against total liability resulting not only from his own activities but also from the activities of others subsequently in the process, it is obvious that we have duplicative -- indeed treble -- insurance costs imposed on the consuming public. Where multiple generators dispose of their wastes at a common RCRA licensed site -- and with the commonly supervised disposal at such sites encouraged by that law -- imposition of joint and several liability on all who dispose of their wastes there for all that might happen there could well impose insurance costs on U.S. manufacturers that

---

43/ Superfund § 301(e) Report, Part 1, p. 258, 344n.48.

place their products at a severe competitive disadvantage with foreign competitors -- both at home and abroad. As I emphasized in my separate Superfund comments[44] -- and in my earlier writings to my fellow members of that group[45] -- we need to look carefully at where -- and with what effect -- the incidence of the costs imposed by changes in the law will fall. We must take care that in "internalizing" one set of social costs to help one segment of society -- here the costs of cleanup and compensation for the injuries or damages caused by exposures to hazardous substances -- we do not impose unintended and unfair costs on other segments -- such as unemployment or the unavailability of socially desirable goods and services. If you cast the net of joint and several liability wide enough and make the imposition of high costs capricious enough, then the risks of doing business may become so great as to deter people from engaging in necessary or socially beneficial economic activities in this country. A careful balance of competing social values must be made. As Judge Breitel said in his Comments in the Superfund Report:

---

[44] Superfund § 301(e) Report, Part 1, pp. 311-314.

[45] Superfund § 301(e) Report, Part 2, letters of Mar. 2, 1982; Mar. 10, 1982; Apr. 12, 1982 in "Comments to the Appendices."

> There are many hazardous substances and activities which must be balanced against the then - or presently - available alternatives. In preventing many of humanity's ills, disasters, and malnutrition, elimination of hazardous substances without a then-known alternative or one now known, the costs in death, disease, and environmental harm may be or may have been greater than that caused by the hazardous substances or activities. The point is that the pristine jungle is not a safer place for human habitation or activity than the inevitably danger-ridden civilized society which has given us the boon (problem) of enormous growth of population with increasingly greater longevity and health.[46]

Another aspect of the "joint and several" liability debate involves the insolvent "responsible party." To date, EPA's Superfund and RCRA enforcement policy position generally has been that the remaining solvent responsible parties must pay the entire cleanup costs, including the insolvent party's "share," without any contribution from the Superfund. The Fund is used to finance a cleanup only when enough responsible parties refuse to settle for total cleanup costs. In a situation where insolvent parties contributed substantially to the problem requiring cleanup, a solvent responsible party (or parties) is likely to resist a government "offer" to settle because of his recognition that his right of contribution against other responsible parties is a hollow one. EPA officials claimed, however, that this was not a practical problem in the first round of Superfund cases because the generators they targeted generally *are* solvent.[47]

---

[46] Superfund § 301(e) Report, Part 1, pp. 297-298. And *see, generally*, National Science Foundation, *Addendum to a Research Report on Compensation of Victims of Toxic Pollution -- Assessing the Scientific Knowledge Base* (April 1983); Light, *Toxic Injury Compensation: One More Overview of Legislative Proposals*, 15 Nat. Resources L. Newsletter 2, 8-11 (Spring 1983).

Some recent legislative proposals would further delay Superfund cleanup if they are enacted. These proposals would piggyback claims for compensation for damages to person or to property into cleanup proceedings through either broadened citizens suits that permit pendent jurisdiction over claims under state law or through a new federal cause of action[48] or through a private right of intervention in EPA enforcement actions.[49] In my opinion, enactment of either proposal would delay rather than expedite the attainment of the twin goals of (1) protecting of our people and the environment from unnecessary and undesirable waste generation, handling and disposal practices and (2) providing fair compensation to those injured or damaged through the functioning of our economy.

---

[47] A related problem arises when *all* the responsible parties the government can identify are insolvent. The courts in this situation must confront the "clash of policies protecting the environment and policies protecting the bankrupt and its creditors." Rosenberg, *Bankruptcy and Environmental Regulation: An Emergency Conflict* 13 Envir.L.Rep. 10099 (Apr. 1983); *see* Moore, *Bankruptcy Stays Thwarting Cleanups*, Legal Times (May 9, 1983). A bankruptcy stay may frustrate government efforts to force cleanups. *See In re Kovacs*, 681 F.2d. 454 (6th Cir. 1982); *U.S.* v. *Johns-Mansville*, 13 ELR 20310 (D.N.H. Nov. 15, 1982), *appeal docketed* No. 83-1152 (1st Cir. Mar. 3, 1983); *In Quanta Resources*, Civil No. 82-3524 (D.N.J., Jan.24, 1983); *In re Crystal Chemical Co*., Bankr. No. 81-02901-HB-4 (S.D. Tex., filed Jul. 15, 1982); environmental prosecutors can be expected to argue vigorously that "enforcement actions for mandatory injunctive relief to compel environmental cleanup are not subject to the bankruptcy stay." D. Muchnicki, *The Bankruptcy Code and State Police Power Enforcement*, Envir.Prot.Rep. 1, 5 (Nat. Ass'n of Atty. Gen. Mar. 1983). In this as well as the last Congress, Congressman Florio introduced an amendment to the bankruptcy laws that would give priority to government enforcement claims over secured and unsecured creditors; H.R. 2767, 98th Cong., 1st Sess. (1983); H.R. 7172, 97th Cong., 2d Sess. (1982). It is unclear whether the secured creditor whose security is impaired by a government claim will have a right against the Superfund for reimbursement.

The process of enforcement of laws and regulations to avoid or mitigate exposures to hazardous wastes is a police function. Over the years we have learned that law enforcement is best left to the policeman and not to vigilantes. Moreover, we normally do not permit criminal prosecutions to be tried together with civil damage actions. Finally, experience shows that the process of compensation for injuries or damages, whether under an administrative (insurance type) system or a litigative system, functions best where most of those who must pay do so voluntarily. And in a litigative system, the transactional costs are magnitudes lower where actual litigation is the exception and not the rule. If we do not halt the current trend toward encouraging more and more litigation and do not find better means for resolving most of these problems, the whole process will choke on itself, leaving our environment despoiled, those injured uncompensated, our courts hopelessly overburdened and our economy gravely threatened.

---

[48] See H.R. 2867, 98th Cong., 1st Sess. § 11(b) (1983) (modifying RCRA citizen suit § 7002).

[49] E.g., S. 1363, 98th Cong., 1st Sess. § 20 (1983) (giving private parties right to intervene in government RCRA § 7003 suits).

C. Generator ("Vicarious, Strict") Liability

Another issue where Congress was deliberately equivocal concerning the Superfund Act involves the standard of care to which defendants are to be held under the statute. Specific references to "strict liability" were deleted, and instead the Act defines the Act's standard of liability to be the same as that under § 311 of the Federal Water Pollution Control Act.[50] While it is clear that this standard is one form of strict liability for the owner or operator of a vessel from which there is a hazardous release, it is much less certain what the reference means in other contexts such as the liability of hazardous waste generators arising out of disposal of wastes by others at sites off of the generator's property.

---

[50] 42 U.S.C. § 9601(32).

Superfund appears to impose liability for cleanup costs on generators, transporters and owners and operators of waste facilities. However, there are now some indications that courts will not impose liability on those who do not contribute substantially to (are not a legal cause of) the problem requiring cleanup.[51] That is, in the absence of negligence, courts may hold that a generator's activity did not proximately cause the damage resulting from an accident at an offsite disposal facility operated by another.[52]

The scope of generator liability within the context of federal enforcement of RCRA is also a subject of hot dispute today. A question under RCRA section 7003 has been whether a generator is always a person "who contributes to" an imminent hazard at someone else's disposal site. A post-hoc interpretation of these words appears in a Senate Committee report on the 1980 Amendments to RCRA. The report states:

---

[51] *City of Philadelphia* v. *Stepan Chemical Co*., 544 F.Supp. 1135, 1143 n.10 (E.D.Pa. 1982) (dicta); *see State of New Jersey Department of Environmental Protection* v. *Ventron Corporation, et al.*, 182 N.J.Super. 210 (App.Div. 1981) (New Jersey spill compensation Act); Rodberg, *Apportionment of Damages in Hazardous Waste Litigation*, in Mott. ed., Hazardous Waste Litigation 1982 183, 213 (1982); Dore, *The Standard of Civil Liability for Hazardous Waste Disposal Activity: Some Quirks of Superfund*, 57 Notre Dame Law. 260, 276 (1981).

[52] *Cf*. *United States* v. *Wade*, 546 F.Supp. 785 (E.D.Pa. 1982), *appeal pending* No 82-1715 (3d Cir.) (RCRA § 7003 and Superfund § 106 do not apply to past non-negligent off-site generators of wastes).

> For example, a company that generated hazardous waste might be someone "contributing to" an endangerment under section 7003 even when someone else has deposited the waste in an improper disposal site . . . where the generator had knowledge of the illicit disposal or failed to exercise due care in selecting or instructing the entity actually conducting the disposal.53/

Justice Department prosecutors, who have the clearest interest in the broadest possible theory of generator liability under federal statutes, concede that the particular factual setting of an incident is important to deciding whether there should be generator liability.54/ And the Carter Administration's Interagency Task Force on Compensation and Liability for Releases of Hazardous Substances did not consider absolute generator liability to be among its options for liability under the Superfund Act.55/

53/ S.Rep. No. 172, 96th Cong.,2d Sess. 5, reprinted in [1980] U.S. Code Cong. & Ad. News 8605, 8669; cf. U.S. v. Wade, 546 F.Supp. 785, 791 (E.D.Pa. 1982) (the full Senate Committee discarded the strict liability approach).

54/ E.g., see Briefs in pending United States v. Chem-Dyne, Civil Action No. C-1-82-840 (S.D.Ohio) (parties appear to agree that the Superfund Act does not require joint and several liability in all cases); Reply Brief of the United States on Motion for Partial Summary Judgment and Injunctive Relief, United States v. Petro Processors of Louisiana, 2 Chem. & Rad. Waste Rep. 120, 126 (M.D.La. 1981).

55/ See Department of Justice, The Superfund Concept, June 1979, at 74-77.

The generator ("vicarious strict") liability and apportionment of liability ("joint and several") problems are inextricably intertwined, as various commentators have pointed out.

> In the debate some seem to have lost sight of, or at least glossed over, the real significance beyond Congress' omission of joint and several liability. Inclusion of joint and several liability in the statutes would reflect a legislative judgment of public policy akin to what underlies master-servant or partnership vicarious liability. In other words, a generator who is a substantial factor in bringing about some of the injury might constitutionally be held liable for all of the harm caused by the owner/operator of the facility on public policy ground regardless of legal (proximate) causation in the common law sense, or the indivisibility or not of the injury. The absence of such a joint and several liability provision in Superfund means that Congress has not come to grips with any public policy issue.56/

In my view, the single most important issue in the current tide of Superfund litigation today is whether a nonnegligent generator can be held liable for a major share of cleanup costs simply because of evidence demonstrating that his wastes were present when a release occurred or was threatened at a facility handling the wastes of many generators. The potential for grossly disproportionate vicarious liability

---

56/ Rodberg, Apportionment of Damages in Hazardous Waste Litigation, Hazardous Waste Lit. 1932, 183, 204-205 (1982).

explains why some companies refused to settle in the recent Chem-Dyne agreement.

> "We didn't put it there and you'll never take us alive," was the reasoning attributed to some companies by an EPA official.57/

D. Retroactivity

Intimately related to generator liability issues in Superfund litigation is an issue that, quite remarkably, has not been raised directly in the first Superfund suits originated by the United States to reach initial judicial opinions: retroactivity. A court in one Superfund action brought by a state did find that Congress intended for the statute to be applied retroactively in general.58/ Retroactive application of a more stringent liability standard can render an unobjectionable legal standard unconscionable.59/ In addition, retroactive application of a vicarious, strict liability raises

(footnote continued)

justice which underlie these constitutional concepts also serve as the philosophical underpinning for the general rule of construction that a statute is to be given only prospective application.61/ When a New Jersey appellate court was presented with the argument that the liability standard for cleanup costs under the New Jersey Spill Control and Compensation Act62/ was unconstitutional as retroactively applied, the court held that there was no problem because the statute did not actually impose a new "substantive liability." Instead, it held that this state precursor of the national Superfund law "was remedial only, providing a procedure for the imposition of costs to pay for the cleanup of prior wrongful discharges."63/ One legal commentator who has thought about these issues in the context of the federal Superfund Act has adopted a somewhat similar solution. He construes the "due care" defense to liability as

---

(footnote continued)

(unfairness of retroactive application to insurers who relied on the previous law in setting premium rates).

61/ See United States v. Heth, 7 U.S. (3 Cranch) 399 (1806).

62/ N.J.S.A. 58: 10-23 et seq (1977).

63/ New Jersey v. Ventron, 182 N.J. Super. 210 (App. Div. 1981) (emphasis added); cf. State Dept. of Env'tl Prot. v. Exxon Corp., 151 N.J. Super. 464, 376 A.2d 1339 (1977) (constitutional difficulties preclude retroactive application of New Jersey Spill Compensation and Control Act).

preventing the "imposition of strict liability" on past off-site generators under the Act.64/ While this same commentator has concluded that Congress generally intended for the liability set forth in the Act to apply retroactively, he admits that the issue is not free of doubt:

> It is easy to argue, of course, that if retroactive effect were intended, Congress could have simply inserted a clause clearly stating that the liability provisions were to apply to pre-enactment waste generators. The noticeable absence of such a clause may create enough ambiguity to require an examination of the Act's legislative history to determine if Congress displayed a clear intent to permit retroactive construction.65/

The Senate Report on S.1480 explained that the justifications for the imposition of strict liability in the Superfund context were to promote fairness and equity, to encourage the exercise of greater care, and to cause "the costs of injuries [to] be borne by the activities which caused them."66/ But none of these underlying purposes is served through retroactive application of such a standard. As many commentators have pointed out, such application would "externalize, rather than

internalize, costs by imposing liability for harm on innocent parties . . . [whose] conduct which, under the laws applicable at the time, was neither unlawful, nor tortious, nor a nuisance . . . ."67/ Professor Kenneth Abraham of the University of Maryland, said recently in explaining the insurance implications of the combination of strict, joint and several, retroactive liability:

> Recent developments in tort law also may hinder accurate insurance pricing. Such doctrinal innovations as shifting burdens of proof as to causation and apportionment of damages, the market share liabilty [sic] concept, and joint and several liability by independent tortfeasors are not merely alterations in the traditional burdens of proof. In practice, the doctrines enable some plaintiffs to recover damages from defendants who have not actually caused the loss (or the entire loss) in question. Minimally culpable defendants, for example, may be held liable for all damages suffered by a victim when, in fact, his injuries resulted from the combined activities of many other actors. Insurance premiums will have to take account of this liability exposure.68/

Finally, the imposition of these doctrines on a retroactive basis could push the cost externalization over that Plimsoll line of "due process."69/

67/ Cheek, supra, at 167-168. And see my letter to Frank Grad of March 10, 1982, which is included in the "Comments to the Appendices" in the back of Part 2 of the Superfund § 301(e) Report.

68/ Abraham, Cost Internalization, Insurance and Toxic Tort Compensation Funds, 2 Va.J.Nat.Resources L. 123, 129-130 (1982).

69/ Fikes v. Alabama, 352 U.S. 191, 199 (1956) (Frankfurter, J., concurring).

Notwithstanding all this, neither the generators nor the amici Chemical Manufacturers Association initially raised the retroactivity issue in the Wade case, which has become a central focus for judicial interpretation of the Superfund Act. As the United States pointed out in its reply brief:

> Nowhere do the Generators or CMA confront the anomaly created by the decision below: the very same generators who are subject to recoupment after EPA undertakes remedial action are not subject to an order under the endangerment provisions to assist in abating the hazards to which their wastes have contributed.70/

But the anomaly cuts both ways. It would also disappear if the court recognized that no new substantive liability was created under the Superfund Act with respect to past acts, i.e., if a due care standard embodying previous common law is the liability standard of section 107 as applied to past acts. And if this is not the correct interpretation, courts will ultimately have to confront the constitutional questions.

If Congress decides to enact new legislation creating a federal administrative remedy or a federal cause of action for persons who have been injured or whose property has been damaged by hazardous wastes, it should scrupulously avoid imposing liability retroactively. As I pointed out earlier, one

70/ Reply Brief for the Appellant, U.S. v. Wade, No. 82-1715, at 4, Haz.Waste Lit.Rep. 3859 (Apr. 5, 1983).

of the most important decisions in our Superfund Study deliberations was our unanimous recommendation against any form of retroactivity in federal legislation.71/

E. Punitive Damages

Moving from pending Superfund litigation and issues that have been or should have been raised in those cases, to issues in future cases, a major issue is the availability and standard for punitive damages under the Act. This issue is quite recent because the Justice Department had not filed a case in which it felt that it was appropriate to ask for punitive damages until the Western Processing case filed on July 1.72/ An award of punitive damages must follow a defendant's failure "without sufficient cause to properly provide removal or remedial action upon order of the President," actually his designee under the Act--the EPA.73/ In the Stringfellow litigation, for example, the government decided not to pursue a punitive damages remedy because of the necessity for a time consuming issuance of administrative orders which would then be

---

71/ Superfund § 301(e) Report, Part 1, pp. 245-251, 319-320.

72/ United States v. Western Processing, et al., No. C83-252M (W.D. Wa.).

73/ CERCLA § 107(c)(3), 42 U.S.C. § 9607(c)(3); see Exec. Order No. 12316, 3 C.F.R. 168 (1982).

violated. Also in that case, since California wished to seek recovery of its costs in the lawsuit, an enforcement problem could result if the government followed the administrative order rather than immediate litigation route. That is, since EPA questions its own authority to order persons to make payments to a state administratively under Superfund § 106, California might still have to sue the Stringfellow defendants independently to recover its incurred response costs even if the defendants complied with EPA's order.

It is clear, however, that punitive damages requests under the Superfund Act will be forthcoming, perhaps with more cases that could be filed early next year, according to former Assistant Attorney General Carol Dinkins. EPA and the Justice Department may seek such damages in any fact situation where the statute allows and will, of course, seek such awards in egregious cases. However, all the interpretational and constitutional problems we have discussed above with respect to the implication of rights not expressly granted in the statute, the joint and several issue, vicarious strict liability, and the retroactive application of any of these concepts are multiplied when the focus is an award of punitive damages. In addition, while EPA is apparently only now developing its criteria for when it will seek punitive damages, to the extent common law punitive damages requirement such as scienter and outrageous conduct are lacking in those criteria, there obviously will be challenges in the courts to their imposition.74/

Whether or not Congress amends Superfund or RCRA to give persons injured by wastes regulated under either statute federal remedies in addition to those now existing under state law, it needs to face up to the punitive damages issue. In this regard, I repeat what I said in my separate statement in the Superfund Report:

> I also believe that punitive or exemplary damages have no socially desirable role . . . when a comprehensive scheme of regulation such as RCRA, encompassing civil and criminal sanctions, is in place. I regret that my colleagues who were divided over the issue decided not to address it one way or the other in the Report. For my part, I believe that where Congress has exercised its commerce power to impose a comprehensive system of regulation over an industrial activity or practice and elects to leave private remedies to State law, it should nevertheless preempt any State punitive and exemplary damages since in essence they duplicate the criminal and civil sanctions provided in the Federal statute. Vigilantes have no place when the sheriff takes over. In my view, that duplication also constitutes an unreasonable burden on interstate commerce since it may furnish a major deterrent to engaging in

---

74/ To illustrate, in my view if punitive damages are sought where the acts which created the situation involved were not unlawful when they occurred, then the statute must face the constitutional hurdles applicable to federal criminal statutes and would violate the Ex Post Facto clause. A good discussion of the constitutional issues raised by punitive damages is Wheeler, The Constitutional Case for Reforming Punitive Damages Procedures, 69 Va.L.Rev. 269 (1983).

> worthwhile economic activity. A third reason is that unless class actions are to be required, permitting punitive damages to be imposed on activities regulated under RCRA might result in overcompensation of a few claimants and their lawyers to the detriment of many equally worthy claimants.75/

F. Financial Responsibility Requirements

There are other important policy issues regarding the present Superfund Act which are the subject of an ongoing policy debate. For example, the Superfund Act contains mandatory financial responsibility requirements as part of its scheme of statutory liability for hazardous waste releases. These regulations are to go into effect no earlier than December 11, 1988. The Act attempts to restrict the contractual freedom of insurers providing coverage by providing for direct actions against them.76/ The Act also "nullifies policy terms and conditions essential to assuring policyholder compliance with applicable laws and regulations and contractual undertakings by providing that insurers may not invoke these terms and conditions as defenses to payment."77/ These and other requirements could make liability insurance "extremely difficult to obtain

76/ 42 U.S.C. § 9608(c).

77/ Cheek, supra, at 171.

and terribly costly, particularly if the liability concepts in CERCLA are retained."78/

Insurers are not likely to submit voluntarily to a regulatory requirement that they compensate victims of their insured regardless of the intentional or grossly negligent nature of the latter's behavior.79/ By apparently trying to make an insurer's liability essentially coextensive with those of his insured, the Superfund Act approaches national insurance regulation, an area that has long been left to the states.80/ Insurers' resistance to national regulation generally, to interference with insurance contractual relationships, and to the Superfund Act's liability scheme with its potential for unlimited exposure could "have a dramatic impact on both the availability and affordability of insurance protection . . ."81/ This impact would undermine the cost spreading assumptions upon which the Superfund Act's liability/financial responsibility system is based.

78/ Id., at 174.

79/ Abraham, Cost Internalization, Insurance, and Toxic Tort Compensation Funds, 2 Va.J.Nat.Resources L. 123, 146-147 (1982).

80/ See Prybutok, Federalism Without Washington: Insurance Regulatory Environment in the United States 12 Publius J. Federalism 79 (1982).

81/ Cheek, supra, at 163.

I summarized this issue during the Superfund § 301(e) deliberations as follows:

> Most courts and commentators have not believed that the "deep pocket" was the sine qua non of social desirability and that having found the pocket ends the matter. Rather they have recognized that effects, both primary and secondary, on society, as well as ideals of fair treatment for individuals, have to be brought on to the balance. Thus, to me retroactive imposition of costs on an industry may be socially desirable if those costs can be spread to one portion of society through insurance (other insureds) and/or another through increased prices (consumers). Once a strict liability system, such as workmen's compensation, respondeat superior, etc., emerges from a successful transition phase, that is what normally occurs. But I want to be relatively certain that cost spreading is what will in fact occur, before I sign off on initiating such a process. Likewise, I want to know the probable social costs of the transition itself, its probable duration, and the likelihood of its successful termination.82/

The history of the Superfund Act's implementation since December 11, 1980, suggests that Congress did not consider the likelihood of cost spreading or the fairness of its new liability regime during the hurried lame duck session in which it hastily drafted the provisions of the Act.

82/ Letter of March 10, 1982, Superfund § 301(e) Report, Part 2, pp. 5-6 (Comments to the Appendices).

G. Tax Equity

Another important problem that has arisen in the implementation of the Superfund Act which also has obvious import for any victim compensation funding scheme is tax equity. The problem exists whether or not there is subrogation by a compensation fund against potentially responsible parties for claims paid. Fairness requires that those who provide the "up front" money for a fund should be roughly the same persons who are the potential subrogees. The issue is, if anything, more important where identifiable responsible parties are non-existent or judgment-proof or where there is no subrogation. In these cases, the ultimate incidence of a claim falls on the special taxpayers collectively.

To the extent that the special taxpayers, even collectively, pay costs largely attributable to other causes of disease (*e.g.*, a claimant's own habits, or his exposures to hazardous substances generated by non-taxpaying industries), the system distorts the marketplace for the products or services of the taxpaying industries and in effect forces their consumers to subsidize persons injured in whole or in part by other products or causes.83/

83/ *See* generally Klemme, *The Enterprise Liability Theory of Torts*, 47 U.Colo.L.Rev. 153, 156-165 (1976).

The Superfund Act's taxing scheme basically assumes that the oil and chemical industries are collectively responsible for the hazardous waste problem sites serious enough to require disbursements from the Superfund to finance remedial actions. EPA's priority lists of sites requiring cleanup, however, have included many sites which have absolutely no connection with either industry. For example, some western states have listed abandoned coal mines as sites. The chemical industry persuaded EPA to mitigate this unfair situation by considering "a Fund financed cleanup of [mining] sites only after all available enforcement efforts fail."84/ The basic problem, however, is that the "wrong" industry in these cases is being taxed.

Furthermore, there is some indication that the potential for abuse of special funds is greater than where a government program is funded by general tax revenues. Periodic scrutiny incident to the annual budget and appropriations process may be less rigorous, based on recent experience with the Federal Black Lung Benefits program and the New Jersey Spill Compensation Fund.85/ Former OMB official Robert G. Penner, now

---

84/ EPA Guidance Memorandum on Establishing National Priorities List Under Superfund (Dated June 26, 1982), 13 Envir.Rep. (BNA) 339, 341 (Jul. 2, 1982).

85/ See Lopatto, Amendments Fight Excesses of Black Lung Statute, Legal Times (Mar. 22, 1982); N.J. Auditors Question

(footnote continued)

at the American Enterprise Institute, recently concluded, "the real problem is the lack of careful scrutiny of these things."86/ Funding a Federal administrative program for providing compensation to persons injured by hazardous wastes by an "add on" tax on the oil and chemical industries without knowing what impact the present tax is having on their ability to compete in international trade or what incidence the additional tax would have would be irresponsible. As I said in my Separate Statement in the Superfund Report:

> Based on the information available to the Study Group -- or, more accurately, the lack of information -- I cannot join in the Group's recommendation that the Tier One System be funded by a special tax on the chemical and oil industries, and perhaps other selected industries, rather than from general tax revenues. The Study Group knows virtually nothing about the probable magnitude of direct costs of a Tier One system. Those costs would include funds paid to claimants and administrative costs. Potential claims would include (a) those attributable to exposures to wastes disposed of prior to

Spill Fund Management Controls, Hazardous Waste Lit.Rep. 2,444 (May, 18, 1982). Effective Date of New York Bottle Law Delayed by Measure Approved by Governor, 14 Envir.Rep. (BNA) 242 (June 6, 1983) (includes report on May 13 audit report by N.J. state legislature's Division of State Auditing on N.J. Spill Compensation Fund).

86/ Hershey, U.S. Insurance: Critics Grow, 131 N.Y.Times (Jun. 8, 1982), at 1, col. 2; 6, col. 1.

the enactment of any Tier One system and (b) those resulting from exposures to wastes disposed of after that date. The special tax the Study Group proposes would have to fund the total costs of "pre-enactment" disposal based claims.

It is reasonable to suppose that most of the pre-enactment activities involving waste transportation or disposal were not licensed under RCRA, while virtually all of the post-enactment activities will be licensed. Little is known about the actual nature, extent and location of hazardous wastes disposed of in the past across this country. Also, virtually no information is available on the nature and extent of any personal injuries or property damage such wastes may have caused. Turning to claims based on future activities, the potential costs of a Tier One system are also equally unpredictable. It is reasonable to suppose that the frequency of claims based on future disposal is more controllable because of the much greater care RCRA licensing will require. But there is always the problem that things viewed as harmless from today's knowledge may prove hazardous from tomorrow's hindsight. The only way to guard totally against the dangers of the currently unforeseeable consequences of economic activities is not to undertake them. But I do not see now anyone could seriously advocate society's prohibiting all activity that has not been proven to be "risk free." The economic and political consequences of imposing a "risk free" standard of care on all economic activity would literally wreck our society.

The Parkinson's law of bureaucratic programs insures that claims will be made and money spent under any government compensation system. If in such a system cancers which have multiple actual causes are presumed by law to have been caused solely or primarily by exposure to hazardous wastes, the potential for abuse is apparent. Thus while we could be confronting potential claims that aggregate only several millions, these claims might soar into billions. Indeed, any dollar estimates of the costs of a Tier One system made in the near future may prove as erroneous as those made for the Black Lung Fund when it was amended in 1977. The principal incidence of these unknown costs would fall, through the Tier One tax, on the chemical and oil industries. We have no idea what the economic effects would be on these industries and our economy.

In contrast, we know that our American economy is part of a world-wide economy, that many American industries are now being severely challenged by foreign producers and that our economy is in the midst of a severe recession. The day-to-day livelihood, health and security of our people depend upon the continuing ability of our domestic industries to compete successfully with foreign producers. This reality leads me to conclude that proponents of funding a "Tier One" system through increases in the current Superfund Act tax on specific American industries should have the heavy burden of proving that its incidence would not impede the ability of our domestic producers to compete with foreign producers in our own and foreign markets. If the ultimate result of this Group's proposals and other efforts to internalize the social costs of activities that produce hazardous wastes is to impair substantially that ability of our domestic industries to compete with foreign producers, then not only would these

> efforts at internalization fail, but also other direct and indirect external social costs would be visited on other citizens. Those external costs could substantially exceed the external costs now being borne by others because of hazardous wastes disposal.
>
> In summary, we must be careful in righting wrongs flowing from incomplete internalization of the social costs involved in the generation and disposal of hazardous wastes not to go overboard and impose a whole new set of non-internalized social costs -- loss of trade, unemployment the disappearance of useful products -- that are equally capriciously and unfairly imposed on other segments of our society. Two wrongs can not make a right.[87]

H. Intergovernmental Relations

An additional reason for the delays in implementing the Superfund program, which has import for any victim compensation plan, has been friction between the federal and state levels of government created by the hierarchical model of federalism upon which the intergovernmental relations in the Superfund program is based.

Interestingly, the Superfund Act's inter-governmental relations were a very controversial aspect of the debate over the Act in the House of Representatives during 1980.

---

[87] Superfund § 301(e) Report, Part 1, pp. 311-314. The analysis of these effects might be an appropriate role for the Congressional Budget Office.

Congressman Stockman led the critics of this aspect of the legislation:

> We have an open-ended enabling statute that makes EPA the czar, and I say this without hyperbole -- makes EPA literally the czar over every hazardous waste site in the entire country, and that includes every landfill, every waste site, every junkyard, every leaching pit, every industrial lagoon on the back of an industrial property, every municipal dump, even every backyard rubbish pile that has been accummulated anywhere in the country . . . The EPA has plenary power, and there is absolutely no guidance as to where all these costly activities to clean up hazardous waste will be triggered.88/

The House bill upon which Congressman Stockman was commenting (H.R. 7020) is similar in most aspects of its intergovernmental operation to the Act which passed. Essentially, that Act authorizes the President to undertake any "response measure consistent with the national contingency plan [which he] deems necessary to protect the public health or welfare or the environment."89/ However, it requires that the President consult with the state and obtain numerous state commitments before taking action.90/ The state role is that of order-taker, not that of a partner.

88/ 126 Cong. Rec. H9439 (Sept. 23, 1980) (remarks of Congressman Stockman).

89/ 42 U.S.C. § 9604 (a)(1).

90/ 42 U.S.C. § 9604(c).

Congressman Stockman's proposed alternative to the broad delegation of authority to EPA evident in the Superfund proposals was a grant program for the states to provide money to clean up inactive waste sites, distributed mainly on the basis of a formula tied to population and industrial production. Congressman Florio, in defense of his H.R. 7020 and in opposition to Stockman's alternative, stated:

> EPA, under this proposal would provide formula grants to states with approved plans, after we went through all of the time necessary to get those plans formed . . . The arguments against the substitute are fairly obvious: Time and delay. Time is of the essence in many of these instances. The need is right now. I can point to some 397 sites . . . EPA is already involved and has identified some 397 specific sites that they are at work on. So we do not have the time to develop these programs . . . Many states, quite frankly, are not interested and are not capable of going forward and they do not want to. They want to defer to the Federal Government . . .[91]

When the Senate compromise bill reached the House in December, Congressman Dannemeyer briefly referred in floor debate to the defeated Stockman proposal:

> If there were no other way to attack the hazardous waste problem except through EPA, perhaps a case could still be made for this bill. After all, no one is arguing that the waste sites should not be cleaned up. But, to assume that only EPA can do the job, or do it best and quickest as this bill assumes,

---

[91] 126 Cong. Rec. H9441 (daily ed. Sept. 23, 1982).

> flies in the face of historical experience. Since when did a Federal regulatory agency ever move quickly on a problem, to wit RCRA, or solve it efficaciously, to wit -- air and water pollution . . . . [I]t may be that state government would be able to handle the problem, which suggests that the block grant to states approach, as suggested by our distinguished colleague from Michigan (Mr. Stockman) would be preferable to this means.92/

Congressman Rudd also praised the Stockman alternative:

> A commendable alternative approach offered by the gentleman from Michigan (Mr. Stockman) . . . would have provided a block grant to the states. By this method, the states would be able to set up procedures to deal with the hazardous waste sites within their individual borders according to the priorities they determine . . . . Rather, this bill will perpetuate a Washington based "solution" administered through the Environmental Protection Agency . . .93/

In light of the states' experience with the practical operation (or, more accurately, general paralysis) over the past months, Congressman Stockman's block grant alternative to the present Superfund dole system merits reconsideration. Unfortunately, Congressman Florio's hope that EPA would act expeditiously on cleanup has not materialized.

92/ 126 Cong. Rec. H11,797 (daily ed. Dec. 3, 1980).

93/ 126 Cong. Rec. H11,802 (daily ed. Dec. 3, 1980).

In our Superfund Report, spurred on by the dissatisfaction of the states with the way the present Superfund had been administered as expressed eloquently by our three state attorneys general, we did not suggest that the federal administrative compensation scheme follow the pattern of that Act. We turned instead to the Clean Water Act for a pattern of federal-state cooperation that has worked well in the past and is working well at present.[94] Should Congress choose to go forward with any legislation in this area, it would do well to heed that advice.

III. PENDING LEGISLATION

There are many hazardous substance compensation proposals now pending in Congress.[95] Most of the proposals seek to expand the Superfund Act's liability regime to provide for coverage of personal injuries. Congressman John J. LaFalce's H.R. 2330 and H.R. 2482 are virtually identical to his H.R. 7300 of the last Congress, except that the federal agency designated to administer his compensation system has shifted from EPA to HHS.

---

[94] Superfund § 301(e) Report, Part 1, pp. 252-254, 307, 328-329 n.6.

[95] The best comprehensive overview of legislative proposals in the trade or legal press is Ember, Legal Remedies for Toxic Victims Begin Taking Shape, 61 Chem. & Eng. News 11 (Mar. 28, 1983).

Congressman James J. Florio of New Jersey and Edward J. Markey of Massachusetts have introduced a RCRA amendment, H.R. 2582. In the Senate, the "Superfund" proposals include S.917 and S.945, Senator Robert T. Stafford's and Senator George J. Mitchell's rework of the provisions of S.1480 which were subsequently deleted from the Senate Bill in the 1980 compromise that permitted enactment of the Superfund Act. Senator Mitchell has also introduced S.946, which implements some of the Superfund § 301(e) Report's recommendations but departs from them in several important respects.

These proposals are being widely discussed. For example, the Center for Environmental Management and Inside EPA Weekly Report conducted a briefing on "victim compensation" in April. In May, the ABA's Standing Committee on Environmental Law devoted its annual conference at Airlie House to an analysis of these proposals. More important, the Reagan Administration has taken the matter seriously enough to create a major interagency task force, now at the White House Cabinet Council on Legal Policy, to examine a number of victim compensation options, involving representatives from the Departments of Commerce, Labor, Justice, EPA, HHS and OMB. The Chemical Manufacturers Association, the National Association of Manufacturers, the Business Roundtable, the American Petroleum Institute, the Edison Electric Institute, the American Paper

Institute/National Forest Products Association and various bar groups have organized studies of the issues involved in these proposals. One of the most important bar efforts now underway is by the Ad Hoc Committee on Tort Law Reform, of which, as I indicated earlier, I am a member, of the ABA's Section of Corporation, Banking and Business Law.[96]

The presently pending "Superfund" or RCRA proposals are part, and perhaps only a small part, of the overall Congressional debate concerning toxic exposure compensation. Congressman George Miller's bill in the 97th Congress, H.R. 5735, has been redrafted in the area of occupational disease compensation. The new bill, H.R. 3175, is designed in large measure to replace asbestos tort litigation with an administrative compensation plan. The Asbestos Compensation Coalition, an industry group, has developed its own occupational disease compensation plan. South Carolina's senators have introduced a brown lung bill.[97] Representative Thomas A. Daschle and many others have introduced bills to compensate those who were exposed to Agent Orange in the military.[98] Senator Robert W. Kasten, Jr.'s, industry-backed federal product liability reform legislation, S. 44, which the Commerce Committee reported in the 97th Congress, has already been the subject of hearings in the new Congress.99/ The oil spill compensation plans which have been debated over the past several Congresses have re-emerged.100/ Radiation exposure is the subject of Senator Orrin G. Hatch's and Representative Paul Simon's bills.101/ Rep. Albert Gore, Jr., has been holding subcommittee hearings on toxic exposure compensation in the House Science & Technology Committee. Rep. Don Albosta has asked the Congressional Research Service to examine toxic exposure compensation legal issues and their ramifications. Congress' Office of Technology Assessment recently completed a major study, which recommended "programs to provide assurance that in the event of damages to health or the environment, or indirect economic effects, injured parties will be able to obtain equitable compensation expeditiously."102/

102/ Congress of the United States, Office of Technology Assessment, Technologies and Management Strategies for Hazardous Waste Control, Summary (Mar. 1983), p. 32.

The lame duck Congress last winter enacted an "orphan drug" act containing a provision requiring HHS to develop tables relating radiation exposure levels to the probabilities of diseases.103/ These tables may be intended to serve as the basis for legislation in the radiation compensation area, perhaps similar to Senator Hatch's or Representative Dan Marriott's tort claims procedure for cancer allegedly related to nuclear fallout.104/

I will not attempt to describe comprehensively each of these toxic tort proposals. But I will instead discuss the key details of the "Superfund" and "RCRA" compensation proposals now pending in the House and how they might affect the existing Superfund Act problems I discussed earlier.

A. H.R. 2330 and H.R. 2482 -- The LaFalce Administrative Compensation Plan.

Congressman John J. LaFalce's toxic injury compensation bills, H.R. 2330 and H.R. 2482, are virtually identical to the bill he introduced when the Superfund § 301(e) Report was released late in the second session of the 97th Congress.105/

103/ Pub.L. No. 97-414, § 7(b) (1983).

104/ S.921, 98th Cong., 1st Sess. (1983); H.R. 6052, 97th Cong., 2d. Sess. (1982).

105/ *Compare* H.R. 2330 and H.R. 2482, 98th Cong., 1st Sess. (1983) *with* H.R. 7300, 97th Cong., 2d. Sess. (1982). The only

(footnote continued)

There are only two changes from that earlier legislation. First, the federal administration of the proposed "victim compensation" plan has been changed from EPA to the Department of Health & Human Services.106/ The second change is: the new bill requires that a defendant "fail to establish . . . that . . . [a] release was not the result of a failure of the defendant to exercise due care" in order to make out a defense to liability under the Act.107/ This was a change from the requirement in the earlier bill that the defendant must prove that a "release was not the result of a failure of the defendant to exercise due care" to avoid liability.108/

Congressman LaFalce's proposal is, except for the statute of limitations change which distinguishes H.R. 2482 from both H.R. 2330 and H.R. 7300, identical to H.R. 7300 in the last Congress.109/ As such, unlike S.946, Senator Mitchell's

---

(footnote continued)

difference between H.R. 2330 and H.R. 2482 is that H.R. 2330 starts the running of the statute of limitations upon discovery of a disease, and H.R. 2482 starts the running only upon discovery of a disease and its cause. H.R. 7300 was like H.R. 2330 in this respect.

106/ Compare H.R. 2330, 98th Cong., 1st Sess. §§ 3(3), 4(7), 102(b)(7), 201, 301 (1983) with H.R. 7300, 97th Cong., 2nd Sess. §§ 3(3), 4(7), 102(b)(7), 201, 301 (1982).

107/ H.R. 2330, 98th Cong., 1st Sess. § 101(c)(3)(B) (1983) (emphasis added).

108/ H.R. 7300, 97th Cong., 2d Sess. § 102(c)(2)(1982).

109/ See 127 Cong.Rec. H.8490 (daily ed. Oct. 1, 1982) (Cong. LaFalce's remarks noting that H.R. 7300 was drafted "over 1 year ago.").

"301(e)" bill, it has no direct relationship to the Superfund Study Group's recommendations. Although there is some coincidental similarity between the Study Group's recommendations and LaFalce's bill in the creation of an administrative compensation remedy to supplement remedies in the courts, H.R. 2482's approach goes beyond the Superfund Study Group's recommendations in many respects. More important, it creates the federal cause of action for pollution-caused injuries and illnesses which the Study Group unanimously rejected. While the bill creates a liability section outside the Superfund Act, unlike Senator Stafford's and Senator Mitchell's approaches, the identified responsible parties under LaFalce's bill are virtually identical to those in the Superfund Act.110/ They are the owner and operators of a waste site, transporters, and those who arrange for disposal or transportation.

The federal cause of action that would be created includes a broad presumption of causation for a plaintiff who shows that his exposure was "at such a level and for such duration as would be reasonably likely to cause or significantly contribute to the class or type of injury, illness, or damage allegedly suffered . . ."111/ An extremely broad variety of

---

110/ Compare H.R. 2330, 98th Cong., 1st Sess. § 101(a) (1983) with CERCLA §107(a), 42 U.S.C. § 9607(a).

111/ H.R. 2330, 98th Cong., 1st Sess. § 102(a)(1) (1983).

evidence is declared to be "relevant" to a causation determination, similar to provisions in S.1480 and Senator Stafford's S.917.[112] The presumptions in these bills go considerably beyond the presumption the Study Group recommended, although I think that our experience with the Black Lung legislation proves that the statutory presumption approach is unwise no matter how narrowly such a statutory presumption is drafted.

Under the LaFalce bill, jurisdiction to make awards would exist "in any court of competent jurisdiction in any State" in addition to the federal courts.[113] It also contains an unusual state law "preemption" provision intended to force state workmen's compensation boards to award claims based on the federal statute's eligibility criteria. For example, one provision states:

> In any administrative or judicial proceeding under a State's workers compensation law, the presumption of cause provided by section 102(a)(1) shall constitute the law of such State.[114]

This provision is premised on the assumption that Congress can constitutionally rewrite state law where it conflicts with federal policies rather than to write a federal law which would then displace state law through traditional preemption. In my view, this approach may be constitutionally defective if anything remains of National League of Cities v. Usery [115] after the Supreme Court's recent opinions in FERC v. Mississippi[116] and EEOC v. Wyoming.[117] I should add that the Superfund Study Group considered this approach but rejected it on policy as well as legal grounds.[118]

---

[112] Compare H.R. 2330, 98th Cong., 1st Sess. § 102(b) (1983) with S.917, 98th Cong., 1st Sess § 5(a) (1983) (adding CERCLA § 107(c)(2)).

[113] H.R. 2330, 98th Cong., 1st Sess. § 103(a) (1983).

[114] H.R. 2330, 98th Cong., 1st Sess. § 104(b) (1983).

Turning to the bill's administrative compensation plan (which would exist in addition to the federal cause of action), it is completely federal, located in a federal agency board funded by federal taxes with federal judicial review of agency decisions. Although the locus of the plan's administration now would be HHS, rather than EPA, the federal agency's duties remain the same: (1) certify "releases" of hazardous substances, (2) certify "victims" of exposure to hazardous substances, (3) pay medical and economic loss benefits to certified "victims," and (4) pursue allegedly responsible parties in subrogation actions. The plan would be funded by a Toxic Victim Compensation Trust Fund which draws funds from the "unobligated balance" in the "Superfund" "at the time any benefit is awarded to a victim of a release."119/ The Victims Fund is to be reimbursed by subrogation actions and is also to get loans from the Treasury. The bill authorizes appropriations to Treasury to make these loans.120/ Thus, unlike the 301(e) study group's recommendations, the LaFalce bill establishes no new tax on industry to fund the toxic victims compensation program.121/

[117] ___ U.S. ___, 103 S.Ct. 1054, 75 L.Ed.2d 18 (1983).

[118] Whether constitutional or not, this "indirect" preemption approach is contrary to the fundamental principles of "our federalism" as I understand them. See note 6 to my separate comments in the Section 301(e) Report at pages 328-329.

B. H.R. 2582 -- The Markey/Florio Bill

Congressman Markey has stated that "this legislation is modeled -- with some changes -- after a proposal resulting from a thorough study of victim compensation mandated in the 1980 Superfund law."122/ But those changes are rather significant. The major one is that the bill creates the federal cause of

---

119/ H.R. 2330, 98th Cong., 1st Sess. § 402 (1983).

120/ *See* H.R. 2330, 98th Cong., 1st Sess. §§ 402-405 (1983).

121/ Toxic Victims Compensation, A Speech by the Honorable John J. LaFalce before the Center for Energy and Environmental Management, April 5, 1983, Capital Hilton, Washington, D.C., p. 9.

122/ Statement of Rep. Edward J. Markey (Mar. 24, 1983); H.R. 2582, 98th Cong., 1st. Sess. (1983) (jointly referred to Ways and Means and Energy and Commerce committees).

action which the Superfund Study Group rejected. The federal cause of action explicitly provides for strict, joint and several liability, and damages for pain and suffering. Moreover, it would supplement rather than displace duplicative or conflicting state law remedies.

Turning to the administrative plan proposed in the bill, although it contains some problems which I will discuss later, it is a useful step in the right direction. The proposed administrative compensation plan would permit EPA to award compensation for physical injuries and limited economic loss where a person has "suffered a physical injury or illness caused by exposure to a hazardous substance."123/

What distinguishes this bill from other pending bills in the House and Senate are the limitations which have been built into its "Two Tier" approach. Many of these limitations, which are generally not included in the other toxic injury compensation bills, were also included in the Superfund § 301(e) Report's proposed plan. For example, the liability system is said not to be imposed retroactively in the sense of reimbursement of the government fund by responsible parties.124/

123/ H.R. 2582, 98th Cong., 1st Sess. § 9012(a) (1983).

124/ Nevertheless, the system may in practice operate retroactively unless the provision is rewritten so as to exclude application of the new liability on the basis of activities of the alleged defendant rather than subsequent exposure of the plaintiff.

While a kind of joint and several liability is imposed, liability generally is imposed only for exposures occurring while one has possession or control over a hazardous substance or if one owns or operates a site at which a person is exposed.

The liability is also not imposed on an owner or operator who did not know or reasonably should not have known that a substance was located at a facility when he acquired the site or in which no action or inaction of such a person caused or contributed to an exposure. If an exposure results from a federally permitted release, the defendant is not liable absent, at a minimum, negligence. Further, the results of an administrative proceeding may not be introduced into evidence in any court action. There is also a collateral source offset for any social insurance program such as medicare and medicaid and for private insurance in both systems. Thus, both the administrative compensation and federal cause of action systems are "excess liability" systems only. In addition, any person covered by workers' compensation is excluded completely from recovery under either system.

All of these limitations were discussed in the Superfund 301(e) Report, and most were recommended. Unfortunately, H.R. 2582 also picks up some of the objectionable recommendations of that Report, including a statutory presumption of causation in the administrative compensation system. As the

Study Group recommended, however, the presumption is not applied in the federal cause of action, although health effect documents prepared for use in connection with such presumptions may be introduced in a court action by any party. The administrative system is funded mostly by oil and petrochemical taxes and to a lesser extent by a waste-end tax as is the Superfund Act's "post-closure" fund.

I believe that H.R. 2582 in its present form has three major flaws. For the reasons I gave in my separate statement in the Superfund Report, I believe the special tax and the statutory presumptions provisions are unsound.[125] And like all of my colleagues in the Study Group, I believe it unwise to superimpose a duplicative federal cause of action on to existing state tort law.

One of the reasons I, as an individual member of the Superfund Study Group, was not willing to recommend a federal cause of action in the tort area is that I believe that the present tort system, as distinguished from an administrative system, is enormously inefficient. I have no way of knowing with exactness the proportion of the billions of dollars that are now being spent in the form of compensation payments, insurance premiums or legal fees, or support of the court system, but I have the idea that only $1 out of every $3 goes to a victim. The other $2 go to the system. Therefore, I think an administrative system which can cut down on those transactional costs is a desirable thing. But going forward with an add-on federal system that just builds on top of it all the problems that we have with the present state systems is no real answer.

---

[125] Superfund § 301(e) Report, Part 1, pp. 311-314 (special tax), pp. 314-319 (statutory presumption).

I would also like to point out that that is not the only reason I was opposed to a federal cause of action. I also think it was not the only reason that led us as a group not to recommend that you consider a federal tort remedy. Intellectually, some of us recognized that if we were to recommend such an alternative to you, we would have to face up to, and make recommendations to you on, three important aspects of such a system. First, we would have to tackle the transactional costs issue. That is legal fees. That is the contingent fee. Given the composition of our group, we knew that we could never unite in a recommendation to you to abolish contingent fees and substitute court-approved payments. Personally, however, I think if you are going to enhance substantially the likelihood of recovery, the case for contingent fees goes down and the case for court-approved lawyers' fees based on reasonable hourly rates goes up substantially.

Second, we would have had to address and make recommendations to you on subjectively determined damages. By "subjectively determined," I mean damages such as pain and suffering or punitive damages, which really cannot be objectively quantified, and therefore the award of those damages lies largely with the prejudices or inclinations of the person awarding them.

Third, we would need to face up to the issue of preemption. If Congress were to create a federal cause of action, it seems to me you should make it the exclusive remedy and preempt contrary state law.

If Congress wants to enact a federal cause of action provision and it faces up to these key issues, then a revised H.R. 2582 could be the vehicle for sound legislation in this area. Suppose the strict liability cause of action linked to control over a waste, rather than duplicating state tort law, provided the exclusive tort remedy. There would be no costly cross actions in cases where workers' compensation applied, no actions where public or private insurance covered the costs of an injury, no contingent liability in situations where exposure occurred after a hazardous substance has left one's control, no retroactive application of the strict liability system. In addition, liability for hazardous substances exposures would be uniform throughout the United States with access to the federal courts eliminating conflict of law, choice of law, and many jurisdictional questions. This would end the forum-shopping which presently goes on in many toxic tort cases.

Suppose further that the administrative compensation system were limited to "orphan sites" for which no responsible party could be sued (like California's Hazardous Substance Compensation Account),[126] and that anyone claiming against the Fund would be barred from bringing a lawsuit against anyone for the same exposure. Then use of the fund and litigation would be properly limited. And suppose that the tax funding the plan was a fair tax on all the industries responsible for exposures or from general revenues.

With amendments carefully drafted along these lines, the Markey/Florio bill could provide for a two-tier toxic substance compensation approach which might be preferable to the present system.

Another legislative toxic substances proposal that merits serious attention is the recent state-level proposal of the North Carolina Governor's Waste Management Board.[127] In North Carolina at least, that Board felt that the need for any administrative compensation system had not been demonstrated. The

---

[126] Cal. Health & Safety Code §§ 25300-25611 (1981).

[127] *See* Attachment C to this statement.

Board recommended, however, a new statutory prospective strict liability system in which generators and those in possession of a substance would be held liable for damages arising out of a statutorily defined hazardous waste occurrence. Generators could avoid liability upon proof that they had transferred the waste to a treatment, storage or disposal facility, with a manifest providing presumptive evidence of that transfer.128/ The North Carolina scheme is a more limited no-fault liability proposal than the Congressional proposals. The North Carolina board carefully assessed the Superfund § 301(e) recommendations and then adopted those recommendations in part, while rejecting some of the Report's other proposals.

C. H.R. 2478 and H.R. 2867 - Toxic Compensation through the Back Door.

Before I leave the hazardous substance injury compensation legislative proposals, I should mention some other proposals, which I alluded to earlier, which would attempt to create a federal hazardous substance exposure cause of action through a route other than one of these "victim compensation" bills. H.R. 2867, the RCRA reauthorization bill, would authorize citizens to sue for damages from hazardous waste disposal in

---

128/ Michigan has already enacted a similar provision into law. Mich.Comp.Laws § 299.538.

Federal court by amending the citizen suit provision in RCRA. Former Assistant Attorney General Carol Dinkins has testified against this proposal because such counts would "unduly complicate, confuse, and delay" EPA and Justice enforcement efforts.129/ H.R. 2867 contains provisions allowing citizens to bring "enforcement" actions under an equivalent to RCRA's emergency hazard provision § 7003,130/ even where there are no alleged violations of a RCRA permit or any EPA order or regulation. In addition to making any overall EPA-Justice enforcement policy impossible for them to orchestrate, this provision could result in the transfer of much of the litigation that would otherwise take place in the state courts to the federal courts. In these "citizens suit" enforcement actions, the plaintiff is to be awarded attorneys' fees if he prevails.131/ Moreover, he could append his action for damages under state law to his RCRA suit under the doctrine of pendent jurisdiction.132/ Should he prevail on the pendent state claims, would

131/ H.R. 2867, 98th Cong., 1st Sess. § 11(b) (1983); H.R. 2478, 98th Cong., 1st Sess. § 12(e) (1983).

132/ See United Mine Workers v. Gibbs, 383 U.S. 715 (1966); see H.R. Rep. 98-198 (Part 1), 98th Cong., 1st Sess. 118-119 (1983).

his lawyer be entitled to a contingent fee on top of his court awarded fee? Even if state law were not promising or against him, a plaintiff could avail himself of the proposed expansion of § 7002 to cover past acts and to subject past offsite waste generators to § 7002 "injunctions."133/ In addition to reversing U.S. v. Wade134/ and U.S. v. Waste Industries,135/ H.R. 2867 would apparently provide plaintiffs with a right to order a remedy, such as to pay for a cleanup on someone else's property. The debate over the existence of a private right of action under the present Superfund Act would, in large measure, be mooted, since plaintiffs could seek to order cleanups in advance without incurring any costs initially or concerning themselves with possible inconsistency with the national contingency plan.136/

A second "back door" toxic substance compensation proposal is also hidden in H.R. 2867. Its innocuous looking Section 11(c) states: "Section 7002(f) of such Act is amended by striking out 'section' and substituting 'Act.'"137/ This

amendment to RCRA's savings clause is intended to "create" or "revive" a federal common law of nuisance which has been held to be superseded, to the extent existent, by Congress' enactment of the Clean Water Act, the Clean Air Act and RCRA.[138]

I believe that this attempted "revival" approach is ill-conceived for the following reasons.[139]

The Founding Fathers denied the federal government the *parens patriae* police powers of the British Crown, carefully safeguarding that residuum of sovereignty to the states. The common law of tort and nuisance is part of those retained police powers. This is the "true" common law in that it is the continuum of the pre-American Revolution English "judge-made" law. It was this true common law to which Justice Brandeis referred in the landmark case of *Erie Railroad Co.* v. *Tompkins*: "Congress has no power to declare substantive rules of common law, whether they be local in nature or 'general,' be they commercial law or part of the law of torts."[140]

[140] 304 U.S. 68, 78 (1937).

In Milwaukee I,141/ the Court did not abandon this fundamental concept that our federal government is a government of limited powers. Instead, it held that states had general access to the federal district courts to seek judicially-fashioned equitable remedies for interstate pollution where Congress has not by statute specified other federal forums. This right of access for federal judicial resolution of disputes between states which prior to the Constitution would have been an international controversy, was held to be an implicit quid pro quo for the original 13 states' ratification of the Constitution. This right was consistent with the express right accorded one state to sue another in the Supreme Court by Article III of the Constitution. Similarly, where Congress has not legislated the substantive standards which govern an interstate controversy between a state and another state (or person or entity outside the plaintiff state), the Court might consider state standards where they exist but the rule of decision necessarily is federal. These ad hoc, judicially-fashioned, equitable remedies for the states in the context of interstate pollution were referred to by the short-hand phrase "federal common law." But apart from this epigram, federal common law bore little relation to "state common law" other than that both were judicially defined rather than legislatively created.

141/ 406 U.S. 91 (1972).

In Milwaukee II,142/ the Court held that the Federal Water Pollution Control Act is now the fixed law which governs the rights of states regarding interstate water pollution controversies, leaving no room for judicial articulation of the "federal common law" to which the Milwaukee I court referred. In Middlesex County Sewerage Authority v. National Sea Clammers Association,143/ decided later in the Court's 1981 term, the Court held that no implied damages remedy exists under any federal law for violations of the Clean Water Act or the Marine Protection Research and Sanctuaries Act. The Court reasoned that because Congress had provided some express remedies in those Acts, "we are compelled to conclude that Congress provided precisely the remedies it considered appropriate."144/ Turning to the "federal common law" claim, the Court summarily dismissed it on the grounds that "federal common law" no longer existed, citing Milwaukee II.145/ Thus the question of whether private persons, as distinguished from states, ever had any standing to sue as plaintiffs under federal common law was moot. But in dicta on that issue the Court noted that the

---

142/ 451 U.S. 304 (1981).

143/ 453 U.S. 1 (1981).

144/ 453 U.S. at 15.

145/ 453 U.S. at 21-22.

Court of Appeals in Sea Clammers had gone "considerably beyond [Milwaukee I], which involved purely prospective relief sought by a state plaintiff,"[146] in asserting that federal common law could be invoked by private plaintiffs in an action for damages. Many observers believe that, had the Court reached and decided the moot question, it would have held that no private right of action ever existed because federal common law exists only for states.

Those who advocate creation or "revivification" of federal common law in the area of federal environmental law appear to ignore the fundamental distinction between state common law (the "true" common law in the sense of the continuing legacy of English common law) and the more restricted federal common law (an implied right of states to protect themselves derived from their entry into the Union). Moreover, the amendments to the savings clauses of the environmental statutes which they propose probably would not have their intended effect. I believe that the Court would hold a congressional attempt to delegate the formulation of a federal cause of action for damages to the federal courts unconstitutional on one or more of three grounds. First, private persons have no standing to assert a right of action under federal common law. Second, a congressional attempt to ape the House of Lords by "reversing" the Supreme Court's two decisions as if the court were the merely the Court of Criminal Appeal would violate the cardinal Constitutional principle of separation of legislative and judicial powers. Third, the attempt would also fall under the newly invigorated doctrine of standardless delegation.147/ If Congress desires to create a federal remedy to allow private persons to recover damages, it can do so only by legislating an express private federal cause of action.

[146] 453 U.S. at 10.

IV. A HUMBLE BEGINNING: FILLING SOME GAPS IN THE SUPERFUND ACT

I hope that this analysis of the various "Superfund" and "RCRA" hazardous substance injury compensation bills pending in the House against the background of our earlier Superfund Study Group deliberations will be be useful to you. I have also included as an attachment to this statement a table analyzing these and other pending bills.148/ Despite my criticisms of specific provisions in specific bills, I would like to emphasize that in my opinion substantial major reform is necessary in tort law generally, as well as in the laws applicable

---

147/ *See*, *e.g.*, S.Rep. No. 97-284, 97th Cong., 1st Sess. 164-165 (1981).

148/ Attachment B.

to injuries from hazardous wastes. In my view, the greatest chance for long lasting tort law reform in the hazardous wastes and other critical areas like products liability, asbestos and airline accidents lies in carefully selected and restrained federal preemption by Congress. Reform in all of these areas should be consistent unless there are articulated and impelling reasons for exceptions. Moreover, the extent and substance of federal preemption should, in my opinion, involve a careful balancing of what is best for the economy, what is the least disruptive of existing legal obligations, what is the proper additional burden to put on our federal courts and what is consistent with our federalism.149/ There has been no effort to date in Congress to see how reform proposals in these various fields of tort law relate to each other. It is not surprising that the optimum these reforms should take remains somewhat elusive at this point. "Quick fix" solutions (such as the creation of duplicative judicially-defined remedies in H.R. 2867) or of a federal cause of action deliberately left ill-defined (such as Section 107 of the Superfund Act) are not appropriate Congressional responses to this complicated problem.

This does not mean, however, that Congress should do nothing now in this entire area. The time for action clearly

---

149/ *See* my separate comments in the Section 301(e) Superfund Report at 307 and 328-329.

has arrived for it to correct some of the legislative mistakes made in 1980 in leaving many of the Superfund Act's cleanup liability provisions' most important features to so-called "common law development," that is to litigation with its associated unnecessary waste of both the government's and the private sector's resources. While Congress carefully considers meaningful long-term reforms of state tort law regarding identified hazardous substance injury problems such as asbestos and while it continues to search for the parameters of any hazardous waste exposure problem, it should move quickly to fill the gaps in the cleanup statute to prevent future exposure problems through cleanup now.

Let me suggest one modest example of such a gap filling, which would clarify the Superfund Act and make the cleanup program more workable. Congress would in my opinion substantially improve the Act by providing for explicit statutory joinder and apportionment rules for splitting the costs of remedial actions among liable defendants, as has been accomplished in the California and other state superfund laws. I have enclosed a first draft of such a "technical amendment" to Section 107 of the Superfund Act, along with an explanation, as Attachment E to this statement.

ATTACHMENT A

COMMENTS OF
GEORGE CLEMON FREEMAN, JR. [1]

I agree with some but not all of the recommendations in the Report.[2] There are also several important matters on which we spent considerable time that are not dealt with adequately in the Report. I address these matters in this separate statement.

1. Judge Breitel's Separate Views

Before turning to the Report, I commend the thoughtful comments of the most distinguished member of our Study Commission, Judge Charles Breitel of New York. I agree with Part II of his statement and his Conclusion. While I also agree with his general observations in Part I, I would like to make two comments.

First, after much thought, I do not put as much distance between myself and the Report. I participated in the give and take of its formulation and suggested substantive points and language changes. Some were adopted; others were rejected. The final Report, like the product of most committees, is incomplete, sometimes inconsistent, and sometimes deliberately silent or obscure. These flaws are usually unavoidable in the elusive quest for consensus. Despite the Report's weaknesses, it focuses on the crucial legal issues in the area of the generation, transport and disposal of hazardous wastes. But I agree with Judge Breitel that these issues need to be resolved with additional views outside the legal profession. As he points out, they merit consideration by a much broader community, including economists, businessmen, political scientists, and medical and scientific experts. Thus I join in urging that before Congress or the States act on any of the recommendations of this Report, they need to hear from these other disciplines, particularly the economists.

Second, I do not regard our decision to limit our focus as a default. It was a practical solution to the otherwise impossible problems posed by our deficiencies in time, personnel and perspective. Moreover, the reasonableness of our early decision to confine ourselves to what was feasible should also be viewed in light of how the Study Group was authorized. Section 301(e) of the Superfund Act was part of a political compromise. It was a substitute for specific provisions in the Senate Bill that would have created a limited Federal plenary action in tort for persons injured by many toxic substances. Opponents of the Senate bill's provisions voiced a number of concerns. Those concerns were addressed in two ways in the enacted legislation. First, the final Superfund Act was limited to provisions for the cleanup of spills and disposal of hazardous wastes. Second, the federal tort action provisions were deleted and our Study was mandated.[3] The remaining concerns were reflected in the charge given our Study Group by Section 301(e).[4] Our study, limited as is, addresses those issues. And in this context, it is significant that none of us thought that creation of a federal tort remedy was necessary or desirable.[5] Instead, we recommend a more limited Federal social insurance scheme, which would be far less disruptive of the economy and existing legal obligations, less burdensome on the Federal courts and more consistent with our Federalism.[6]

At the same time, I agree with Judge Breitel that a much broader reexamination of all the aspects of our legal system governing liability for all toxic substances is needed. Indeed, I would extend it to encompass other facets of "tort" law that also are in ferment: products liability, occupational diseases, automobile accidents and airline accidents. There are Constitutional and legal principles that are common to all of these areas of the law. These principles, as well as their application or nonapplication in any particular area, merit serious review. Any inconsistencies among these fields should be rational and deliberate, rather than the result of political accident, as happens all too frequently. Finally, the composite incidence of all these laws on our society -- the economic, political and other social effects -- needs to be assessed to see where change is needed and which changes would actually be in the public interest.

2. The Report's "Tier One" Recommendations.

A. "Orphan" Sites. -- I join in the recommendation of a limited social insurance system to aid persons who have been injured in the past through the disposal of hazardous wastes at sites that are now "abandoned" or "orphaned." State common law and most present State statutes provide no adequate remedy to compensate victims of improper disposal of hazardous substances at "orphan" sites. Since it is reasonable to assume that most of these wastes originated in past industrial activities in interstate commerce, it is also reasonable to assume that the country has benefited generally from the economic activities that generated them. From hindsight, we can see that improper disposal of these wastes in the past was in part attributable to the failure of our State governments to use their police powers adequately to control hazardous waste disposal or of our Federal Government to do so through its commerce power. Society as a whole should share some of these costs by providing compensation to those injured for actual injuries to health and for loss of wages which have not been compensated by other means. Since we are dealing with past conduct, the government, either at the State or Federal level, affords the only practical means of providing this limited compensation.

Because of the probable interstate commerce origin of these wastes and the Federal Government's greater taxing resources, when we discussed this matter last fall it appeared reasonable to recommend that the Federal Government fund this program. But since then several States have enacted or are considering State laws somewhat similar to our Tier One recommendation. California, for example, did so on September 25, 1981.[7] New York reportedly considered such a law this year.[8] If a substantial number of the States in which most of these orphan sites are located adopt appropriate legislation by the time Congress considers legislation along these lines, the practical need for Federal legislation dealing with orphan sites may have disappeared. In any event, Congress should take careful note of the States' ongoing efforts and take advantage of their experiences under their new statutes.

B. Existing and New Sites. -- I also join in the recommendation for creation of a Federal Tier One System to aid persons injured by hazardous wastes at ongoing or new disposal sites because it may be regarded properly as an incidence of Federal regulation of these sites under the Resource Conservation and Recovery Act (RCRA). Equally important, our current State tort systems generally do not provide a satisfactory means for dealing with relatively small claims whatever their origin.[9] Except where there are a number of similar small valid claims arising from the same situation that may be consolidated into a single trial, the expense of litigation often precludes recovery. Where the injury arises through the deliberate or negligent action of others, leaving the loss totally on the victim is obviously unfair. Also public awareness of this general deficiency of the present tort system may strengthen public opposition to socially needed or desirable economic activities in which the generation, transportation or disposal of hazardous wastes is unavoidable. Thus the creation of a social insurance compensation system would not only be fairer to those who are injured from hazardous wastes through no fault of their own, but also could lead to greater public acceptance of RCRA licensed hazardous waste management facilities that may be essential to our long term economic prosperity.[10]

C. The Limited Extent of Our Knowledge. -- I wish to emphasize that while I support the general concept of a Tier One system, subject to the reservations expressed below, I do not do so because I believe that there are many persons who have been injured by exposure to hazardous wastes and not compensated from other sources. Contrary statements in the Report have no basis in the information available to us. Repeated requests by the Group to the Justice Department for relevant "hard" evidence currently available to it and to EPA as to the extent of this problem produced very little.[11] Our Study Group had no practical means of remedying this lack of information since we were not constituted to be a fact-finding body. The Report correctly indicates the Group had no alternative but to conduct its Study on the assumption that substantial health problems caused by hazardous wastes exist and will occur. But statements to the effect that "some more evidence of hazard has become available" reflect neither a finding by the Group nor my personal view.[12]

D. Funding of a "Tier One" System. -- Based on the information available to the Study Group -- or, more accurately, the lack of information -- I cannot join in the Group's recommendation that the Tier One System be funded by a special tax on the chemical and oil industries, and perhaps other selected industries, rather than from general tax revenues.[13] The Study Group knows virtually nothing about the probable magnitude of direct costs of a Tier One system. Those costs would include funds paid to claimants and administrative costs.[14] Potential claims would include (a) those attributable to exposures to wastes disposed of prior to the enactment of any Tier One system and (b) those resulting from exposures to wastes disposed of after that date. The special tax the Study Group proposes would have to fund the total costs of "pre-enactment" disposal based claims, while subrogation would fund some of post-enactment based claims.

It is reasonable to suppose that most of the pre-enactment activities involving waste transportation or disposal were not licensed under RCRA, while virtually all of the post-enactment activities will be licensed.[15] Little is known about the actual nature, extent and location of hazardous wastes disposed of in the past across this country.[16] Also, virtually no information is available on the nature and extent of any personal injuries or property damage such wastes may have caused.[17] Turning to claims based on future activities, the potential costs of a Tier One system are also equally unpredictable. It is reasonable to suppose that the frequency of claims based on future disposal is more controllable because of the much greater care RCRA licensing will require. But there is always the problem that things viewed as harmless from today's knowledge may prove hazardous from tomorrow's hindsight. The only way to guard totally against the dangers of the currently unforeseeable consequences of economic activities is not to undertake them. But I do not see how anyone could seriously advocate society's prohibiting all activity that has not been proven to be "risk free."[18] The economic and political consequences of imposing a "risk free" standard of care on all economic activity would literally wreck our society.

The Parkinson's Law of bureaucratic programs insures that claims will be made and money spent under any government compensation system. If in such a system cancers which have multiple actual causes are presumed by law to have been caused solely or primarily by exposure to hazardous wastes, the potential for abuse is apparent. Thus while we could be confronting potential claims that aggregate only several millions, these claims might soar into billions.[19] Indeed, any dollar estimates of the costs of a Tier One system made in the near future may prove as erroneous as those made for the Black Lung Fund when it was amended in 1977.[20] The principal incidence of these unknown costs would fall, through the Tier One tax, on the chemical and oil industries. We have no idea what the economic effects would be on these industries and our economy.

In contrast, we know that our American economy is part of a world-wide economy, that many American industries are now being severely challenged by foreign producers and that our economy is in the midst of a severe recession.[21] The day-to-day livelihood, health and the security of our people depend upon the continuing ability of our domestic industries to compete successfully with foreign producers. This reality leads me to conclude that proponents of funding a "Tier One" system through increases in the current Superfund Act tax on specific American industries should have the heavy burden of proving that its incidence would not impede the ability of our domestic producers to compete with foreign producers in our own and foreign markets. If the ultimate result of this Group's proposals and other efforts to internalize the social costs of activities that produce hazardous wastes is to impair substantially that ability of our domestic industries to compete with foreign producers, then not only would these efforts at internalization fail, but also other direct and indirect external social costs would be visited on other citizens.[22] Those external costs could substantially exceed the external costs now being borne by others because of hazardous wastes disposal.

In summary, we must be careful in righting wrongs flowing from incomplete internalization of the social costs involved in the generation and disposal of hazardous wastes not to go overboard and impose a whole new set of non-internalized social costs -- loss of trade, unemployment, the disappearance of useful products -- that are equally capriciously and unfairly imposed on other segments of our society. Two wrongs can not make a right.

E. Statutory Presumptions. -- While I join in the Report's recommendation for a system to create "Toxic Substance Documents", I cannot support the particular statutory presumptions recommended.[23] Good presumptions can play a useful role in a Tier One system, just as good presumptions are an important part of the existing common law. But the statutory presumptions proposed here are not good presumptions.

The principal purpose of presumptions in the first tier ought to be to facilitate expedited payments to "qualified", or "worthy", recipients. They should be persons who have been injured primarily because of the hazardous wastes. Two secondary purposes should be to ease the burden on the administrators of the fund and to hold down overall transactional costs.

However worthy these three objectives, presumptions should be employed only where they are a valid reflection (a shorthand summary) of what is generally true. Since absolute truth is elusive in the areas we have considered, we should settle for the second best -- the prevailing views of the medical and scientific experts. But that is far better than the third best -- legislative fiats that reflect policy biases as to who should win rather than what is most likely to be objectively determined truth. One of the major problems with the three recently repealed Black Lung Act statutory presumptions was that they did not meet this criterion of truth, and they well nigh-wrecked that program.[24] Throughout the Study Group's deliberations Judge Breitel continued to remind us that in the common law the strengths of presumptions vary, and they vary directly in proportion to the reliability of their perceived nexus to the truth.[25]

Diseases such as cancers may have multiple causes. If the Group's two statutory presumptions are intended to make exposure to hazardous wastes the principal legal cause of such injuries and thus to lessen the importance of evidence of other causes, they cannot pass muster for the broad array of hazardous materials and diseases envisioned in the proposal. While these presumptions may well be valid for the rare form of cancer that is closely correlated statistically to asbestos inhalation, the strength of that single causal linkage appears to be exceptional. Cancer may often be the result of multiple factors acting together: heredity, diet, radiation exposures, climate, as well as what we breathe, eat and touch. One of the major problems with the implicit single cause criterion in the now repealed Black Lung Act presumptions was that they ignored this reality. What is called for in formulating reasonable presumptions in these multiple cause areas is probability analysis.[26]

The farther a presumption departs from reality, the more arbitrary it becomes. And the more dubious presumptions that are built into a statutory scheme, the more unfair it becomes.[27] The Supreme Court once said:

> [R]es judicata renders white that which is black, and straight that which is crooked... No other evidence can afford strength to the presumption of truth it creates, and no argument can detract from its legal efficacy.[28]

That should not be said of any presumptions written into any statute enacted pursuant to this report's recommendations or subsequently adopted under the administrative scheme recommended.

Turning to the recommended Toxic Substance Documents, if they are the product of a rigorous rulemaking process where scientific and medical peer group review of supporting studies and their underlying data is possible, then they can substantially aid in expediting recoveries and reducing transactional costs. Thus, preparation of these Documents should be entrusted only to an impartial federal agency, as distinguished from a "mission oriented" agency. The agency should also have no connection with funding of the Tier One system. The best scientific and medical evidence available should be assembled and tested through fair procedures where all concerned could have access and opportunity to participate. This would require going beyond the present bare bones notice and comment provision of the current Administrative Procedure Act to the "hybrid type" procedures that Senate Bill S. 1080, which was passed on March 24, 1982 by 94 to 0 vote, would afford.[29]

Documents produced through such a hybrid rulemaking process would be roughly equivalent to a scientific or medical treatise or journal article. Compiling and sorting the complex evidence in a single, generic proceeding would obviate the need for repetitious marshalling of the same evidence in case by case processing of multiple claims.

There is precedent for such an effort to expedite reasoned decision making in the experience of the Nuclear Regulatory Commission with hybrid rulemaking in dealing with complex generic issues. In the early 1970's the licensing of nuclear powerplants came to a literal standstill because generic health and safety issues under the Atomic Energy Act and generic National Environmental Policy Act issues were being adjudicated over and over again in individual plant licensing cases. The Commission finally broke the licensing impasse by removing each of these issues from those multiple forums and resolving it in a single generic rulemaking. Most commentators and courts applauded this process.[30]

Any discussion of presumptions must also take into account the reality that presumptions formulated for a Tier One system will eventually find their way by analogy into the Tier Two tort system. The Report recognizes that application of the proposed statutory presumptions would be grossly unfair if applied in Tier Two and seeks to avert this result by declaring that the "carryover" should not occur.[31] Such declarations are, however, likely to prove as ineffective as King Canute's order to the tide not to rise. In our Group discussions, Judge Breitel pointed out that legislative determinations are a source of common law principles. They will continue to be so however we opine. I believe that the better remedy to the perceived danger of abuses in Tier Two lies rather in greater restraint in the formulation of the presumptions for Tier One. If there were no statutory presumptions for Tier One and the only presumptions that were formulated administratively were factually sound ones developed through the deliberative process discussed above, it would be difficult to justify their rejection on either tier. There is little social merit in requiring the same factual matters to be relitigated time and time again.

F. Strict Liability. -- Judge Breitel in his comments points out that the analyses of "strict liability" adopted in the Report are flawed.[32] The Report's view is at the outer fringes, rather than in the mainstream, of current thinking on this aspect of the common law both in the courts and academia.[33] I disassociate myself from this aspect of the Report and instead concur in Judge Breitel's views.

G. Retroactivity. -- One topic that recurred again and again in our Group discussions was "retroactivity." Some of this discussion touched on the questions of Constitutionality, which an Appendix to the Report discusses,[34] but the bulk of it centered on questions of policy, which the Report does not discuss in sufficient detail.[35] This glossing over should not obscure one of the Study Group's most important decisions: the recommendation that subrogation for claims paid out of the Tier One system not apply to wastes disposed of prior to the enactment of any implementing legislation. Since I was one of the principal opponents of retroactivity, I believe it important to spell out the policy reasons for our opting against it.

Our discussion of retroactivity centered on the currently active hazardous waste disposal facilities. We decided to recommend imposition of liability for injuries or damages which were unforeseeable only on a prospective basis. Thus, the operator of an existing facility would have the option of staying in business under the new rule or closing it down. Concerns in the insurance industry, where "claims made" and "occurrences" policies still apply for differing sites, might also be lessened. As to past acts, the negligent operator would continue to be liable to the victim (or to those who compensated him) under common law principles, but the risk of unforeseeable injuries would rest on the Fund and not the operator.

In deciding against retroactive application of a "strict liability" subrogation claim, the Study Group looked to the same equitable principles which underlie the constitutional prohibition against ex post facto laws, due process and the general rule of construction that a statute should only be given prospective application.[36] We also recognized that sporadic imposition of strict liability on a retroactive basis poses potentially serious impediments to the long term availability of adequate insurance coverage at reasonable rates.[37]

H. Election of Remedies. -- On this issue, I join in the Anderson, Breitel, et al. statement and dissent from the Report's recommendation.[38]

I was one of the five members of the Group who voted to require a "binding" election between pursuing Tier One and Tier Two remedies. I understood that such a requirement would also have included a limited "safety valve" to avoid substantially unjust or unconscionable results. The proposal in the preceding joint separate statement, which was advanced after our final meeting in Boston on June 28, is an elaboration of that concept.

A limitation on election is needed to make a two tier system work. Relaxation of tort standards posed by (1) the statutory presumptions recommended in Tier One and (2) the Report's extreme views of strict liability if applied in Tier Two, might result in claims in both Tiers that would make predictability of economic risk impossible. Such predictability is needed by industry and insurers. Without that predictability the system would become increasingly costly and economically inefficient. It is also possible that insurance could become unavailable.

Thus, in setting any compensation schedules for Tier One, considerable care should be taken in setting ceilings on specified awards. The amounts of compensation available might have to be limited in rough relationship to the weakening of the causal connection resulting from adoption of the recommended statutory presumptions.

Concern over predictability also leads me to caution that great care should be taken in fashioning schedules for "the psychological, social and related injuries sustained ... geared to tangible events objectively identified as physical and neurological consequences of physical injuries." What is intended is to provide for schedules for specified physical injuries somewhat similar to those available in first party accidental injury policies. The underlined words have been carefully chosen to preclude payments for what is essentially the subjective component in "pain and suffering" awards. That component in its more exaggerated form becomes "punitive" or "exemplary" damages. But whatever it is called, the vengeance concept has no place in a Tier One system.[39]

I. Punitive Damages -- I also believe that punitive or exemplary damages have no socially desirable role in Tier Two when a comprehensive scheme of regulation such as RCRA, encompassing civil and criminal sanctions, is in place. I regret that my colleagues who were divided over this issue decided not to address it one way or the other in the Report. For my part, I believe that where Congress has exercised its commerce power to impose a comprehensive system of regulation over an industrial activity or practice and elects to leave private remedies to State law, it should nevertheless preempt any State punitive and exemplary damages since in essence they duplicate the criminal and civil sanctions provided in the

Federal statute.[40] Vigilantes have no place when the sheriff takes over. In my view, that duplication also constitutes an unreasonable burden on interstate commerce since it may furnish a major deterrent to engaging in worthwhile economic activity. A third reason is that unless class actions are to be required, permitting punitive damages to be imposed on activities regulated under RCRA might result in overcompensation of a few claimants and their lawyers to the detriment of many equally worthy claimants.[41]

3. Federal "Common Law" and Federal Implied Rights of Action

The Study Group received an inquiry from Senators Stafford and Randolph concerning the effect of two recent Supreme Court decisions, the *Milwaukee* and *Sea Clammers* cases on Federal common law in this area.[42] I agree with the conclusions in the Report that Federal common law no longer exists and when existent probably did not afford private parties, as distinguished from States, a right of action in the Federal courts.[43] In addition, I do not believe that Congress can constitutionally create or recreate a private right of action in common law through a "savings clause".[44] Congressional modifications of savings clauses in regulatory statutes, such as those recently considered in connection with S. 1716 and H.R. 6307,[45] would not change the substantive result in *Sea Clammers* or *United States* v. *Price*.[46] They would only serve to produce unnecessary confusion and litigation. It is also clear that the views expressed in one Congress about a prior Congress' intent (e.g., suggesting the Supreme Court's "misinterpretation" of that intent) are entitled to little weight because of the abuses apparent in post-hoc legislative history.[47]

4. Reexamination of the Current Tort System

Concern over social costs and their incidence leads me to emphasize the importance of the general call of the Study Group and Judge Breitel for a reexamination of certain fundamentals of our current tort system.[48] The thoughtful paper submitted to us by Richard Schmalz, which is summarized extensively in Part III-B of the Report, contains specific suggestions on how liability might be "channeled" in generating, transporting and disposing of hazardous wastes, following precedents in the nuclear field both in this country and in Western Europe.[49] His suggestions merit serious consideration and may prove to be one of the most important contributions to current thinking in this general area stimulated by our Study.

Serious questions exist as to whether our present tort system is operating at optimal efficiency, particularly where it requires duplicative insurance against virtually unlimited damages, coupled with ever increasing risks of liability based only on the most tenuous connection with the event actually causing injury.[50] Are looser and looser definitions of "strict liability" in the public interest?[51] Are efforts to extend the concept of "joint and several" liability to allocate costs to the "innocent" as well as the "guilty" in the public interest?[52] Are there fairer, more efficient, less costly alternatives for compensating persons for personal injury and property damage?

These fundamental questions as to the Tier Two tort system, which our recommendations would leave substantially intact and little changed, need to be raised and answered with regard to compensation for injuries and damages from hazardous wastes and the numerous other fields of tort law that are now in controversy.[53]

NOTES

1. Although I was one of the three members of the Study Group named by William Reece Smith, then President of the American Bar Association, I have participated in the work of the Group as an individual member of the bar and not as a representative of that association. I also wish to acknowledge the assistance given me by my associate, Alfred Light, and my research assistant, Karen Donegan, during this Study.

2. Like Judge Breitel, I do not vouch for any of the research papers that appear in the appendices. Some were furnished to us in the course of our deliberations, others only in the last few days of our efforts. Thus, I was able only to review drafts of several of them, which I commented on in letters which appear in the "Comments to the Appendices."

3. The compromise eliminated both a federal private cause of action and joint and several liability; added a third-party defense; eliminated all third-party compensation; and established a limit on compensation for each incident of damage to natural resources. 126 CONG. REC. S14,967-68 (daily ed. Nov. 24, 1980) (remarks of Sen. Stafford); *id*. at S15,004 (remarks of Sen. Helms); Grad, TREATISE ON ENVIRONMENTAL LAW §§ 4A.01(1)(f), 4A.05 at 4A-164); Report at 38; *see* 126 CONG. REC. S15,002 (daily ed. Nov. 24, 1980) (compromise superfund does not provide out-of-pocket medical expenses for individuals) (remarks of Sen. Williams); *id*. at S14,967 (compromise superfund eliminates virtually all third-party compensation, including payment of medical expenses to victims of waste releases) (remarks of Sen. Stafford); 38 CONG.Q.WEEKLY REP. 3435 (Nov. 29, 1980) (deletion of medical expenses "biggest concession" in compromise bill); *cf*. S.1480, 96th Cong., 2d Sess. (1980) (original Senate bill calling for strict liability private cause of action); S.Rep. 96-848, 96th Cong., 2d Sess. (1980); S.1486, 97th Cong., 1st Sess. (1981) (attempt to amend Superfund Act to include private cause of action previously rejected). The proposed provisions in S.1480 reflected some, but not all, of the provisions along the same lines in other bills in that and several other Congresses. *E.g.*, S.1483, 97th Cong., 1st Sess., (1981) (radiation exposure); H.R. 85,

97th Cong., 1st Sess. (1981) (oil spill damage); S.681, 97th Cong., 1st Sess. (1981) (oil spill damage). The Report explains the Study Group's rationale for limiting the study at pages 26-27.

4. *See, e.g.*, S.Rep. 96-848, 96th Cong., 1st Sess. 117-118 (1981) ("The [proposed Federal tort] system of liability . . . is unique and bizarre . . . The problems in such areas of civil procedure as res judicata, collateral estoppel, conflict of laws, and bar and merger have been wholly overlooked . . . [T]his federal alternative available as a partial remedy will seriously retard the development of the common law . . . [T]here has been very little demonstration made in the record as to the financial ability of the victim compensation fund to address the claims which will be honored . . . [T]he fee system is seriously deficient and inequitable.") (minority views of Sen. Simpson); *Id.*, at 119-122 ("S.1480 changes State tort law . . . [and] constitutes an intrusion into judicial processes . . . upon which industries and businesses have relied in assessing their exposure to liability and the availability of insurance . . . The definition of 'hazardous substance' is exceedingly broad . . . [A defendant] would find himself facing a barrage of suits in which he was being held strictly liable for all of the damages regardless of whether or not he had any control over the situation . . . [The bill] does not provide for apportionment in the case where a significant contributor who, for example, was responsible for 60% of damages must bear the full 100% of the costs because the other contributors cannot be found or identified or are found to be insolvent . . . The issue of applying the new standards retroactively remains a troubling one . . . [Subrogation would] shift the balance of litigation . . . [and the law would no longer represent] the drawing of an equitable balance between private litigants . . . . Consequently, it would appear that private sector decisions [would] have to be made [on basis of the worst case]: (1) the defendant faces litigation brought by the Federal government [by subrogation of private claims]; (2) he is one of a few or the single defendant in a case where the release was largely caused by another operator; (3) the more significant contributor is insolvent; (4) actions beyond his reasonable control caused the release; and (5) joint and several liability under S.1480 expose the defendant to the possibility of paying all the damages.") (minority views of Senators Domenici, Bentsen and Baker).

5. This rejection also took into consideration but rejected the arguments advanced in currant literature which called for such a remedy both before and after passage of CERCLA. E.g., Meyer, Compensating Hazardous Waste Victims: RCRA Insurance Regulations and a Not So "Super" Fund Act, 11 ENVIR.L. 689, 719 (1981); Sobel, A Proposal for the Administrative Compensation of Victims of Toxic Substance Pollution: A Model Act, 14 HARV.J.LEGIS. 683 (1977) (similar to Brodhead bill). Note, Inactive or Abandoned Hazardous Waste Disposal Sites: Coping with a Costly Past, 53 S.CAL.L.REV. 1709, 1745 (1980). The Study Group explicitly considered the S.1480 and Brodhead bill proposals and declined to recommend them. E.g., Report, at 215-218, 228-229, 238-239.

6. Younger v. Harris, 401 U.S. 37, 44-45 (1971) (Black, J.) ("[Continued adherence to the principle of Federalism encompasses] a notion of 'comity,' that is, a proper respect for state functions, a recognition of the fact that the entire country is made up of a Union of separate state governments, and a continuance of the belief that the National Government will fare best if the States and their institutions are left free to perform their separate functions in their separate ways. This, perhaps for lack of a better and clearer way to describe it, is referred to by many as "Our Federalism" and one familiar with the profound debates that ushered our Federal Constitution into existence is bound to respect those who remain loyal to the ideals and dreams of "our Federalism." The concept does not mean blind deference to "States' Rights" any more than it means centralization of control over every important issue in our National Government and its courts. The Framers rejected both these courses. What the concept does represent is a system in which there is sensitivity to the legitimate interests of both State and National Governments, and in which the National Government, anxious though it may be to vindicate and protect federal rights and federal interests, always endeavors to do so in ways that will not unduly interfere with the legitimate activities of the States."); see also Friendly, Federalism: A Forward, 86 YALE L.J. 1019 (1977). The Study Group discussed the possibility and potential unconstitutionality of mandating State implementation and administration of the proposed Tier One compensation system. But we noted that the Supreme Court "never has sanctioned explicitly a federal command to the States to promulgate and enforce laws and regulations." Federal

Energy Regulatory Commission v. Mississippi, No. 80-1749 (Jun. 1, 1982), *slip op.*, at 18. The Group opted instead for a "cooperative federalism" or partnership role between the two levels of government based on the model in the Federal Water Pollution Control Act, rather than a hierarchical model "antithetical to the values of federalism and inconsistent with our constitutional history." FERC v. Mississippi, *supra*, (O'Connor concurring and dissenting), *slip op.*, at 1. The national government should not be able "to force state governments to administer unpopular programs, thus transferring political liability for those programs to the States." FERC v. Mississippi, *supra* (O'Connor), *slip op.*, at 14n.19, *citing* Advisory Commission on Intergovernmental Relations, THE FEDERAL ROLE IN THE FEDERAL SYSTEM: THE DYNAMICS OF GROWTH, HEARING ON THE FEDERAL ROLE, p. 32 (October 1980) (statement of Daniel J. Elazar). *cf.* S.Rep. No. 97-151, 97th Cong., 1st Sess. 52 (1981) ("a policy . . . implicit in the institution of federalism created by the Constitution.").

7. CAL. HEALTH & SAFETY CODE, §§ 25370- 25382 (West 1981); *see* Report, at 66-67. I believe that an "orphan site" category includes (a) sites for which no solvent disposal site operator exists and (b) sites for which no other responsible party connected to the site *should* be held responsible. For example, landowners on whose property waste was disposed without their knowledge should not be responsible parties. *See* Report, at 244. Neither should present landowners who purchased property without reason to know the dangerous condition existing on the land. *See* Report, at 34-35.

8. N.Y. TIMES (Jun. 22, 1982), p. B.4. The state Superfund law New York enacted, however, does not provide for compensation of personal injuries. S. 10620 (July 2, 1982).

9. *See* Report, at 178-179.

10. These same factors were evident in the Reagan Administration's decision to promulgate compulsory financial responsibility requirements for licensed owners and operators of hazardous waste management facilities. 47 Fed. Reg. 16544, 16545 (Apr. 16, 1982) (to be codified at 40 C.F.R. Parts 123, 264 and 265). They also have been relevant in discussions at the International Institute for the Unification of Private Law (UNIDROIT) Committee of Governmental Experts, which

is preparing uniform rules for European nations relating to liability and compensation for damage caused during the carriage over land of hazardous substances.

11. Report, Part II; *see also* Grad letter to Assistant Attorney General Carol Dinkins, dated December 18, 1981, and Freeman letter to Chairman Zazzali, dated March 2, 1982 in the "Comments to the Appendices."

12. *See* Report, at 184. The Love Canal study released July 14, 1982 suggests that health problems related to that site may have been overstated. United States Environmental Protection Agency, ENVIRONMENTAL MONITORING AT LOVE CANAL, EPA-600/4-82-030a (May 1982). *See also* H.R.Rep. No. 96-IFC 31, 96th Cong., 1st Sess. 33 (1979) (concluding that early estimates of the number of waste sites were in error); Report, at 21n.19, 23n.34; one puzzling aspect of determining the extent of the abandoned waste site problem has been the suggestion that EPA is experiencing difficulty in finding sites appropriate for cleanup. *See EPA Expecting to Run Out of Sites to Clean Up, Expands Eligibility*, 13 ENVIR. REP. (BNA) 195 (Jun. 18, 1982).

13. The potential for abuse of the Tier One System remains even if the system were to be funded out of general tax revenues. However this potential is greater in the "special fund" situation because the periodic scrutiny incident to the annual budget and appropriations process is less rigorous in the case of special funds. Recent experience with the Federal Black Lung Benefits program and the New Jersey Spill Compensation Fund furnish examples. *See* Lopatto, *Amendments Fight Excesses of Black Lung Statute*, LEGAL TIMES (Mar. 22, 1982); *NJ Auditors Question Spill Fund Management Controls*, HAZARDOUS WASTE LIT. REP. 2,444 (May 18, 1982).

"Superfund" itself is controversial because funds have *not* been advanced to clean up abandoned hazardous waste dumps as expeditiously as Congress apparently intended. It has been charged that this delay has been attributable, in part, to EPA and the Justice Department's preoccupation with pursuing potentially responsible parties. *See* Baise & Bourdeau, *EPA's Implementation of the Superfund Response Program*, 3 ENVIR. ANALYST 3 (May 1982); *Administrative Delays Plague Cleanup Under Superfund, Indiana Congressman Says*, 13 ENVIR. REP. (BNA) 167 (Jun. 11, 1982); *cf*. 47

Fed. Reg. 20664, 20666 (May 13, 1982) (guidelines for using the imminent hazard, enforcement and emergency response authorities of Superfund and other statutes); EPA Guidance Memorandum on Establishing National Priorities List Under Superfund (Dated June 28, 1982), 13 ENVIR.REP. (BNA) 339, 341 (Jul. 2, 1982) ("EPA will consider Fund financed cleanup of [mining] sites only after all available enforcement efforts fail.").

Robert Hershey has reported more generally on rising criticism of the Federal Government's many insurance programs, which even without counting social security or unemployment insurance now cover more than $2,000 billion in risks. He quoted former OMB official Robert G. Penner, now at the American Enterprise Institute, as saying, "The real problem is the lack of careful scrutiny of these things." Hershey, U.S. Insurance; Critics Grow 131 N.Y. TIMES (Jun. 8, 1982), at 1, col. 2; 6, col. 1.

14. One major subcategory of administrative costs virtually overlooked in the Study Group's deliberations (see Report, at 231) are intergovernmental costs, the costs of assessing each State's prospective need for Tier One funds from the Federal Government and the timely periodic transfer of funds between the two levels of government. Because of (1) the proposed relaxation of liability (or "eligibility") requirements through the recommended statutory presumptions in Tier One, (2) the interpretation of "strict liability" advanced by the Report for Tier Two, and (3) because of the generous benefit levels recommended, the potential for the kind of "tragedy of the commons" which the social services block grant program (Title XX of the Social Security Act) experienced in the seventies exists. Derthick, UNCONTROLLABLE SPENDING FOR SOCIAL SERVICES (1977); Hardin, The Tragedy of the Commons, 162 SCIENCE 1243 (1968). This "tragedy" is that each State obviously has an incentive for maximizing its share of the funds, and in the absence of identifiable limiting principles on the group of eligible claimants and the consequent ability of the federal government to estimate need on a rough actuarial basis, the system's overall costs could well soar notwithstanding a modest need for the system to compensate injuries "actually" caused by hazardous wastes.

15. See Report, at 161, 230-232.

16. *See* Report, at 7, 10-11.

17. *See* Report, at 8-17; 24n.47.

18. *See* Leape, *Quantitative Risk Assessment in Regulation of Environmental Carcinogens*, 4 HARV.ENVIR.L.REV. 86, 107 (1980); Ricci and Molton, *Risk and Benefit in Environmental Law*, 214 SCIENCE 1096, 1099-1100 (1981).

19. The direct costs of the Tier One system would be substantially higher because the Group would allow recourse to the Tier One Fund at inactive waste dumps, even though a solvent responsible party is known, as well as at "orphan" sites. This contrasts with the Black Lung Act's compensation of miners only "when there is no responsible mine operator available to provide payments, when there is operator default and when the coal miner's last employment was before January 1, 1970." Baram, ALTERNATIVES TO REGULATION 216 (1982). I would limit compensation from the Fund at inactive sites to "orphan sites" as California did in its recently established state Superfund law. CAL. HEALTH & SAFETY CODE §§ 25370-25383 (West 1981). *See also* Report, at 66, 267n.94.

20. Claims under the Black Lung Benefits Act have exceeded substantially earlier estimated costs. *See* U.S. DEPARTMENT OF LABOR BRIEFING PACKAGE ON BLACK LUNG LEGISLATIVE PROPOSAL (1981). For example, in 1977, benefit outlays for 1978-81 were estimated to be $1,121,100,000. H.Rep. No. 95-151, 95th Cong., 2d.Sess. 27 (1978), *reprinted in* [1978] U.S. CODE CONG. & AD. NEWS 263. Actual expenditures proved to be $2,178,400,000 (a $1,057,300,000 difference.) 127 Cong. Rec. S. 15480 (Dec. 16, 1981). Black Lung benefit expenditures since 1969 stand at over $9 billion. HEARINGS BEFORE THE SUBCOMMITTEE ON OVERSIGHT OF THE COMMITTEE ON WAYS AND MEANS, HOUSE OF REPRESENTATIVES, 97th Cong., 1st Sess. 3 (1981) (Henig, Morton E.).

21. The timing of governmentally mandated expansions of industry costs could well be crucial to the prospect that the additional costs could be absorbed or passed on to consumers and thus internalized. Even where foreign competition is not a significant factor in the U.S. market, internalization is much less likely to occur when the economy is in a recession or depression. *See* Calabresi, *Some Thoughts on Risk Distribution and the Law of Torts*, 70 YALE L.J. 499, 520 (1961).

22. We should profit from our experience in other areas of environmental law. In some areas, such as automobile emissions controls under the Clean Air Act, we have been successful in internalizing pollution costs in the American submarket for automobiles because all cars sold within this country must meet the same emissions standard wherever they are manufactured. But efforts at internalization of pollution control costs have largely failed in U.S. submarkets such as steel, where foreign producers are not required to incur equivalent control costs. Tariffs are one means for offsetting otherwise discriminatory costs on our own industries, but they run counter to other national priorities. Even if tariffs were imposed for this purpose, they could provoke similar barriers to sale of American goods abroad. There are potential international forums for resolving these "internalization" dilemmas through negotiation. *See Legal Committee Completes Draft Covering Hazardous Substances Liability*, 5 INT'L ENVIR.REP. 182 (May 12, 1982) (United Nations Intergovernmental Maritime Consultative Organization); *OECD Waste Management Policy Group Plans Work on Export of Hazardous Waste*, 5 INT'L ENVIR.REP. 183 (May 12, 1982) (Organization for Economic Cooperation and Development). But as yet they are ineffective. A recent OECD report presented at the May 1982 Nairobi meeting on the global environment warned developing countries about the environmental aspects of their planned activities. "These countries are aiming at higher than average growth rates, their environmental machinery is incomplete, the backlog of pollution is large, and consequently the pressure on their relatively fragile environment is already severe." *Nairobi Meeting on Global Environment Looks at Progress Made in Past 10 Years*, 5 INT'L ENVIR.REP. 175 (May 12, 1982) (statement of James MacNeil, Director of OECD's Environment Directorate).

23. *See* Freeman letter to Grad, dated Feb. 19, 1982, in "Comments to the Appendices." In addition to believing that the recommended statutory presumptions in Recommendation Four [Report, at 198-199] are not sound policy here, I find their wording confusing. They represent a drastic modification of presumptions initially suggested by the Reporter [Appendix N, p. 314] which were rejected by the Group.

The Study Group modified the Reporter's suggested presumptions in two major ways. First, recognizing that diseases associated with hazardous waste exposure also may be associated with other causes, the Study Group substituted the words "contributed to" for "caused" in presumption (a) and voted to delete the word "solely" from presumption (b). Second, the Group decided to delete all references to a "person against whom a claim is made" in the statement of the presumptions and the showing which triggers them because it wished to eliminate the necessity for the claimant to identify a potential subrogee once he had identified the source of his exposure (i.e., the waste site or incident).

The presumptions as modified do not resolve the question of how strong a causal connection there should be between an industrial activity and an injury before the loss should be shifted to the Fund. Nor do they preclude the possibility that (a) the amount of a compensation award would be scaled in relation to the strength of the causal connection or (b) reduced if other contributory causes of the disease were present.

What do the modified presumptions actually accomplish? To benefit from either presumption, the claimant must prove by a preponderance of the evidence (1) the existence of a source which at the time of exposure was part of the hazardous waste system, (2) exposure to such hazardous waste, and (3) that the claimant suffered injury of the kind that is known to result from such exposure. Having made these showings, the first presumption that arises is that the waste contributed to his injury. Thus, the claimant is entitled to at least nominal damages unless the Fund rebuts the presumption, so long as the other eligibility criteria have been satisfied (e.g., a public collateral source has not compensated the claimant). The second presumption is more confusing. It states that the waste was responsible for the exposure and the resulting injury. The only reasonable explanation of this second presumption apparent in light of the modifications made to the earlier presumption drafts and the reasons for those modifications is that the Study Group wishes to place the burden of proof with respect to any contributory negligence defense the Fund might have on the Fund rather than the claimant. That is, as between the claimant and the Fund, the Fund bears the burden of proving that the claimant was responsible for the exposure and its consequences.

The Reporter cites the Workers' Compensation and Black Lung disease presumptions of compensability in his discussion of the Fourth Recommendation, indicating that they "serve the purpose of ruling out claimant's own physical weakness or habits as a contributory factor." [Report, at 203] This interpretation is, however, contrary to my reading of the presumptions and the meaning of the modifications made in them by the Study Group. In the Workers' Compensation and Black Lung situations, there are at least identifiable limited target populations, *i.e.*, employees or coal miners, although the Black Lung program has experienced considerable controversy over the revised statutory definition of "miner" which grew out of the 1972 and 1977 amendments to the Black Lung Act. Baram, ALTERNATIVES TO REGULATION 219 (1982) ("[Hazardous waste effects] are not effects that are confined to a narrow constituency like employees in a work place."); BLACK LUNG BENEFITS AND REVENUE AMENDMENTS OF 1981: HEARINGS ON S.1922 BEFORE THE SUBCOMM. ON LABOR OF THE COMM. OF LABOR & HUMAN RESOURCES, 97th Cong., 1st Sess. 119, 128-131 (1981) (statement of Frederick W. Webber). While it may be appropriate for employers to take care of employees who contract diseases which are sometimes but not always work-related, it is not appropriate to expect industry to provide such a service to non-employees. *See* *Diet, Alcohol, not Chemicals, Cited as Major Factors in Cancer Development*, 6 CHEM. REG. REP. (BNA) (Jun. 18, 1982); National Research Council, DIET, NUTRITION, AND CANCER (1982).

24. *See* Comptroller General of the United States, LEGISLATION ALLOWS BLACK LUNG BENEFITS TO BE AWARDED WITHOUT ADEQUATE EVIDENCE OF DISABILITY, HRD-80-81 (Jul. 29, 1981). In 1981, Congress repealed some of these presumptions, in a reflection of widespread dissatisfaction with the program. *See* 127 Cong. Rec. H. 9600-H. 9606 (Dec. 15, 1981); 127 Cong. Rec. S. 15474-S. 15498 (Dec. 16, 1981); 127 Cong. Rec. H. 9788-H. 9798 (Dec. 16, 1981); *see* Appendix to this statement.

25. He does so again in his Comments. *See* Breitel, at 6.

26. *Cf.* EPA's Proposed National Emission Standards for Hazardous Air Pollutants; Policy and Procedures for Identifying, Assessing, and Regulating Airborne Substances Posing a Risk of Cancer, 44 Fed. Reg. 58642 (Oct. 10, 1979); and Comments of the Utility Air Regulatory Group on the Proposed Regulations dated Feb.

21, 1981, in EPA Docket No. OAQPS-79-14. See also Rizzo & Arnold, Causal Apportionment in the Law of Torts: An Economic Theory 80 COLUM.L.REV. 1399, 1426 (1980) ("[C]ourts [are] becom[ing] increasingly aware of the merits of apportioning damages in tort . . . [and should be encouraged] to cast off their traditional reluctance to apportion damages among joint tortfeasors.").

27. See, Breitel, at 6; see also Note, Allocating the Costs of Hazardous Wastes Disposal, 94 HARV.L.REV. 584, 600 (1981) ("Alternatively, a rebuttable presumption of causation could be created in favor of plaintiffs in selected circumstances, with the result that responsible firms of the entire industry would be liable for costs greatly in excess of the demonstrated costs of the wastes. Such a system would be erratically punitive.").

Note that this multiple causation problem would not go away even if one were to eliminate subrogation and the retroactive aspects of a compensation plan completely. Non-subrogation simply shifts the ultimate incidence of a claim from an individual subrogee company to the taxpaying industries collectively. To the extent the taxpaying industries, even collectively, pay costs largely attributable to other causes of disease (e.g., the claimant's own habits, or his exposures to hazardous substances generated by non-taxpaying industries), the system distorts the marketplace for hazardous waste services and in effect creates a forced waste industry subsidy of other parts of society. See generally Stone, REGULATION AND ITS ALTERNATIVES 91-123 (1982); Klemme, The Enterprise Liability Theory of Torts, 47 U.COLO.L.REV. 153, 156-165 (1976). If the Tier One scheme through its presumptions and apportionment rules permits such distortions, then a special industry tax is completely inappropriate. The confusion evident in interpretation of what may be relatively innocuous presumptions in Recommendation Four confirms my view that both the funding and the presumptions recommendations are wrong. See note 23 supra.

28. Jeter v. Hewitt, 22 How. 345, 348, 63 U.S. 352 (1859).

29. See S.Rep. 97-284, 97th Cong., 1st Sess. (1981); cf. Admin. Conference of the United States, Recommendation 82-5, Federal Regulation of Cancer-Causing Chemicals (Jun. 18, 1981).

30. TO ESTABLISH A DEPARTMENT OF ENERGY AND NATURAL RESOURCES, ENERGY RESEARCH AND DEVELOPMENT ADMINISTRATION, AND A NUCLEAR SAFETY AND LICENSING COMMISSION: HEARINGS ON S.2135 AND S.2744 BEFORE THE SUBCOMM. ON REORGANIZATION, RESEARCH, AND INTERNATIONAL ORGANIZATIONS OF THE SENATE COMM. ON GOVERNMENT OPERATIONS, 93rd Cong., 2d Sess. 172, 195-211 (1974) (Statement of George Freeman); *see* Admin. Conference of the United States, Recommendation 82-5 (Jun. 18, 1982), at section V (generic rulemaking on cancer-causing chemicals); Gellhorn, *Public Participation in Administrative Proceedings*, 81 YALE L.J. 359 (1972); Comment, *Public Participation in Federal Administrative Proceedings*, 120 U.PA.L.REV. 702 (1972); Cramton, *A Comment on Trial-Type Hearings in Nuclear Power Plant Siting*, 58 VA.L.REV. 585 (1972); Cramton; *The Why, Where, and How of Broadened Public Participation in the Administrative Process*, 60 GEORGETOWN L.J. 525 (1972); Clagett, *Informal Action-Adjudication-Rulemaking: Some Recent Developments in Federal Administrative Law* 1971 DUKE L.J. 51 (1971); Murphy, *The National Environmental Policy Act and the Licensing Process: Environmentalist Magna Carta or Agency Coup de Grace?* 72 COLUM.L.REV. 963 (1972); Robinson, *The Making of Administrative Policy: Another Look at Rulemaking and Adjudication and Administrative Procedure Reform*, 118 U.PA.L.REV. 485 (1970).

31. Report, at 245, 248-250. Also, the Report is silent concerning whether the presumptions are to apply in the subrogation action. In my view, the proposed statutory presumptions should not since these particular presumptions are inappropriate in either Tier.

32. Breitel, at 4-5; *See* Freeman letter to Grad, dated March 10, 1982, in "Comments to the Appendices."

33. The Report's analysis [Report at 107-108] to the contrary notwithstanding, the New Jersey courts in *New Jersey v. Ventron Corp.* did not pronounce the sort of liability standard described in the Report for cleanup costs under the New Jersey Spill Control and Compensation Act. N.J.S.A. 58:10-23 *et seq.* (1977). The trial court noted in that case that "[i]n this case it was known by the liable defendants that mercury had dangerous potentialities." No. C-2996-75 (Super. Ct., Ch. Div. Bergen County, Aug. 22,1979), at 55; 1 CHEM & RADIATION LIT.REP., at 376 The appellate court in that case found that it could constitutionally apply the statute's liability standard retroactively because

the statute did *not* create a new "substantive liability." Instead, "[i]t was remedial only, providing a procedure for the imposition of costs to pay for the cleanup of prior *wrongful* discharges." 182 N.J. Super. 210 (App.Div. 1981) (emphasis added); *see* Report, at 150n.306. Furthermore, even when a statute appears to adopt an absolute liability standard making the defendant's knowledge or the objective foreseeability of an accident immaterial, foreseeability is still relevant on the issue of causation. The balancing of social costs and benefits of awarding compensation in a particular case at the expense of an industrial activity *always* takes place, at least implicitly, in a tort suit. Kuster, *Toxic Substance Contamination: The Risk-Benefit Approach to Causation Analysis*, 14 MICH.J.L.REFORM 53, 64-65 (1980) ("[P]olicy considerations are . . . manifest in courts' proximate cause determinations generally.").

34. Appendix L.

35. *See* Report at 161, 230-231, 234-235. In addition, I share Professor O'Connell's concern about the multiplicative number of proceedings arising out of the same incident. *See also* Professor O'Connell's separate statement. I would have substantially reduced the likelihood of repetitious proceedings by not only requiring in Tier One that notice be given to potential subrogees [Report at 231] but also by giving them a right, which is direct or indirect under most Workers' Compensation statutes, to participate in such proceedings.

36. U.S. Const., Art. I, § 9, cl. 3 (Congress forbidden to pass ex post facto laws); U.S. Const., Art. I, § 10, cl. 1 (state legislatures forbidden to pass ex post facto laws); the framers of the Constitution intended the clauses to apply to retroactive civil legislation as well as criminal legislation. *See* Crosskey, *The Ex Post Facto and Contract Clauses in the Federal Convention: A Note on the Editorial Ingenuity of James Madison*, 35 U.CHI.L.REV. 248 (1968); Field, *Ex Post Facto in the Constitution*, 20 MICH. L.REV. 315 (1922) but the clauses have been construed to apply *per se* only to criminal statutes. Calder v. Bull, 3 U.S. (3 Dall.) 386 (1798); the following state constitutional provisions prohibit all retroactive legislation: Colo. Const., Art. II, § 11; Ga. Const., Art. I, § 3(2); Idaho Const., Art. XI, § 12; Mo. Const., Art. I, § 13; N.H. Const., Art. I, § 23; Ohio Const., Art. II, § 28;

Tenn. Const., Art. I, § 20; Tex. Const., Art. I, § 16; *cf.* Murrill v. State Board of Accountancy, 97 Cal. App.2d 709, 218 P.2d 569 (1950) (retroactivity violated due process clause); Gayle v. Edwards, 261 Ala. 84, 72 So.2d 848 (1954) (state constitutional violation found in failure to disclose in title of legislation its retroactive effect); SUTHERLAND, STATUTORY CONSTRUCTION, §§ 41.02 - 42.12; Lundquist v. Coddington Bros., Inc., 202 F.Supp. 19 (W.D. Wis. 1962) (statute may not apply retroactively to revive a cause of action already barred by the statute of limitations); Haase v. Sawicki, 20 Wis.2d 308, 121 N.W.2d 876 (1963) (statute attempting to reinstate cause of action objectionable); Massey v. Sullivan County, 464 S.W. 2d 548 (Tenn. 1971) (statute abolishing rule of no contribution for joint tortfeasors cannot be applied retroactively). A law will not be construed as retroactive unless the act clearly, by express language or necessary implication, indicates that the legislature intended a retroactive application. United States v. Whyel, 28 F.2d 30 (3d Cir. 1928); Crawford v. Worth, 447 F.2d 738 (5th cir. 1971); First Nat. Bank in Billings v. First Bank Stock Corp., 197 F.Supp. 417 (D.Mont. 1961); Elliot v. Volpe, 328 F.Supp. 831 (D.Mass. 1971); Douglas Aircraft Co. v. Cranston, 58 Cal.2d 462, 24 Cal.Rptr. 851, 374 P.2d 819 (1962) ("a statute should be given the least retroactive effect that its language reasonably permits."); Mau v. Superior Court, etc., 101 Cal.App.3d 875, 881; 161 Cal.Rptr. 895, 898 (1980) (unfairness of retroactive application to insurers who relied on the previous law in setting premium rates).

Prospective only application of "strict liability" reflected a compromise between those Study Group members who advocated an "industry standard of care" standard for subrogation claims and those who advocated retroactive "strict liability." While the problem of parsing out injuries resulting from past disposal and injuries resulting from post-enactment disposal is difficult, those same difficulties exist under present law (*e.g.*, in determining when an accident occurs for purposes of insurance policy coverage).

37. *See* Report, at 161; Freeman letter to Superfund 301(e) Study Group, dated April 12, 1982, in "Comments to the Appendices;" U.S. Department of the Treasury, HAZARDOUS SUBSTANCE LIABILITY INSURANCE 81 (Mar. 1982).

38. *See* Separate Statement of Messrs. Anderson, Breitel, Freeman and O'Connell. *See also* comments on the Report by Messrs. Anderson, Breitel, Lundquist, O'Connell and Spannaus.

39. Strict liability, apportionment and damage issues are inextricably intertwined, as the Report sometimes fails to emphasize. For example, both the alternative liability and market share theories have been applied or considered only in cases involving *negligent* defendants. *Cf*. Report, at 49. Coupling either with recovery based on a theory of strict liability would go beyond current case law. Justice Traynor has recognized that strict liability situations are different. Limitations on damages, for example the exclusion of pain and suffering, are appropriate to prevent unfairness when liability is permitted without proof of fault. *See* Seffert v. Los Angeles Transit Lines, 56 Cal. 2d. 498, 511; 364 P.2d 337, 345; 15 Cal.Rptr. 161, 169 (1961) (Traynor, J. dissenting); and *see* O'Connell & Simon, PAYMENT FOR PAIN AND SUFFERING: WHO WANTS WHAT, WHEN AND WHY (1972); Levy & Ursin, *Tort Law in California: At the Crossroads*, 67 CALIF.L.REV. 497, 520-530 (1979).

40. *Cf*. Duke Power Co. v. Carolina Environmental Study Group, Inc. 438 U.S. 59, 84-94 (1977) (upholding Price-Anderson Act); Silkwood v. Kerr-McGee Corp., 667 F.2d 908, 922-923 (10th Cir. 1982) ("[P]unitive damages are 'awarded' against a person to punish him for his outrageous conduct and to deter him and others like him from similar conduct in the future.' *Restatement (Second) of Torts* § 908(1)(1979). *See also* City of Newport v. Fact Concerts, Inc., 453 U.S. 247, 266 (1981). . . [Thus where Congress has preempted the field of regulation of the nuclear industry, we are required] to hold invalid any state action that competes substantially with AEC (NRC) in its regulation of radiation hazards associated with plants handling nuclear material. A judicial award of exemplary damages under state law as punishment for bad practices involving exposure to radiation is no less intrusive than direct legislative acts of the state. Thus, we hold that punitive damages may not be awarded in this case.")

The intrusiveness of State punitive damages on the federal scheme of regulation is heightened where the Federal government requires the licensed persons to meet specified financial responsibility requirements, directly or through insurance. *e.g*. 42 U.S.C. § 6924(6) (1976) (RCRA); 42 U.S.C. § 9608 (1980) (CERCLA). Coverage against punitive damages is usually excluded from comprehensive general liability policies since as the Ninth Circuit recently noted "no rule of law limits the amount of punitive damages a jury may award." In re: Northern District of California "Dalkon Shield" IUD Products Liability Litigation No. 81-4648 et al, slip op. (Jun. 18, 1982). And intrusiveness into an intended uniform Federal scheme of regulation is compounded by the wide variations existing among the states as to when punitive damages may or may not be imposed. "[T]he 50 jurisdictions in which these [Dalkon Shield] cases arise do not apply the same punitive damages standards. Punitive damages standards can range from gross negligence to reckless disregard to various levels of willfullness and wantonness. Some states, in fact, do not allow punitive damages at all." Id.

Permitting punitive damages to be awarded in state tort actions for the same actions that are punishable by federal criminal and civil sanctions constitutes a form of double jeopardy -- multiple punishment for the same offense. While this multiple punishment does not violate the letter of the Double Jeopardy Clause of our Constitution, it is alien to its spirit.

41. See e.g. In re Northern District of California "Dalkon Shield" IUD Products Liability Litigation, 521 F.Supp. 1188, 1193 (1981), where the district court ordered certification of a nationwide class of all claims for punitive damages under FRCP 23(b)(1)(B) on two grounds. One was that:

> "It is clear that the amount of punitive damages sought far exceeds the available net worth of the company. This fact poses two very real threats if actions on this issue continue on an individual basis: 1) The company will be unable to respond to claims for punitive damages due to actual or constructive bankruptcy; or 2) At some point in the future, courts could rule that the aggregate sum alredy assessed against the defendant company in punitive damages was such that as a matter of law the company had been sufficiently punished and therefore punitive damage claims would be dismissed as a matter of law." 521 F.Supp. at 1193.

The Ninth Circuit Court of Appeals reversed on this point because:

> "The district court certified the 'limited fund' punitive damage class before requesting or receiving any evidence of Robins' net worth,

> earnings or available insurance coverage. After he ordered certification, the judge received Robins' attorney's affidavit showing the total claims against Robins and Robins' fund of assets but did not reopen discovery to permit plaintiffs to challenge these affidavits." No. 81-4648, *slip op*.

For a summary of the reasons for this overdeterrent effect, *see*, *e.g.*, Parnell, *Manufacturers of Toxic Substances: Tort Liability and Punitive Damages*, 17 FORUM 947, 965-967 (1982) ("Punitive damages, when considered in the setting of multiplaintiff litigation, are counterproductive. . .").

42. *See* letter from Senator Jennings Randolph and Senator Robert T. Stafford to Zazzali, dated April 29, 1982, in "Comments to the Appendices." City of Milwaukee v. Illinois, 451 U.S. 304 (1981); Middlesex County Severage Authority v. National Sea Clammers Association, 453 U.S. 1 (1981).

43. Report, at 70-75 and Appendix F. *See* Freeman letter to Grad dated December 16, 1981, and Freeman letter to Superfund 301(e) Study dated May 17, 1982 [with enclosure] in "Comments to the Appendices." *See* also Grad, TREATISE ON ENVIRONMENTAL LAW § 4A.05 at 4A-173 (Jun. 1982) ("[T]here is clearly no private right of action left under the federal common law of nuisance.") Even prior to 1981, when the Supreme Court made the matter only of academic interest, it was generally recognised that federal common law was "apparently confined to use by governmental entities . . ." Department of Justice, Land and Natural Resources Division, THE SUPERFUND CONCEPT: REPORT OF THE INTERAGENCY TASK FORCE ON COMPENSATION AND LIABILITY FOR RELEASES OF HAZARDOUS SUBSTANCES 16-17 (June 1979). The now defunct doctrine of the federal common law of tort or nuisance was predicated on concepts of State sovereignty and federalism, rather than individual rights, and therefore had no application to nongovernmental plaintiffs. *See* Comment, *Requiem for the Federal Common Law of Nuisance*, 11 ENVIR.L.REP. 10,191 (1981) ("The roots of the federal common law of nuisance reach back to the first decade of this century, when the Supreme Court for the first time acknowledged the jurisdiction of the federal courts to entertain cases brought by the States to abate pollution that has migrated across state lines . . . on the basis of rules borrowed from water apportionment cases and 'principles of federalism.'"); *cf*. In re

"Agent Orange" Product Liability Litigation, 635 F.2d 987 (2d Cir. 1980), *cert. denied sub nom.* Chapman v. Dow Chemical Co., No. 80-1882 (Dec. 14, 1981) (No federal common law tort liability for suppliers of "Agent Orange"). Milwaukee v. Illinois and Michigan held in 1981 that Congress' "establishment of a comprehensive regulatory program supervised by an expert administrative agency" supplanted the possibility of a federal common law available to State plaintiffs in water pollution cases. 451 U.S. at 317. Middlesex County Severage Authority v. National Sea Clammers Association therefore held that it was moot "whether [a] federal common law of nuisance could ever be the basis for a suit for damages by a private party." 453 U.S. at 11n.17. The lower courts have applied this rationale to hazardous waste cases, where RCRA and CERCLA provide the comprehensive statutory scheme which has supplanted any possible federal common law. United States v. Price, 523 F.Supp. 1055, 1069 (D.N.J. 1981) ("The comprehensive nature of the schemes established by the RCRA and the CERCLA require us to conclude that, if federal common law ever governed this type of activity, it has since been preempted by those statutes."); United States v. Kin-Buc, Inc., 532 F.Supp. 699 (D.N.J. 1981).

44. *See* Freeman letter to Orad, dated December 16, 1981, and Freeman letter to Superfund 301(e) Study Group dated May 17, 1982, [with enclosure]. *See also* Comment, *The Supreme Court Closes the Door on Implied Causes of Action Under Environmental Statutes; Middlesex County Severage Authority v. National Sea Clammers* 1 VA. J. NAT. RESOURCES L. 304, 326-327 (1981); Casenote, *Middlesex County Severage Authority v. National Sea Clammers Association; Implied Private Rights of Action for Damages Under the Federal Water Pollution Control Act Amendments of 1972*, 12 ENVIR.L. 197, 223-224 (1981); *cf.* S.Rep. No. 97-284, 97th Cong., 1st Sess. 164-165 (1981) (regulatory reform act).

45. *See* 127 Cong. Rec. S.12249 (daily ed. Oct. 27, 1981) ("technical" amendment to Clean Water Act in S.1716); H.R. Rep. No. 97-570, 97th Cong., 1st Sess. 21-22 (1982) (H.R. 6307, § 10).

46. 523 F.Supp. 1055 (D.N.J. 1981).

47. *E.g.*, Consumer Product Safety Commission v. GTE Sylvania, 447 U.S. 102, 118 (1980) (post hoc statement by conference committee entitled to little weight);

Waterman S.S. Corp. v. United States, 381 U.S. 252, 268-269 (1965) (legislative history of act passed long after another act does not afford any aid in interpreting earlier statute); Davies Warehouse Co. v. Bowles, 321 U.S. 144, 156 (1943) (suggesting post-hoc administrative interpretation of statute litigation inspired); Penn. Mut. L. Ins. Co. v. Lederer, 252 U.S. 523, 537 (1920) (no aid in construing an act of Congress can be derived from the legislative history of another passed six years later).

48. Report, at 240-256; Breitel at 9-10; In addition, even in the description of current law in the Report's Part III, time, budgeting and staff constraints obviously prevented the Group from completing the kind of comprehensive and thorough job typical of the Restatements. While the topics that are addressed in Part III of the Report are generally handled adequately, many other important legal matters were not addressed (*e.g.*, issues of contribution and indemnification, methods of apportionment such as comparative fault or comparative causation, legal defenses such as assumption of the risk and contributory negligence, and many insurance issues). More particularly, nothing in the Report should be construed to imply that hazardous waste companies under current law bear (or should bear), individually or collectively, the health or other social consequences of injuries or diseases to the extent those injuries or diseases are caused by others. Furthermore, where a better method of apportionment exists based on evidence in an individual case, joint and several apportionment may be inappropriate even though the burden of establishing the better apportionment method (*e.g.*, comparative fault, comparative contribution) might properly be placed on the liable defendants collectively rather than on the plaintiffs, according to the Study Group majority report. *Cf.* RESTATEMENT (SECOND) OF TORTS, § 433B(2) (1965) (burden of proof on apportionment); Report, at 69 (California "Superfund" apportionment rules).

49. Schmalz, *"Superfunds" and "Tort Law Reforms" -- Are They Insurable?* 38 BUS. LAW. (Nov. 1982 forthcoming); *see* Report, at 167-169; "claims-made" policies are not inconsistent with this approach, as the Report intimates; *see* Report, at 168, 176n.66. The Post-Closure Liability Trust Fund could be expanded to cover injuries arising out of accidents which occur during the operational life of a facility but which

manifest themselves only some time after closure and to cover those very few unexpectedly severe accidents whose damages exceed the high policy limits which would be required of facility operators under a "channeling" apportionment rule. *See generally* Light, *The "Long Tail" of Liability: Hazardous Waste Disposal Insurance and the Superfund Act's Post-Closure Liability Trust Fund*, VA.J.NAT.RESOURCES L. (1982 forthcoming).

REPORT AND RECOMMENDATIONS
ON LIABILITY ISSUES IN THE
AREA OF WASTE MANAGEMENT

Including

A Report on the Desirability
of Establishing by Statute
a Standard of Strict Liability

Prepared by

The
Governor's Waste Management Board

I. Introduction and Acknowledgements

The Waste Management Act of 1981 created the Governor's Waste Management Board to perform a number of functions relating to the safe management and disposal of hazardous wastes and low-level radioactive wastes in North Carolina. Among these mandated functions is the following:

> The Board shall study and make recommendations on policy issues including but not limited to liability and financial responsibilities within the waste management area. On or before January 1, 1983, the Board shall prepare and present to the Governor and General Assembly a report concerning the desirability of establishing by statute a standard of strict liability for persons involved in storage, transportation, treatment, or disposal of hazardous or low-level radioactive waste in North Carolina.

To carry out this mandate, the Waste Management Board referred the matter to its Legal Committee for study and recommendations. The Legal Committee is chaired by Charles Holt, former State Representative from Cumberland County. In addition to Representative Holt, the Committee is constituted of the two Board members who are members of the legal profession; Heman Clark, former Superior Court Judge and presently Secretary of the North Carolina Department of Crime Control and Public Safety, and William Graham, former member of the North Carolina Court of Appeals and presently Senior Vice President and General Counsel for Carolina Power and Light. The fourth member of the Committee is Melvin Hearn, Deputy Secretary of the North Carolina Department of Agriculture. Glenn Dunn, Attorney with the Solid and Hazardous Waste Management Branch of the North Carolina Department of Human Resources was the Staff Coordinator for the Committee's study.

The composition of the Committee brought an excellent combination of viewpoints to bear on a subject which demands a blend of policy considerations and technical understanding of a complex area of the law. The Committee requested and received valuable assistance from Robert Byrd, Professor of Torts and former Dean of the School of Law at the University of North Carolina at Chapel Hill.

In addition to Professor Byrd's assistance, the Committee benefitted greatly from the viewpoints and expertise of other persons or organizations. The Committee was fortunate to have had available to it since September 1982, a very thorough Report to Congress entitled Injuries and Damages from Hazardous Wastes - Analysis and Improvements of Legal Remedies. This Report is the culmination of a year-long study conducted by a carefully chosen group of lawyers with a variety of viewpoints and considerable expertise. One member of the group that produced the report was George C. Freeman, Jr., of Hunton and Williams, a law firm in Richmond, Virginia, with an extensive environmental law practice. Mr. Freeman, with considerable assistance from Alfred Light, also of the firm, donated much time and expertise to the efforts of the Legal Committee and attended several meetings.

With the aid of the above-mentioned persons and groups, the Committee reached its recommendations and presented them to the Waste Management Board at a public meeting held in Raleigh on December 1, 1982. Comments were received at that meeting from the following: John Runkle, Conservation Council of North Carolina; Dan Stroh, North Carolina Sierra Club; Wes Hart, North Carolina CATCH; and Cathy Markatos, Tri-County Alliance.

After considerable discussion, the Board accepted the recommendations set forth in the remainder of this report for presentation to the Governor and General Assembly. These recommendations were made only in regard to hazardous waste. The Governor's Waste Management Board will soon file a Supplemental Report addressing whether or not strict liability should apply to low-level radioactive waste.

II. Description of the Hazardous Waste Problem

The discussion of legal issues related to liability for injuries from hazardous wastes is necessarily hampered by inadequate factual and scientific knowledge. At this time it is impossible to determine the potential threat of personal injury and property damage posed by the various activities associated with hazardous waste, either in the nation as a whole or in North Carolina. Furthermore, the Board found itself handicapped by its incomplete understanding of what substances the full range of hazardous wastes includes and how hazardous those substances really are.

Despite this uncertainty, there is justified concern over the health consequences of transporting, treating, storing or disposing of hazardous waste. It is certain that the amount and variety of hazardous waste generated in our society is increasing at a tremendous rate. It is also certain that in the past some of this waste has been handled in an improper manner, particularly in areas of the country that became industrialized earlier than North Carolina. Fortunately, large chemical dumps, such as Love Canal, that have caused major environmental or health problems, did not accumulate in North Carolina twenty or thirty years ago.

Today, however, North Carolina has more than caught up with other parts of the nation in the generation of hazardous industrial by-products.

The textile, furniture, agricultural, paper, and chemical industries that are so important to this state all generate hazardous waste. North Carolina has been ranked eleventh in the nation in generating hazardous waste products. A survey indicates that North Carolina has approximately 700 major hazardous waste generators - i.e. generators that produce more than 2,200 pounds of hazardous waste per month. There are approximately 250 facilities that treat, store or dispose of hazardous waste in this state.

North Carolina also has suffered in recent times from improper disposal of waste such as the illegal dumping of PCB laden oil along more than two hundred miles of roadside.

Despite the increasing problems, this state still has suffered relatively little damage from hazardous waste up to this time. Furthermore, the swift and thorough implementation of a hazardous waste regulatory program should substantially reduce the probability of improper waste handling practices. North Carolina has been among the first states to gain authorization to implement the hazardous waste regulations adopted under the Federal Resource Conservation and Recovery Act (RCRA). The regulations require a "manifest" or tracking system which documents the kind and amount of waste produced by a generator and traces the waste until it is properly rendered non-hazardous or disposed of. The regulations also establish standards for design and performance to be followed in the packaging, transportation, treatment, storage and disposal of hazardous waste. And, of particular importance to the subject of liability for injuries, treatment, storage and disposal facilities are required to carry liability insurance of at least $1,000,000 per incident and $2,000,000 annual aggregate for sudden occurrences, and $3,000,000 per incident and $6,000,000 annual aggregate for non-sudden occurrences.

Despite the safeguards provided by the regulatory program, there is still general public skepticism concerning the safeness of hazardous waste management facilities - a skepticism that crystalizes into awesome resistance in any local area where a facility is proposed. Such resistance has thwarted establishment of many needed facilities nationally, and has been equally as apparent in North Carolina in the vehement local opposition to treatment facilities proposed in Mecklenburg and Guilford counties, and to landfill facilities proposed in Warren and Anson counties.

Yet these facilities are needed. As the General Assembly declared in the Waste Management Act of 1981, the safe management of hazardous wastes, and particularly the timely establishment of adequate facilities for the disposal and management of hazardous wastes are essential to the economic growth and to the public health and safety in North Carolina.

In its deliberations concerning liability issues related to hazardous waste, the Board was compelled by the belief that one of the most important considerations in public acceptance of the necessary waste management facilities in North Carolina is the assurance that persons harmed by the generation, transportation, storage, treatment, and disposal of hazardous waste will be fairly compensated. This realization is supplemented by the conviction that it is more just that the cost of injuries caused by hazardous waste be borne by the handler of the waste rather than the injured person. The costs of compensating for such injuries can be passed on by the handler and reflected in the cost of the service or product he provides. However, it is important that there be some limits to liability; otherwise necessary waste management activities would become uninsurable or, at the very least, the cost of liability insurance would be prohibitively high.

Under the present common law, recovery for injuries caused by hazardous wastes is very difficult for several reasons. The effects of hazardous waste on people and the environment are often subtle and may be delayed for many years. This long latency period makes it difficult for an injured person to trace the cause of the injury, and indeed often acts as an absolute bar to recovery if the statute of limitations has run or the potential defendant has vanished.

The effects of hazardous chemicals are often uncertain and affected by many factors and intervening causes. Proving that a waste caused a particular injury is a highly technical matter requiring expert witnesses and other very expensive technical assistance. Requiring an injured person to prove that the waste was handled negligently as a prerequisite to recovery creates additional difficulty and expense. Indeed, proof of negligence may be impossible when the dangers of the waste are unknown, or when the waste combines with other substances or circumstances to cause injury. In either case the particular injury may be considered unforseeable so that the injured party would be denied compensation. The effect of these difficulties and expenses is that some claims, particularly smaller ones, go uncompensated, often because they are too expensive to pursue.

The justness and political necessity of assuring fair compensation for injuries, combined with the barriers to such compensation under existing tort law, convinced the Board that certain liability reforms should be made by statute. Although case law may be moving in the direction of some of the needed reforms, the progress is uneven and unpredictable. Statutory reforms can add predictability to liability decisions which should be to the advantage of hazardous waste handlers and their insurers, as well as injured persons.

In recommending these reforms, the Board realizes that the existing RCRA definition of regulated hazardous waste may be overly broad and includes some wastes that may not be hazardous enough to justify the recommended liability reforms. Nevertheless, in an effort to ensure a liability system that blends with and complements the ongoing regulatory program, it is recommended that hazardous waste be defined as it is under the state RCRA program. Use of this definition ensures that hazardous waste generators, transporters, treaters, storers and disposers will be easily identifiable and on notice that they are subject to any recommended statutory reforms enacted by the General Assembly.

III. Recommendations

A. Application of Strict Liability for Injuries Caused by Hazardous Waste

RECOMMENDATION 1 -- The Board recommends that strict liability be applied by statute to any generator, transporter, treater, storer, or disposer of hazardous waste in control of the waste at the time it causes injury to a claimant, and that strict liability on the part of a generator continue while the waste is transported and until it is accepted by a properly licensed treatment, storage, or disposal facility.

There seems to be a growing consensus that the common law tort system, based on negligence, fails in ensuring that meritorious small and multiple claims for damage are compensated. This is especially true in highly technical areas such as "toxic torts." The reason for this failure is the high cost of litigation necessary in order to prove negligence, such as expensive expert witnesses and high legal fees for protracted negotiation and litigation. These high "transactional costs" have resulted in a burden on the court system, higher insurance costs, and a reduced percentage of the recovery going to the injured party. Strict liability is seen as a way to reduce these costs and to ensure that injuries are compensated by removing the barrier to plaintiffs of having to prove negligence.

Indeed, common law has long acknowledged that certain activities are so hazardous that no degree of care on the part of the actor is adequate to prevent possible injuries. Persons who engage in such activities are held strictly liable for injuries they cause, and the injured party therefore is not required to prove negligence to be compensated.

Opponents of strict liability claim that it is unfair to hold a person responsible for damages when that person has conducted his activities (in this case, the handling of hazardous waste) in a safe, non-negligent manner. They contend that such an approach will discourage useful economic activity or, at the very least, raise insurance costs substantially. The response to these objections is generally that it is more unfair to leave an injured person uncompensated, and that higher insurance costs will be reflected in an increased cost of conducting the activity -- a cost that reflects the true social costs of the activity.

The range of activities to which strict liability should apply was an important issue for the Board to decide. For regulatory purposes, hazardous waste handling activities are divided into generation, transportation, treatment, storage or disposal. The most comprehensive alternative is to impose strict liability for all of those activities. The RCRA regulatory program, however, distinguishes between hazardous waste generators and hazardous waste management facilities, i.e., treatment, storage and disposal facilities. Generators are not as strictly regulated and are not required to carry liability insurance. Treatment, storage and disposal facilities are heavily regulated because the constant presence of large volumes of waste presumably increases the risk they pose, whereas generators must remove any waste they generate within 90 days. It is particularly important to note that treatment, storage and disposal facilities are required to carry liability insurance in the amounts mentioned on page 4 of this report.

In North Carolina, there are approximately 700 large generators of hazardous waste and many more small generators. There are approximately 250 hazardous waste management facilities, over 225 of which are also generators.

Numerous transporters are involved in transporting hazardous waste. Transporting waste probably exposes more people to risk than any other aspect of handling, although statistics show that accidents are rare. While hazardous waste transporters are subject to relatively strict regulatory requirements imposed both by the Environmental Protection Agency and the Department of Transportation, these requirements do not include mandatory liability insurance. Transporters typically require that shippers or receivers indemnify them for accidents occurring during transport resulting from the hazardous nature of the material transported.

Another key issue is the apportionment of liability among the various activities involved in handling hazardous waste. Existing North Carolina law imposes joint and several liability on defendants whose conduct combines to cause an indivisible injury. Under joint and several liability, a single defendant who makes a substantial contribution to the damage is liable for the entire amount of damages. In order to get complete compensation, a plaintiff has to find and prove liability on the part of only one defendant. That defendant, upon payment of the plaintiff's claim, may seek contribution from any other responsible parties.

Joint and several liability is subject to two related criticisms in the hazardous waste context. One is that it is unjust to hold a person who handles a waste liable for any and all damages when he may have acted more carefully than the other parties involved. The other is that insurance costs will become extremely high if every party in the chain of handling the waste has potential liability for all damages, especially if a strict liability standard is in effect.

The Board's recommendation reflects its conclusion that strict liability will help ensure that one of the barriers to meritorious claims, particularly smaller claims, is removed. Strict liability should also cause handlers of hazardous waste to use the greatest possible care to employ practices that minimize the risk of injury.

Continuing generator liability through the transport stage, a limited application of joint and several liability, helps prevent large claims for damages caused by waste in transport from going uncompensated because the transporter, who is not required to carry a certain minimum amount of liability insurance, has inadequate assets or insurance. On the other hand, under the recommended approach, a generator's strict liability does not continue indefinitely because it is terminated when the waste is accepted at a permitted and regulated treatment, storage, or disposal facility. Unlike transporters, facility operators are required under RCRA to carry liability insurance, and it is therefore less likely that they will be unable to compensate for damages.

Under the recommendation, apportionment of damages where strict liability is imposed would be as follows: a person injured by a waste under control of a generator would seek recovery only from the generator under a standard of strict liability; a person injured by waste in the transport stage could seek recovery from the transporter in control of the waste at the time it caused the injury, from the generator, or from both because they would be jointly and severally liable under a standard of strict liability; a person injured by waste at a treatment, storage, or disposal facility could seek recovery only against the owner or operator of the facility under a standard of strict liability.

The recommendation can be implemented by providing by statute that the person in control of a waste shall be strictly liable for damages caused by that waste; and furthermore, a generator of a hazardous waste shall be strictly liable for any damages caused by that waste, except that it shall be an absolute defense if the generator can show that the waste has been properly delivered to and accepted by a treatment, storage and disposal facility properly permitted to receive the waste.

The recommendation blends well with the regulatory program which, among other things, requires that a generator prepare and keep a written "manifest" for any waste shipped by him. The statute could provide that the manifest gives rise to a presumption that the waste was shipped to and accepted by a permitted facility. This presumption would encourage generators to comply with the manifest system.

RECOMMENDATION 2 -- The Board recommends that strict liability apply only to active facilities and ongoing activities.

Although inactive facilities and abandoned sites have substantial potential to cause injuries, a statutory framework already exists at both the federal level (the so-called "Superfund" law) and the state level (the Oil and Hazardous Substances Pollution Control Act) to deal with these spills. Both laws authorize a fund to be used to clean up spills and restore damaged resources. The State statute also establishes a standard of no-fault (strict) liability for damages to persons or property resulting from a discharge into state waters, which would apply in many cases involving damages due to discharges from abandoned sites. While the present Superfund framework does not provide for recovery of personal injury or private property damages, Congress will consider next year a victim compensation scheme recommended by the study group established by Section 301(e) of that law.

The Board was also concerned that imposing strict liability for past acts raises potential constitutional problems and that insurance policies generally covering those acts might not apply to liability that did not exist when the acts took place.

The recommendation reflects the Board's conclusion that existing statutes requiring responsible parties to clean up inactive facilities should be given a chance to succeed in minimizing potential injuries. It is at best harsh, and at worst unconstitutional, to apply statutorily a standard of strict liability for injuries caused by past acts. In such cases the appropriate common law standard should apply.

RECOMMENDATION 3 -- **The Board recommends that strict liability apply only for injuries resulting from risks associated with the characteristics that make the waste hazardous.**

There is no justification for applying strict liability for injuries caused by the normal activities of a hazardous waste handler if those injuries are not caused by the waste itself. It is, after all, the hazardous nature of the waste that justifies application of strict liability.

The following is a somewhat exaggerated application of this recommendation. A worker at a hazardous waste facility runs over a drum lying near the property boundary and sends some fragments of metal flying that injure a bystander. This injury results from an activity associated with hazardous waste management, but does not relate to the characteristics that make the waste hazardous, and therefore, strict liability would not be imposed. However, if it were a corrosive hazardous waste that squirted from the drum and burned the bystander, the injury would result from the hazardous characteristic of the waste, and strict liability would be imposed.

RECOMMENDATION 4 -- **The Board recommends that a handler of hazardous waste be held strictly liable for all injuries caused by the waste, regardless of whether he knew at the time of injury that the waste could cause that particular type of injury.**

The view that liability should exist for all injuries caused by the waste is supported by the argument that it is better that the person that causes the injury pay for it than the innocent victim. On the other hand, the deterrent value of such a policy is questionable because a person can only take precautions against unknown risks by not acting at all. Such forbearance of action can certainly slow economic and technological progress.

The recommendation is consistent with the goal of emphasizing compensation regardless of fault. The Board emphasizes that this does not mean that strict liability will be applied retroactively in the case of a waste that was not considered hazardous at the time of the act that caused the injury. It only applied to an unknown effect from a waste known to be hazardous at the time it causes the injury.

RECOMMENDATION 5 -- The Board recommends that strict liability apply to successors in interest as well as to the generator, transporter, treater, storer or disposer in control of the waste at the time it causes the injury.

To impose liability to successors in interest has the effect of increasing the parties from whom compensation might be sought, thus increasing the possibility that an injured person will be compensated. The former owner of a facility, for instance, should not, by selling the property, be able to relieve himself of liability for injuries caused by conditions he created.

This recommendation would help avoid cases where an injured person is unable to recover damages because the company that created the hazard has passed out of existence or sold a site with a latent hazardous waste problem to another person. In such cases, the new owner may be the only person able to compensate the injured person. Owners of facilities are required to record on the deed that the site has been used as a hazardous waste facility. Therefore, subsequent purchasers should be on notice and have full opportunity to assess the risks they may be acquiring.

RECOMMENDATION 6 -- The Board recommends that punitive damages not be allowed for claims where strict liability is applied.

Damages in tort claims can be generally categorized as compensatory damages such as medical bills, lost property value, lost wages, pain and suffering, mental anguish or similar intangible injuries; and punitive or exemplary damages. The first category focuses on compensating the injured person, but the second focuses on punishing the liable person. Punitive damages are awarded only if the defendant's conduct which causes the damage is intentional, reckless, or in wanton disregard of the safety of others.

The justification for punitive damages is questionable for activities such as waste management that are regulated by a comprehensive statutory scheme which includes criminal and civil penalties for violations of such regulations. Such regulations set the standards for the regulated activities, and the statutory penalties should be considered the exclusive means for punishing violators.

Another reason for not allowing punitive damages is that large punitive damage awards made to initial claimants may leave inadequate funds (or insurance) to compensate others who are injured. Such a possibility becomes more likely when multiple claims arise from the same action. The resulting exhaustion of funds is incompatible with the goal of ensuring that as many injured parties as possible are compensated for their actual injuries.

On the other hand, it is argued that regulatory programs generally are not adequately enforced and penalties are not large enough to deter reprehensible waste management practices, and therefore, the threat of punitive damages is a necessary additional deterrent. However, citizen suit provisions under federal and state statutes permit private initiation of enforcement activities in some cases.

The Board concluded that disallowing punitive damages is consistent with the goal of compensating claimants for injuries without consideration of fault on the part of the defendant, and may help avoid extremely large recoveries based on punitive damages that render a defendant financially unable to compensate other injured persons. Sufficient remedies are provided by state and federal statutes in the form of criminal and administrative penalties for violations by hazardous waste handlers.

RECOMMENDATION 7 -- The Board recommends that although strict liability is imposed, contributory negligence of a claimant will bar any recovery by that claimant.

Under negligence law, a claimant cannot recover damages if his own negligent acts contribute to his injury. However, where strict liability is imposed, recovery is not prevented by ordinary contributory negligence, but will be prevented if the claimant voluntarily and knowingly exposed himself to the risk. The Board concluded that an injured person should not be able to recover, even where strict liability is imposed, if his own negligent acts are an essential cause of the injury.

B. Statute of Limitations

RECOMMENDATION 8 -- The Board recommends that the statute of limitations begin to run only when the injury becomes apparent or ought to become apparent to an injured person, and that the ten-year statute of repose not apply.

The purposes of statutes of limitations are practical ones: (1) to ensure that legal actions are not initiated so long after the time of the acts alleged to have caused the damage that the facts necessary to litigating the matter have "grown cold" (i.e., are no longer capable of accurate determination), and (2) to ensure that persons are not subjected indefinitely to the threat of liability for past actions.

When strict liability is applied, the first reason becomes less important because there is no need to recall facts relevant to whether the defendant's acts were negligent. The main issue of fact becomes whether the hazardous waste under the control of the defendant caused the injury, an issue based more on scientific data than on facts relating to the defendant's actions. Furthermore, statutes of limitations have no deterrent value and in the case of injuries with long latency periods, they provide a shield for waste handlers.

Commencement of the running of the statute of limitations at the time of the defendant's act can be an unfair barrier to recovery for injuries caused by hazardous wastes. Many of the effects of chemical wastes may not manifest themselves for many years. This same problem exists in relation to many other types of injuries in our society today. The fairness of statutes of limitation that run from the time of the act of the defendant has been challenged and most states have statutes that run from the time of "discovery" of the injury by the injured party.

North Carolina's statute [N.C.G.S. 1-52(16)] presently provides that an action must be brought within 3 years "from the time that the injury or damage becomes apparent or ought reasonably to have become apparent to the claimant," but then provides an absolute bar, known as a statute of repose, against any action brought "more than 10 years from the last act or omission of the defendant giving rise to the cause of action." Thus, in North Carolina an injured party has three years after the discovery of the injury in which to initiate an action for recovery; however, no action may be brought after ten years under any circumstances.

The goal of facilitating compensation of injured persons outweighs the practical advantages of putting potential legal actions to rest after a certain period of time. This is especially important in cases where the condition causing the damage may develop very slowly (for example, a buried toxic waste may take many years to reach adjacent water supplies) and where the injury from the condition may not manifest itself for many more years.

C. Causation and Related Evidentiary Requirements

RECOMMENDATION 9 -- The Board recommends that there be no attempt to ease the plaintiff's burden of proving that the injury or damage was caused by the hazardous waste handling activity of the defendant.

As the law presently stands, a plaintiff must prove in each case that there is a causal connection between the disease or injury complained of and the hazardous waste related activity of the defendant. Proof of this causal connection is usually difficult in these cases for several reasons.

First, a plaintiff must show the nature of the exposure - whether by inhalation, ingestion or other contact - in order to show the duration, frequency and intensity of exposure. If exposure is adequately proven, proof of causation will usually require large amounts of sophisticated and thus very expensive, medical and scientific testimony to demonstrate the epidemiologic or statistical correlation between the hazardous waste(s) in question and the injury or disease.

Additional problems of proof stem from the fact that there is often a long latency period before effects of exposure become obvious, and during that period the injured party may have been exposed to a wide variety of substances from other sources. Furthermore, a facility alleged to cause the injury may have handled many types of waste which may interact to cause effects that none of them would cause alone, making it more difficult to determine the exact cause of the injury.

Finally, medical science has simply not been able to determine the effects of many chemicals already on the market and, of course, even less will be known at any given time concerning the effects of new chemicals that enter the market constantly.

The difficulties in proving causation have been eased in Workers Compensation Laws by a "rebuttable presumption" approach.

Under this approach, if the plaintiff can prove that he suffers from certain types of injuries and that he has had a certain amount of exposure to the substance in question that is known to cause those injuries, the burden shifts to the defendant to prove that the substances within his control did not cause the injury.

This "rebuttable presumption" approach is considered fair because a substantial body of information exists concerning certain substances (for example, asbestos) to show a strong statistical correlation between exposure to the substance and the subsequent development of certain diseases [for example, in the case of asbestos, mesothelioma (lung cancer)]. This is particularly valid and useful in worker's compensation cases because employees are exposed day-in and day-out to a known set of substances.

However, in the case of injuries allegedly stemming from hazardous wastes, the plaintiff will less often be subject to constant exposure over a long period of time and the exposure is likely to be to a greater variety of substances or, for that matter, many unknown substances. This should become even more the case now that strict regulatory programs are in effect which tend to isolate the waste in closely controlled facilities. Thus a presumption of causation in the case of alleged injuries from hazardous waste is probably not as valid or fair as in workplace injury cases. Even in the workplace injury context, however, there have been abuses. For example, Congress in 1981, felt it necessary to abolish several statutory "rebuttable presumptions" in the Black Lung Benefits program because many successful claimants under the program did not have adequate medical evidence of black lung disease.

There is at present insufficient indication that there will be a large number of cases alleging injuries from similar types of wastes, which is the circumstance that justifies a presumption of causation. At present, it seems likely that claims for injuries will involve a wide variety of wastes, and that causation must be verified on a case-by-case basis.

D. Administrative Mechanisms for Determining Liability and Compensating Injured Persons

RECOMMENDATION 10 - The Board does not recommend at this time that an administrative agency be created to adjudicate strict liability in hazardous waste cases.

There are two key factors to consider in deciding whether an agency rather than the courts should adjudicate liability. (1) Will there be enough claims to justify establishing a separate system? and (2) Are the cases likely to be so complicated that special judges or panels are needed to resolve them?

Concerning the first question, there is little actual proof yet that there will be a great increase in toxic tort cases, although it is logical to assume that there will be at least some increase due to the proliferation of chemicals in the last 20-25 years and the typically long time it takes to discover an effect. Furthermore, the implementation of a very stringent regulatory program should reduce the potential for injuries. At this point it seems premature to assume that the case load will justify a separate system.

Concerning the second question, the complexity of these cases will certainly be reduced if strict liability is applied, although the remaining issues of causation are highly technical and the use of administrative law judges with particular expertise might promote more consistent decisions.

The Board concluded that it is premature at this time to assume that the volume or complexity of hazardous waste liability cases will be so great that the general court system cannot handle them adequately.

RECOMMENDATION 11 - The Board does not recommend at this time that a fund be established for compensating injured claimants.

The advantage of a fund is that it would ensure that the money is available to compensate a person with a meritorious claim, that the compensation could be immediate and that identification of a specific responsible party would not be necessary. However, the fact that most of the facilities are required to have liability insurance for precisely this purpose certainly reduces the need for a fund. Furthermore, use of a fund entails some administrative costs that will increase the "transactional" costs.

If compensation is made from a fund rather than by the responsible party, then compensation is divorced from responsibility and has no deterrent value, unless the agency administering the fund is empowered to seek recovery from the reponsible person(s). Such a process has potential to increase even further the "transactional" costs. A fund would appear more appropriate in the abandoned or inactive site context, where the identity of a potentially responsible party may be unknown. This is the area Congress will be studying closely in connection with the report required by Section 301(e) of the federal Superfund law. California has adopted an "orphan site" fund to compensate those injured by abandoned sites, but that state is apparently the only one which has found such a system necessary.

Furthermore, any attempt to establish a fund would entail difficult problems of deciding who should provide the money for the fund, whereas direct compensation by the responsible defendant places financial responsibility where it should be. Mandatory liability insurance requirements should be adequate to ensure that the defendant will be able to provide compensation in most cases.

ATTACHMENT D

Superfunds and Tort Law Reforms—Are They Insurable?

By RICHARD A. SCHMALZ*

I

The "Superfund" bill enacted in 1980[1] is a federal law that imposes strict liability on certain classes of persons for cleanup costs and environmental harm resulting from the handling or disposal of hazardous wastes. It is the most recent in a series of federal statutes that promise to become the springboard for major tort law changes. Even without the superfunds, there has been considerable interest in tort law reform within academic circles, and the highest courts of many states seem eager to make their own marks in reshaping tort law according to their own views of public policy, but federal legislation can accomplish deeper changes more quickly than a dozen law review articles or judicial decisions, so superfunds and the tort law reform movement will feed on each other with a synergistic effect.

But are superfunds and tort law reforms insurable? The question is timely because a number of studies are under way, among them the study directed by the 1980 Act itself, a separate study by the Rand Corporation under the auspices of the Institute for Civil Justice, and other studies by various American Bar Association committees. Since studies rarely find the present state of affairs satisfactory, we can expect recommendations for affirmative action to correct the deficiencies as their authors see them.

Are superfunds and tort law reforms insurable? My answer is a cautious and qualified yes. The discussion which follows reflects the perspective of my thirty-five-year association with the property and casualty insurance business. Quite naturally, then, I raise points for consideration mainly from an insurance standpoint, but one should not overlook the broader social and economic aspects.

Tort law reform is inevitable. The only questions really open to debate are how it should be accomplished and how sweeping it should be. I believe a federal statute is the only feasible method of achieving the kind and scope of tort law reforms that are likely to remain insurable in private markets. I outline an entirely nonoriginal federal statutory system that I believe would enable private insurance and reinsurance markets to respond to the very high

limits of third-party liability insurance needed to support the concept of strict liability. Let us start with the Superfund bill in its 1980 version.

II

In some of the earlier proposals for superfund legislation, strict liability was also imposed for bodily injury and property damage to third persons. As finally enacted, however, Superfund does not include this feature, restricting itself to cleanup costs and environmental harm. Instead, Congress directed a study to be conducted with the assistance of the American Bar Association, the American Law Institute, the Association of American Trial Lawyers, and the National Association of State Attorneys General. The purpose of the study is to help Congress determine the adequacy of existing common law and statutory remedies in providing legal redress for harm to man and the environment caused by the release of hazardous substances. Accordingly, the study goes well beyond the scope of Superfund, as enacted, or its predecessor federal statutes dealing with clean air, clean water, and oil pollution.

The study group has been directed to submit its report to Congress with appropriate recommendations. The recommendations are to address explicitly the need for revisions in existing statutory or common law, and whether they should take the form of federal statutes or the development of a model code recommended for adoption by the states.

III

There is a certain equilibrium between tort liability-compensation principles and the underlying price structure of goods and products produced by a private enterprise economy. If that equilibrium is disturbed substantially, it may have an effect far beyond that which is desirable from a broader point of view.

Since the potential for disturbing the present equilibrium is great, it is necessary to start at the beginning and reexamine the premises on which a tort liability-compensation system may soundly be based under modern economic and social systems.

IV

Two basic general concepts apply to injury arising out of private or commercial activities:

(A) For every injury there must be compensation, regardless of the circumstances. The source of compensation is of secondary importance.

(B) A loss should be borne by the one who suffers it unless there is a good reason to shift it to another. Loss shifting requires justification. It is the exception, not the rule.[2]

Legal systems generally start from concept B. Concept A is by nature a broad social imperative which does not offer much as a means of resolving the competing claims of individuals.

Concept A implies compensation without fault. It serves as the model for a pure no-fault compensation system. Concept B implies some limitation on eligibility for compensation. There must be a good reason for the loss shifting. Let us call this good reason fault or wrong or tort. Concept B then becomes the model for a tort liability system.

Concept B carries with it a conscious choice not to use it or regard it as a means of compensating every injury. Therefore, it should not be a valid criticism of a tort liability system that some injuries or classes of injuries do not qualify for compensation. The chief exclusions are, almost by definition, those cases where there has been no fault in the legal sense and where, if there is such fault, there has been no causal connection between the fault and the injury in a mixed legal and physical sense.

These are the areas subject to the most pressure from critics of the tort liability-compensation system. A process that continuously relaxes the eligibility requirements for tort liability compensation leads to concept A.

As a general rule, the tort liability compensation system in the United States seeks to provide full damages for injury once the necessary fault and causal connection can be found. This requires putting a monetary value on all injuries, difficult though this may be. For bodily injuries, damages include compensation for medical expenses, lost earning capacity, and pain and suffering. The last element is hard to measure by objective standards and yet, in theory and practice, often overshadows the purely economic losses.

No large modern state has fully adopted concept A in a pure form. The administrative burdens and costs for a large state would be so enormous that such a concept is perhaps untenable for those reasons alone. Concept A has been adopted, in greatly modified form, as a part of legal systems. The main examples that come to mind with respect to the United States are workers' compensation and no-fault automobile insurance systems. Both are third-party liability systems that deal almost entirely with bodily injuries rather than property damage.

In each of these cases where the fault eligibility rule has been abandoned, it has been necessary to set the amount of compensation payable substantially below the level of full tort damages. Otherwise the total cost of the system would rise to unmanageable heights. An initial balancing principle emerges.

---

[2] Pfennigstorf, *Environment, Damages, and Compensation*, 1979 Am. Bar Found. Research J. 347, 363.

As we move from the concept of fault to no-fault, we must be prepared to accept lower compensation levels or risk unmanageable costs.

Neither workers' compensation nor automobile no-fault systems have eliminated the second important eligibility requirement of a liability system: the causal connection between the third party's activities and the bodily injury. For no-fault automobile insurance the third party's automobile must be involved in the accident and the accident must be the cause of the claimant's injury. In workers' compensation cases the injury must arise out of and in the course of a worker's employment. For most automobile and industrial accidents causal connection is rarely a problem. In workers' compensation occupational disease claims, however, the causal connection between work-related exposure and injury is often hard to establish with certainty.

There has been a trend toward easing the causal connection burden under workers' compensation laws in occupational disease cases. This has resulted in higher workers' compensation insurance costs. An extreme instance is the relaxation of burdens of proof with respect to black lung disease together with the imposition of retroactive liability. The cost explosion these have brought about has caused serious insurance problems and produced a system which may be running out of control from a financial standpoint.

This brings up a second balancing principle. *If we relax the causal connection requirement for a tort liability system, we risk unmanageable costs even if benefits are sharply reduced below full tort compensation levels.*

To achieve a purpose other than merely compensating every injury, the system must be rational and predictable on both the eligibility for and the amount of compensation. If it appears to be arbitrary or capricious, no message emerges by which individuals can be guided to act in accord with the system's purpose.

Interestingly, the condition of predictability is also essential for a system of private insurance operating under market pricing. When insurance is sold under competitive conditions to individual risks, the losses of each risk or group of risks must be predictable in order to determine an appropriate premium charge. When losses for any insured or group of insureds become unpredictable due to changes in the tort liability system, an insurance crisis usually follows. The recent crises in medical malpractice and products liability insurance are prime examples.

Critics are quick to express dissatisfaction with the tort liability system: it does not compensate every injury; at times it imposes difficult burdens of proof on those seeking to shift losses to others; and it has trouble dealing with the causal relation between certain exposures to hazardous substances and late-emerging injuries. A quick reaction is to set about curing these defects by imposing strict liability and by creating presumptions of a causal connection that cannot be rebutted any more convincingly than the connection could be proved directly. But such a course undercuts the rationale of the tort liability system and its predictability and risks unmanageable costs and insurance crises.

V

The ideal foundation for a workable third-party liability system would be a sound, generally accepted definition of: (1) its purpose; (2) the reasons why it is better to shift losses to some third parties than to leave them on the injured person (or the injured person's insurer); (3) who these third parties are; and (4) the circumstances under which the loss shifting is to take place. Such a definition would enhance predictability and promote efficiency from an economic viewpoint. It is not surprising, then, that several American scholars in the legal and economic disciplines have been devoting considerable effort in recent years to developing a comprehensive theory of accident law based heavily on economic theory.[3]

This approach suggests that the major purpose of liability rules should be to reduce the costs of accidents, including the costs of avoiding accidents. The persons liable for accidents would be the cheapest cost avoiders (i.e., they would be in the best position to make a cost-benefit analysis between accident costs and accident-avoidance costs and to take appropriate action). Making such a determination involves applying economic efficiency and utility theories.[4]

Not all legal and economic scholars who have studied the matter believe that it is practical or sound, even theoretically, to base tort liability-compensation rules primarily on promoting an economically efficient allocation of society's resources. Cost-benefit calculations and interpersonal welfare comparisons are difficult, if not impossible, to make with much confidence in most cases.

England, a lawyer, notes that "[c]areful behavior may be cheap in itself, but the effective avoidance of all the small human errors would probably exceed the totality of society's resources. A truthful cost-benefit calculus of total accident avoidance would therefore in most cases leave the loss where it falls."[5]

---

[3] Perhaps the prime mover in this effort is Guido Calabresi, who has written extensively on this subject. His major work, The Costs of Accidents: A Legal and Economic Analysis (1970), is well known. Richard Posner has developed an economic theory of negligence and contributed many scholarly papers. The Journal of Legal Studies, published by the University of Chicago Law School, is replete with articles devoted to an economic analysis of the law. The three-part series of volume 9 (Jan., Mar., and June 1980) is especially useful in gaining a perspective on the state of American legal and economic scholarship in this area.

[4] For a discussion of some conceptual problems and inconsistencies, see Dworkin, *Is Wealth a Value?*, 9 J. Legal Stud. 191 (1980).

> Utilitarianism supposes that individual welfare levels are at least sometimes comparable, so that total or average utility levels can be ordered over various choices of social programs. Economists, as a group, have been skeptical about interpersonal comparisons of utility. If utilitarianism is to be the motor of wealth maximization, then wealth maximizers must forgo that skepticism and move even further from present orthodoxy in economics.

Id. at 216.

Rizzo, an economist, concludes that

> [e]fficiency, as normally understood, is impossible as a goal for tort law. The law cannot and should not aim toward the impossible. . . . Precisely because we live outside of general competitive equilibrium and in a world of unpredictable flux, the efficiency case for negligence must fail. In such a world it is impossible to compare alternative liability systems, in terms of judicial cost-benefit analysis or "fine tuning."[6]

Some forty years ago, Prosser clearly perceived the social engineering aspect of tort law, writing in his classic *Hornbook on Torts:* "Perhaps more than any other branch of the law, the law of torts is a battleground of social theory."[7]

Twenty-five years ago Harper and James observed that

> [i]n the long run, the law tends to respond to its function and there are strong pressures at work toward making accident law serve at least some of the objectives of social insurance. It is in a transitional stage, where professed doctrine and purely logical reasoning from it will not accurately reflect the course of decisions or furnish a safe guide to what courts will do in the future. However little one may be concerned with law reform he cannot understand what is actually happening to the rules in this branch of law today unless he appreciates the trend towards social insurance and the relationship between this trend and the evergrowing institution of liability insurance.[8]

The process of transition has not slowed down. Englard has more recently (1980) noted:

> In general, the cause of the present crisis can be ascribed to a shifting in the aims and functions of tort law. Traditional tort law has been concerned with redressing a certain wrong committed by the tort feasor towards his victim. It is "corrective justice" between two parties based on the concept of fault with a clear moral connotation: the blameworthy injurer must compensate the innocent victim.

> The growing number of accidents created social pressure for the compensation of the victims, which was facilitated by liability insurance. The consequent penetration of distributive goals undermined the deterrent and retributive function of tort law. The traditional concept of fault itself underwent changes. The persistent tendency towards distributive aims weakened the idea of moral culpability by objectifying the elements of fault and causation.
>
> ....
>
> The acute crisis of conflicting aims has been aggravated by the fact that the dominant elements of loss spreading have developed outside the framework of traditional tort law. In particular, the systems of social and private insurance have been created quite independently from specific rules of liability.
>
> ....
>
> The traditional corrective-justice pattern of tort law has proved to be universally inadequate to overcome this conflict of aims and functions. One has only to consider the frequent case where both tort feasor and victim are covered by insurance. The whole tort process in which the court painstakingly labors to elucidate the minute facts of the damaging occurrence appears futile in view of the final allocation of the loss. The actual result of the trial may simply be a mode of accounting between two big insurance agencies. It is little wonder that modern tort law has been described as "schizophrenic, at cross-purposes."[9]

These observations show that, unfortunately, there is not much chance of identifying any single unambiguous, universally accepted purpose underlying the tort liability system. The emphasis will continue to shift toward concept A with less and less importance attached to individual responsibility or fault. Several legal theories now allow a plaintiff to avoid the burden of proving that an individual firm caused harm if the plaintiff can show that the firm is one of many firms marketing essentially the same product. Strict liability is favored over negligence by several scholars.[10] Some would argue against allowing even contributory negligence as a defense on the claim that it promotes economic efficiency,[11] although others do not agree.[12]

---

[9] Englard, *supra* note 5, at 27-29.

[10] *E.g.*, Epstein, *A Theory of Strict Liability*, 2 J. Legal Stud. 151 (1973). But note a partial retreat for products liability, R. Epstein, Modern Products Liability Law 28 (1980):

> The arguments just made on behalf of strict liability, even if conclusive in cases involving strangers, to which they apply, are therefore of but limited relevance in products liability situations. They say in effect that strict liability and not negligence should govern whenever an innocent bystander is injured by a defective product made and marketed by the defendant. These same arguments are, however, of no particular relevance to the vast bulk of products liability actions brought by purchasers, users, and consumers of particular products.

Striking a fair and reasonable balance between emphasizing compensation and retaining the concept of individual fault in the traditional sense requires thoughtful consideration of important public policy questions. As we move from concept B (the fault-based corrective-justice system) toward concept A (the pure no-fault compensation system), the scarce resources available to society will be reallocated in different dimensions and directions. American goods and services will cost consumers more, and American industry may become less able to meet foreign competition unless compensation levels are lowered from present tort standards and the distribution costs of the tort system are improved.

One implication of this shift is that lawyers will become less and less involved in pressing accident claims. The system will become more automatic, more like social security. Another is that general damages will have to be reduced or eliminated. All this will bring forth strong opposition from the bar. No doubt claims will be made by some advocates of change that in addition to providing more adequate and more just compensation, society will benefit greatly by a stronger impetus toward accident prevention and "internalization" of costs. These claims are window dressing. The truth is that the more the concept of individual fault is eroded, the less effective the transfer of loss is as a spur to accident-proof conduct; the weaker the causal connection between a tort feasor's activities and an injury that has many possible causes, the greater is the chance that somebody else's costs are being "externalized."

The policy questions involved in an accelerated shift toward more liberal tort liability rules need a solid economic analysis, although perhaps not along the same lines taken by the economic school of tort liability reformers mentioned earlier. I believe that many of these reformers have overemphasized the ability of the tort system to deter unsafe conduct as it evolves to strict liability and more relaxed compensation rules. In any event, it appears that they have not carried the analysis far enough in relation to the ability of society to afford full tort compensation under such conditions.

---

11. *See* Rizzo, *supra* note 6, at 317. Rizzo, however, backs into this position. He demonstrates that it is impossible to make the cost benefit analyses needed to determine efficient liability assignment under negligence and foreseeability tests. He prefers strict liability because it is simpler and results in "greater certainty about the locus of responsibility for accidents. This greater certainty promotes efficiency in the basic institutional sense because property rights, in effect, become more clearly or definitely defined." Rizzo, as he of course intended, has abandoned the classic definition of economic efficiency and substituted a new concept of institutional efficiency.

12. Rubin, in *Predictability and the Economic Approach to Law: A Comment on Rizzo*, 9 J. Legal Stud. 319, disputes Rizzo's claim for increased efficiency, even as Rizzo has redefined it, concluding at 334: "Adding a non-economic standard of liability, as proposed by Epstein and defended by Rizzo, would also substantially add to decision-making costs." See also Shavell, *Strict Liability versus Negligence*, 9 J. Legal Stud. 7, n.11 (1980): "It is of course clear that under strict liability without the defense the outcome is inefficient, for victims would have no motive to take care."

Any compensation system is only as good as the financial resources behind it. Heavy reliance will be placed on some form of private or government insurance. If the present mood in Washington continues, there will be more interest in private solutions to the problem of making sure that adequate security is in place. If costs of the tort system escalate, the private solutions may look more like government-sponsored quasi-private funds drawing their resources from special assessments or fees.

Accordingly neither the insurance industry nor industry as a whole can overlook the importance of the economic analysis suggested above. One must ask what kind of a system is rational for America, and in a changing world what kind of system will maximize the development of efficient private insurance markets to support it.

VI

The private insurance market in the United States has developed two kinds of insurance to accommodate the traditional fault-based, corrective-justice tort system. This is the system that applies to almost all commercial activities. For those cases where the loss is shifted from the victim to a tort feasor, third-party liability insurance is available through insurance policies issued to each firm. The policies indemnify against legal liability. Loss is shifted initially from the firm to the insurance company. The insurer in turn shifts it to its other policyholders, reinsurers, and stockholders. Unless the firm is a very small one, however, the firm's own loss experience will have a marked, direct effect on the firm's insurance premiums under the usual experience rating, retrospective rating, and dividend plans applicable to commercial liability insurance. The larger the firm is, the more likely it is that over time its own losses will determine its own premiums.

The wide popularity of experience rating, retrospective rating, dividend, and cash-flow plans demonstrates that firms are almost universally interested in insurance that reflects their own experience as individual productive units whenever that experience measures their true loss potential reasonably well. The cost of at-fault accidents is, then, largely internalized, often even to individual firms, but if not that specifically, at least to rating classes made up of firms conducting similar activities. In the main, group liability insurance policies have not become widely popular.

For those cases where traditional tort principles do not shift the loss from the victim, first-party coverage is widely available through individual policies issued to victims or to their employers.[13] Losses covered include physical

---

[13] 13. The Interagency Task Force on the Health Effects of Ionizing Radiation, in the Report of the Work Group on Care and Benefits (June 1979), notes at 34 that:

> Many persons have coverage under a private health insurance plan which pays benefits regardless of an injury's cause. In 1975, an estimated 168 million persons or nearly 80 percent of the population had coverage for hospital care, and a majority had some protection

damage to homes and business property, vehicles, death, disability, hospitalization, medical expenses, and so forth. In this area, group policies are more common and there is less tendency to differentiate finely among the loss potential of individual victims.

A possible partial explanation of the wider use of group policies is that fault is not a consideration in the determination of benefit eligibility. Losses are, therefore, shifted from the individual to larger, less refined rating classes. The compensation available through first-party coverage is generally restricted to economic loss, except for life and accident insurance, and often has sublimits on benefits for medical expenses or work loss to discourage overutilization.

I do not intend to suggest that the combined third-party and first-party systems do not have any gaps that leave some victims without compensation for some injuries or losses. I wish mainly to outline the general scope and nature of the two forms of private insurance that have evolved to accommodate the traditional concept B approach to tort law loss shifting.

The outline points out, however, that the present practice of issuing third-party liability insurance to individual firms under various experience rating plans supports the corrective-justice and accident-deterrence rationales of a tort liability system. And the nature of first-party insurance, with its generally more-limited approach to compensation levels, suggests that if one tries to fill all gaps in the total compensation scheme by expanding eligibility under the tort system, then the possibility of an unmanageable cost explosion becomes real indeed. The tort system has much higher frictional costs and compensation levels than first-party insurance systems.

The private insurance system has been able to accommodate strict liability as a substitute for negligence, and the weakening of certain defenses such as contributory negligence, when there is a clear causal connection been a firm's activities and an accident. For example, aircraft accidents can be dealt with on a strict liability basis without eroding the corrective-justice or accident-deterrence goals of a tort liability system. In this case, the predictability of aircraft accidents and the proper allocation of losses to a single firm is not undercut by a strict liability rule.

The insurance system begins to have serious problems when strict liability is imposed on numerous firms at the same time for the same injury, especially when the injury cannot be causally linked to any particular policyholder, time period, or industrial activity. The chaotic situation with respect to liability and insurance coverage for asbestos-related injuries is a prime example of how marked shifts away from the requirement of clearly

---

against the cost of physician's services, surgical care, and prescribed drugs. Most of the growth of private health insurance has been in employee group plans. However, approximately 18 million people do not have any health insurance or access to free care, and more than one-half of all Americans do not have adequate health insurance coverage for the catastrophic expenses which may result from cancer.

identified individual fault and causation as the basis for liability can create havoc for an insurance and industrial system geared to those principles.

The case for moving the tort liability rules for hazardous wastes even closer to liability without fault or specific causation rests largely on characteristics of the disposal of chemical wastes, which are thought to be analogous to the handling of asbestos. There are many firms that have been engaged for many years in producing industrial wastes. Injuries often become manifest long after exposure. And, as far as we know, the injuries may just as well result from natural or other unidentified causes. At best there is a statistical indication of an increased frequency of injury over the rates observed under other conditions.

It can be expected, then, that a general easing of the loss-shifting burden with respect to hazardous wastes will have the same effects on industry and insurance as those we are seeing in asbestos and black lung cases unless great care is taken to control costs and minimize impediments to a sound private insurance system. I believe there are some steps that can be taken to do this, without passing judgment on the wisdom of expanding tort liability remedies for hazardous waste disposal activities.

VII

If a tort liability system is to impose strict liability and still retain any appreciable element of its historical corrective-justice or accident-deterrence function, it should place strict liability on one and only one firm at a time. And where one firm is to be held strictly liable that firm should be the only firm liable to the injured persons.

Spreading strict liability over every firm forever cannot possibly encourage economic efficiency.[14] Nor can an insurance market respond with peak efficiency to such a condition, or to a condition where one firm is strictly liable at one time but all other firms remain liable on some other ground forever.[15]

Fortunately, we do not have to create a new tort liability-insurance system out of whole cloth. There are some well-conceived models designed to maximize insurance capacity under the rules of strict or absolute liability. These models arose in the late 1950s and the early 1960s to deal with the production and use of atomic energy on a wide scale for peaceful purposes.

In the United States we are more familiar with the Price-Anderson Act of

---

[14] There is a problem of plurality here. Not every firm at all times can be "the cheapest cost avoider." Note also Shavell, *supra* note 12, at 465: "Under strict liability it is not hard to imagine circumstances where a party decides against engaging in an activity when it would have been socially worthwhile for him to have gone ahead."

[15] This seems obvious to those in the insurance business, but the point has also been recognized by outsiders. Note Pfennigstorf, *supra* note 2, at 419: "The growing tendency to impose strict liability for large-scale industrial pollution has greatly increased the demand for liability insurance protection but has also multiplied the problems of evaluating the risk exposure, defining reasonable limits for the coverages, and calculating adequate prices."

1957.[16] The Paris Convention of 1960 and the Vienna Convention of 1963 covered similar ground. All have common features that would be useful in treating the liability and insurance problems associated with hazardous wastes. All are designed for risks of an exceptional character for which common law rules and practices are not suitable.

First of all, *they are not general purpose systems*. They focus only on the *exceptional risks* associated with a certain type of industrial activity. In their case, the activity is the production and use of nuclear material, including the supply of parts, materials, and equipment; the transportation of nuclear materials; and the treatment, processing, or disposal of nuclear wastes.

Whenever risks, even those associated with nuclear activities, could properly be dealt with through existing legal processes, they were left outside the system. This feature, which was adopted both in the United States and in Europe, requires the identification and separation of the low-hazard activities from the high-hazard risks. The separation has actually been made on several bases, such as the type of production or utilization facility involved, the nature of the particular activity, the quantity and type of nuclear material at hand, and the seriousness of the consequences of an accident.

While there was considerable philosophical debate in some quarters about the appropriateness of a "threshold" concept, the best judgment of the many experts here and abroad who considered the insurance and liability problems was that a reasonable threshold is required as a balance to the imposition of strict or absolute liability and the expanded eligibility for compensation that arises once the threshold is crossed. The threshold concept also allows insurance companies to develop the most efficient means of providing high limits of coverage for the exceptional, high-hazard risks while retaining their normal practices for the less hazardous risks. High-hazard risks are particularly suited to pools, but pools are not the best or most efficient means of insuring low-hazard activities.

The second feature of the atomic energy models is that, directly or indirectly, strict or absolute liability is the rule. The drafting comments on the Paris Convention emphasize that "[t]his does not, however, mean that merely to engage in a nuclear activity or to transport nuclear substances is to be considered in itself as a presumption of fault; but where an incident occurs, the liability of the operator of the nuclear installation concerned is absolute."[17]

The implication of this comment is that the drafters of the convention are not adopting a concept of enterprise liability. There must be an actual causal connection between the installation concerned and the incident giving rise to the injury. This conclusion is strengthened by the third feature. Directly or indirectly, all liability is channeled to one person—usually the operator of the nuclear installation where the nuclear incident occurs.

---

[16] Pub. L. No. 85-256, 71 Stat. 576.

[17] The English text of the Paris Convention of July 29, 1960, with the drafting comments, is included in Joint Committee on Atomic Energy, Selected Materials on Atomic Energy Indemnity Legislation, 89th Cong., 1st Sess. 256-90 (June 1965). The quotation is at 274.

The conventions accomplish this by provisions that explicitly state that only the operator is liable for nuclear incidents at installations. Price-Anderson reaches the same result indirectly by requiring operators to maintain liability insurance or other equivalent financial protection covering not only the liability of the operator but also that of any other person.

The Price-Anderson approach is a practical method of channeling exclusive liability onto the operator of nuclear installations because the total number of installations is still rather small (about seventy) and is likely to remain so. Furthermore, the insurance is furnished through two pools which cross-reinsure each other. Together these pools have attracted nearly all of the free world insurance and reinsurance capacity. Possible cumulation of exposure is eliminated under liability policies issued to suppliers and transporters by standard exclusions of the nuclear hazard. However, their liability is covered under the policies issued to the nuclear installations. Strict liability is imposed for "extraordinary nuclear occurrences" (a threshold based mainly on off-site radiation levels, number of persons with immediate signs of injury, and dollar amounts of property damage). This liability does not stem from statutory changes in underlying state tort law, but from compulsory waivers of traditional common law defenses in the financial protection requirements of the Price-Anderson Act, the Nuclear Regulatory Committee's regulations, and the underlying insurance policies.

We probably could not construct today a similar, essentially nonstatutory channeling of exclusive and absolute liability for nonnuclear waste handling and disposal activities. The nuclear conventions, which require statutory implementation at a federal level, will therefore serve as more appropriate models. The Paris Convention is worth study because of its helpful drafting comments and its careful treatment of the key concept that, with rare exceptions, only one operator is liable for the injury resulting from a nuclear incident.

The nuclear fuel cycle can be divided into three segments: (1) the refining, fabrication, and production of nuclear fuel; (2) the utilization of the fuel or radioactive by-product materials; and (3) the handling, storage, and processing of waste. The transportation hazard can arise at several points in the chain, creating another distinct group of firms called transporters.

A similar cycle can be constructed for other toxic or harmful substances which result in hazardous wastes. We might classify the production and utilization facilities as generators, the waste handlers as waste disposal sites, and the remaining firms as transporters. This similarity of higher-risk sources can be kept in mind while reviewing the liability rules for nuclear activities.

Under the Paris Convention the operator of a nuclear installation is liable on proof that damage or loss was caused by a nuclear incident involving nuclear fuel, radioactive products, or waste in, or nuclear substances coming from, the installation. There are some exceptions for transportation accidents and some priorities when more than one nuclear installation is involved.

In accidents involving the transportation of nuclear substances, the direction of transportation becomes important. The operator of the nuclear installation *from which* nuclear materials are being shipped is the focal point. This operator is liable for a nuclear incident outside the installation if (but only if) the incident occurs: (1) before liability with regard to nuclear incidents involving the nuclear substances has been expressly assumed by written contract by the operator of another nuclear installation; or (2) in the absence of such an express assumption, before the operator of another nuclear facility has taken charge of the nuclear substances.

The operator of a nuclear installation *to which* nuclear substances are being transported is similarly liable for a nuclear incident outside that installation only if the incident occurs: (1) after he has expressly assumed liability by contract; or (2) in the absence of such an assumption, after he has taken charge of the nuclear substances.

The operator liable under the Paris Convention must provide the carrier with a certificate issued by or on behalf of the insurer or other financial guarantor furnishing the security required by the convention.[18]

The priorities under the Paris Convention are as follows:

(1) If the nuclear fuel or radioactive products or waste involved in a nuclear incident have been in more than one nuclear installation and are in a nuclear installation at the time damage is caused, no operator of any nuclear installation in which they have previously been shall be liable for the damage.

(2) An exception is made to rule (1) for damage caused by a nuclear incident occurring in a nuclear installation and involving only nuclear substances stored therein incidentally to their carriage. In such cases, the operator of the nuclear installation shall not be liable where another operator or person is already liable.

(3) If the nuclear fuel, radioactive products, or waste involved in a nuclear incident have been in more than one nuclear installation and are not in a nuclear installation at the time damage is caused, no operator other than the operator of the last nuclear installation in which they were before the damage was caused or an operator who has subsequently taken them in charge shall be liable for the damage.

A catchall clause provides for joint and several liability in the rare case where more than one operator becomes liable under the Paris Convention. If it is a transportation accident involving the same means of transport, or, in the case of storage incidental to transportation, in the same nuclear installation, the maximum total amount for which the operators are liable is limited to the ceiling on liability established by the convention, and no one operator is required to pay more than the operator's individual ceiling.

---

[18] There are optional provisions under which the carrier, at the carrier's request, can be held liable for transportation accidents in place of an operator who would otherwise be liable.

The liability provisions of the convention expressly state that the right to compensation for damage caused by a nuclear incident may be exercised only against an operator liable for the damage in accordance with the convention or, if a direct right of action against the insurer or other financial guarantor is given by national law, against the insurer or other financial guarantor.

No other person shall be liable for damage caused by a nuclear incident, except that the convention does not affect the liability of any individual for certain damage to nuclear installations or means of transport resulting from an act or omission of that individual done with intent to cause damage.

This summary of the Paris Convention shows the care taken by the drafters to focus liability on one operator, usually the one in charge of the nuclear material by possession or the last possession.

The drafting comments explain that two factors have motivated the channeling of all liability onto the operator in derogation of the rights of an injured person to sue the person causing the damage under the law of torts. First was the desirability of avoiding difficult and lengthy questions of complicated legal cross-actions to establish in individual cases who is legally liable. Second was the need to avoid special insurance which would otherwise be necessary to cover the liability of all those who might be associated with the operation of a nuclear installation as well as the liability of the operator, which would be very expensive and might not be available.

The principles underlying the convention's approach to establishing liability rules seem far sounder from an insurance point of view than many of the superfund-like proposals. These in the main have no threshold, impose absolute liability without limit on a plethora of potential defendants, and are not exclusive of other remedies. Proposals of this nature magnify the insurance problems which are already becoming nearly unmanageable under the present expanding tort liability rules in the United States.

For the purist, the Paris Convention rules will not serve fully the traditional principles of individual corrective justice embodied in the tort law. But because they do require a clear identification of a particular installation, the imposition of strict liability is not nearly as ambiguous as it is under enterprise liability. It is also more likely that costs will be internalized.

How might the Paris Convention rules be used to construct a new tort liability-insurance system in the United States for nonnuclear hazardous substances?

VIII

The new system would require a federal statute, perhaps modeled on the Price-Anderson Act, but with additional features. The major functions of the statute would be:

(1) To identify the area of application, for example, the generators,

disposal sites, and transporters of hazardous wastes

(2) To set the threshold above which strict liability will apply
(3) To set out the rules imposing strict liability on only one firm
(4) To set out the limits and means of providing financial protection
(5) To set an overall ceiling on liability at a reasonable level
(6) To set reasonable limitations on damages recoverable
(7) To establish exclusive liability under the federal statute; that is, to preempt state tort law

It may be necessary to require a higher level of financial protection than the amount of insurance now customary. This would be the quid pro quo for the limitation on liability for all injuries which are the result of a single incident. While the ceiling should not be unreasonably high (perhaps in the range from $500 million to $1 billion), it will probably exceed the amount of private insurance available for some time. It may therefore be necessary to split the total financial protection into two segments. Primary financial protection could be set at the maximum available from private insurance companies. Secondary financial protection could be made up by a participating plan financed by equitable contributions from all generators, waste disposal sites, and, if desirable, transporters.

The primary financial protection serves two purposes. It guarantees that a fairly high level of funds will be immediately at hand to discharge the liability of the firm that is strictly and exclusively responsible. This ensures a prompt response. The finger is pointed at one firm and one insurer. It also internalizes a fairly high level of cost on the firm that is identified as being strictly liable under the statute. The liability rules based on the Paris Convention would do a good job of putting liability on the firm that has perhaps the best opportunity to avoid the accident. This brings both the liability rules and the insurance system into harmony with the more traditional tort law objectives and the newer economic efficiency arguments.

The secondary financial protection operates as a "stop loss" for the firm exclusively liable. At the secondary level the financial burden of exclusive strict liability is spread to the industry as a whole. One might look at it as a form of enterprise liability but at an excess level.

The justification for enterprise liability at an excess level is that strict liability does not require or even make an inquiry into fault. To saddle one firm with both strict and extremely high liability at the same time is unjust. Other potential or actual contributors to the loss, immune from direct liability, should shoulder some of the burden. Excess enterprise liability is a method of providing contribution or subrogation rights which avoids a series of costly cross-actions or "actions over" based on traditional tort principles.

Secondary financial protection lends itself to a pooling arrangement. It can be totally postloss funded as under Price-Anderson, or partially prefunded and partially postloss funded. The legislation should allow private insurers to participate in the secondary financial protection and to have the same tax advantages as would be given to a government-created pool or fund.

Under a statutory structure as outlined above, using the Paris Convention rules, it should be possible for a vigorous private insurance market to develop for all firms subject to the federal system. The features which would strongly encourage a private system are:

(1) For all operations of all industrial firms except those involving materials or activities that fall under the regime, normal insurance markets can be maintained. These markets can respond at lower cost and greater capacity knowing that the higher-hazard activities will not be covered by their normal policies.

(2) For the higher-hazard activities the special coverage will be channeled to a relatively few clearly identified firms. These firms will be licensed and will be required to maintain adequate financial protection.

(3) Primary financial protection will be available from single insurers, but in addition there are likely to be one or more competing pools. These sources can specialize in the insurance of the higher-hazard activities. They can marshall the underwriting, loss-control engineering, and high-capacity reinsurance facilities needed. Reinsurers particularly will be able to participate to the maximum, knowing that they will not be subject to cumulation of liability through their reinsurance of other activities.

(4) The cost of processing claims and handling litigation would be greatly reduced as multidefendant litigation would be eliminated. Today the cost of defending industrial third-party liability claims is becoming almost as significant to insurers as indemnity payments. The astronomical cost of complex litigation is operating as a brake on insurance capacity in many areas.

There are some potential drawbacks in this type of system for insurance companies. The channeling of strict liability to a relatively few target firms carries with it an obligation to provide high limits to those firms. This may require pooling, a device which a number of companies do not view with favor. However, such a statutory scheme as outlined above probably will not provide greater need for pools or more encouragement to the formation of industry captives than will the rapid development of state tort law in the direction of enterprise liability. If the risks are large and the limits of insurance required are high, the sources of insurance also have to be large. This encourages pooling with or without a federal system.

IX

I believe that the trend of state tort law towards strict enterprise liability cannot be stopped. That being the case, it seems wiser to work for a uniform strict liability system that will result in a higher percentage of premiums (or loss dollars) going to the injured persons. The great expense of operating a traditional tort law system that has largely abandoned its traditional loss-shifting premises can hardly be justified.

Strict liability systems, however, can easily run out of control. They can make it impossible for private insurers to provide high-limit liability coverage at reasonable cost. They may also impose such heavy burdens on industrial firms that they will not be able to compete in world markets.

An approach which may have a broader appeal is to adopt strict liability with certain controls and features. These should strike a balance between (a) the eligibility rules for and the levels of compensation to injured persons and (b) reasonable limitations on industrial liability. If this liability is backed by solid financial protection from private sources, including insurance, those injured through industrial activities will be assured of greater total compensation than under the present hit-or-miss tort system.

The argument is often made that any limitation on the liability of private enterprises constitutes an unjustifiable subsidy as well as an infringement of the rights of claimants. This is a simplistic argument. There are three important practical limitations on the liability of private firms—the corporate form of organization, which limits liability to the corporation's assets; bankruptcy; and competition from world markets. Imposing unlimited liability for injuries is hardly worthwhile if there is not enough money to pay for the claims or if it destroys the source of private funds and jobs.[19]

The concept of a ceiling on liability does not imply that no further compensation for injured persons is justified. The concept recognizes that a ceiling is needed in return for expanded eligibility for compensation and that, above a certain point, there is no good reason under tort law to shift the loss to private third parties. Concept B forms the rational basis of tort law. It holds that loss shifting requires justification and is the exception, not the general rule. A formal statutory ceiling on liability (or the de facto ceiling imposed by the practical limitations on liability mentioned above) still leaves room for first-party insurance and governmental assistance.

The most important benefits of such a statutory system are that it will greatly improve the ratio of dollars paid to injured persons to the dollars paid for the system's operating costs and that it will enhance the ability of private industry, including the insurance industry, to marshall the funds needed to discharge the high level of absolute liability imposed.

---

[19] Shavell, *An Analysis of Causation and the Scope of Liability in the Law of Torts*, 9 J. Legal Stud. 463 (1980), states in more elegant fashion four sound reasons for limiting the extent of liability: (1) it may help spread risks; (2) it reduces the likelihood of the injurer being discouraged from engaging in a socially worthwhile activity by a crushing burden of liability; (3) if the probability of a high loss is underestimated, holding the injurer liable for the total loss does not increase the incentive to take care; (4) the potential for problems with multiple injurers makes it difficult to place liability too far out in the (unending) sequence of events flowing from the defendant's act.

Id. at 499-500.

ATTACHMENT E

H.R. ____

A BILL

To amend the Comprehensive Environmental Response, Compensation and Liability Act of 1980 to provide for apportionment of liability under the Act.

Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled, that this Act may be cited as the "Comprehensive Environmental Response, Compensation and Liability Apportionment Act of 1982."

SEC. 2. Section 107 of the Comprehensive Environmental Response, Compensation and Liability Act of 1980 is amended by adding the following at the end thereof:

> "(l) APPORTIONMENT - (1) The Response Trust Fund shall be a party in any action for recovery of costs or damages under this section.
>
> "(2) Upon motion and sufficient showing by any party, the court shall join to the action any person who may be liable for costs or damages under this section and any State which may have incurred costs or damages recoverable under this section or in which the costs or damages upon which liability under this section is based were incurred.

"(3) Any party found liable for any costs or damages under this section who establishes that only a portion of such costs or damages are attributable to his or her actions, shall be required to pay only for such portion.

"(4) If the trier of fact finds the evidence insufficient to establish each party's portion of costs or damages under paragraph (3), the court shall apportion such costs or damages, to the extent practicable, according to equitable principles, among liable defendants.

"(5) A defendant whose contribution to the costs or damages upon which liability under this section is based is not significant shall not be liable under this section.

"(6) The Response Trust Fund and the State or States in which the costs or damages upon which liability under this section is based were incurred shall pay any portion of the judgment in excess of the aggregate amount of costs or damages apportioned under paragraphs (3) and (4). The court shall apportion such payment in any manner these governmental entities jointly agree, or, to the extent these governmental entities do not agree, according to equitable principles.

"(m) POST-APPORTIONMENT ADJUSTMENT - After the court has apportioned costs or damages pursuant to subsection (l) of this section, each party who is to make payments pursuant to an apportionment under paragraphs (3) or (4) of subsection (l) may petition the court to reduce the judgment against him in order to alleviate or prevent serious hardship or gross economic inequity. The Response Trust Fund, any State or States in which the costs or damages upon which liability under this section is based were incurred, and the petitioner shall be the only parties to a proceeding under this subsection. The Response Trust Fund and the State or States shall pay any portion by which the court may reduce the petitioner's judgment. The court shall apportion such payment in any manner these governmental entities jointly agree, or, to the extent these governmental entities do not agree, according to equitable principles. In reaching its determinations under this subsection, the court shall consider the need to respond to other releases with Fund or State monies. Nothing in this Act shall be construed to permit a court to consider hardship, economic inequity or the need to respond to other releases with Fund or State monies in apportionment of liability under subsection (l).

SEC. 3. Section 302(d) of the Comprehensive Environmental Response, Compensation and Liability Act of 1980 is amended by striking "Nothing" and substituting "Except as provided in section 107(l) and 107(m), nothing".

Legislative History -

Since passage of the "Superfund" Act in December 1980, there has been much confusion about apportionment of the liability established in section 107 among liable defendants. This confusion results in part from the 96th Congress' failure to explain with sufficient clarity its intent in deleting "joint and several liability" language found in earlier bills. E.g., S. 1480, 96th Cong. 2d Sess. (1980); H.R. 7020, 96th Cong. 2d Sess. (1980). Comments of Congressmen and Senators during floor debate, the only legislative history addressing the compromise bill which passed, differ. 126 Cong. Rec. S14964 (daily ed. Nov. 24, 1980) (Sen. Randolph); 126 Cong. Rec. H11,787 (daily ed. Dec. 3, 1980) (Cong. Florio); 126 Cong. Rec. S15,004 (daily ed. Nov. 24, 1980) (Sen. Helms). EPA and the Justice Department have asserted a broad application of joint and several liability notwithstanding this deletion. On the other hand, academic commentators have contended that "it is . . . clear that joint and several liability was not intended." 1A Grad, Treatise on Environmental Law § 4A.04, at 4A-114. This confusion led to stagnation and litigation in the implementation of the "Superfund" Act rather than to the rapid cleanup of hazardous waste dumps that was intended by Congress.

This amendment establishes the general principles by which courts are to apportion the liability created in section 107. It provides the necessary guidance for courts to fashion the specific federal "common law principles to determine when parties should be severally liable" under the Act. 126 Cong. Rec. S14,964 (daily ed. Nov. 24, 1982) (Sen. Randolph). It is also intended "[t]o insure the development of a uniform rule of law and to discourage business[es] dealing in hazardous substances from locating primarily in States with more lenient laws." 126 Cong. Rec. H11,787 (daily ed. Dec. 3, 1980). (Cong. Florio). The apportionment rules herein enacted are similar but not identical to those applicable under the California "Carpenter-Presley-Tanner Hazardous Substance Account Act." CAL. HEALTH & SAFETY CODE §§ 25360-25366 (1981).

Paragraph (l)(1) states that the Hazardous Response Trust Fund, the "Superfund," is a party in any litigation under section 107. While private parties and federal or state authorities may settle a case without involvement of the Fund, when a dispute reaches litigation the Fund must participate to ensure that expenditures made are "consistent with the National Contingency Plan" and otherwise consistent with the purposes of the Act and to recover costs incurred beyond those for which it is liable under paragraph (l)(6).

Paragraph (l)(2) states that the court must join to any action under this section any party who may be liable for costs or damages recoverable and any State which may have incurred costs or damages recoverable under this section or in which the costs or damages upon which liability under this section is based were incurred. This paragraph is intended to insure that parties responsible for only part of costs recoverable are not singled out for special treatment when other potentially responsible parties are also known. However, where a potential defendant's contribution has not been significant, as described in paragraph (1)(5), he need not be joined.

Paragraph (1)(3) states the equitable principle that a party is liable only for his or her "fair share" of cleanup costs or damages under this section. For example, to the extent a defendant proves that he did not cause a portion of costs or damages, he is not liable for such portion.

Paragraph (1)(4) states the apportionment rule to be followed when the trier of fact finds the evidence insufficient to establish each party's portion of costs or damages. This paragraph applies, for example, where multiple parties have jointly contributed to the creation of an indivisible harm. A court may apportion liability on the basis of the relative lengths of time during which the defendants owned or had control over a site, the relative number and seriousness of releases caused by the defendants, the relative degrees of fault in causing releases, the relative volume of wastes attributable to each defendant, a combination of these methods or other such equitable principles. The governing principle in fashioning an equitable apportionment, however, should be each defendant's relative contribution to the problem, not the relative wealth of each defendant. A party may not be held jointly and severally liable for a necessary remedial action or cleanup costs except where there is no more equitable basis for apportionment.

Paragraph (l)(5) states the de minimis rule that a defendant whose contribution is not significant is not liable. For example, in a case in which more than 250 potentially responsible parties are identified but in which 30 of those parties are responsible for at least 80% of the total waste by volume at the site, it is important that litigation be limited to the more manageable group of responsible parties. Limiting liability to significant contributors, in accordance with commonly accepted principles of joint liability, is also consistent with the efficient use of scarce prosecutorial resources.

Paragraph (l)(6) states the rule of apportionment in situations in which some portion of liability cannot be attributed to any party. In such situations, the Response Trust Fund and the State are jointly liable for the non-attributable portion. The Response Trust Fund thus may bear the cleanup costs for partially "orphan" as well as totally "orphan" sites.

Subsection (m) provides a procedure through which a defendant found liable under section 107 may seek to have the court reduce the judgment against him in order to alleviate or prevent serious hardship or gross economic inequity. Liability is apportioned under subsection (l) on the basis of equitable principles which are not related to the defendant's ability to pay. Rather, the defendant's relative contribution to the problem is the basis for apportionment among liable parties. However, ability to pay is a factor which may properly be considered in deciding whether government or the defendant should pay costs or damages. For example, government must bear the costs assessed a party without any assets or prospect for obtaining such assets. Moreover, the bankruptcy of an ongoing business concern as a result of the payment of its admittedly "fair share" of a judgment under subsection (l) may not be in the national interest. Similarly, gross inequity can exist when a concern's present day customers are different persons than the concern's customers who "benefited" from its polluting activities in the past.

This subsection permits a court to consider ability to pay and economic inequity in reaching a determination as to whether the defendant or government should pay. The amount of money available in the Fund or from the State to respond to other sites and the need for immediate action at these other sites must be balanced against the hardship and inequity which payment may impose on the defendant. The final sentence clarifies that the defendant's ability to pay and the availability of monies from the State or the Fund are not factors to be considered in the apportionment required under subsection (l). Subsection (m) is not intended to permit a State or the Fund to reduce its payments under paragraph (1)(6), but any State or governmental subdivision thereof found liable under this section and whose liability has been apportioned under paragraph (3) or (4) of subsection (1) may petition the court for an apportionment adjustment under this subsection.

Section 3 indicates that, to the extent the apportionment principles stated herein are contrary to principles in other state or federal law, including common law, this section prevails insofar as liability under section 107 is concerned. However, this amendment applies only to the liability created under section 107 and does not affect liability under other federal or state law.

Mr. LEVITAS. Thank you very much, Mr. Light. We appreciate your analysis and submission on behalf of Mr. Freeman and yourself.

Mr. Baron, we welcome you and look forward to your testimony.

Mr. BARON. Thank you.

I am Fred Baron, an attorney in Dallas, TX, with a private law firm. We have an office here in Washington, also. I am licensed to practice law in the State of Texas and I have been associated in various other jurisdictions as trial counsel.

Since 1973 when I first became involved in a group of asbestos cases in Tyler, TX, representing approximately 400 victims, my law practice has been first, partially and now exclusively limited to representing individuals who have contracted diseases because of exposure to toxic substances. Our law firm now consists of approximately 30 employees, with all types of backgrounds, who handle only cases for victims of toxic chemical exposures.

I have served as chairman of the environmental law section of the American Trial Lawyers Association, in fact I was the chairman of that group when we voted to change our name to the environmental and toxic tort law section, indicating a change of emphasis on behalf of the lawyers.

As you know I served as the member of the 301(e) group and I recently published a textbook for attorneys entitled "Handling Occupational Disease Cases."

I would like to draw on those experiences in making my comments to this committee.

It appears that obviously the inquiry here is do we need statutory remedies for these types of problems? It would seem that there are three basic inquiries. First of all are there victims out there? If so, does the legal system provide adequate relief?

Third, if it does, is causation proof so difficult that it presents an insurmountable barrier?

First I would like to address the second question, is the legal system adequate? It has not always been that way but I believe that it is now moving in that direction. Common law shifts generally glacially. The development of the common law is something that has taken hundreds of years in this country and in England. Yet when I was researching my book on occupational disease I decided to try to find all of the cases reported describing compensation for victims of hazardous chemicals.

When I got to before 1973 and eliminated workers compensation cases I essentially found two cases, one involving a polluted river and the other involving a chemical plant that was spewing out hazardous chemicals in the neighborhood. Both were property damage cases and both provided compensation for victims but after a long series of appeals.

So what we are talking about in this area of law is a brand new area, something that has never really been litigated in and something which the common law has not completely developed at this point.

Moreover, I found that prior to 1973—I use 1973 because that was the date of the decision of the famous *Borel* v. *Fibreboard* case that permitted the use of strict liability for victims of asbestos exposure—prior to that time essentially there had not been challenges to these barriers put up by the common law and that in fact no one had really questioned whether or not victims should be able to be compensated.

These barriers are now falling. The statute of limitations has developed into a discovery rule in 43 of the 50 States that have limitation periods. The common law is moving rapidly to develop a type of law or at least rules of law that will now provide compensation for victims of toxic chemicals.

The problem with it is, however, that the cost of the system and the time concerned to make this evolution are not adequate at this time. I would say that if you punch in a statute of limitations, punch in toxic chemicals, punch in discovery rule limitations questions into your West Law machine, whereas 5 years ago you would have drawn a blank screen, the machine essentially goes tilt. There are now law reporters that do nothing but report cases involving toxic chemical exposure. There are now seminars being put on for lawyers all over the country, almost ad nauseum, discussing victim compensation remedies under the common law and there are numerous law review articles being written about these particular problems.

Again the problem with the system is the cost. A victim who is seriously injured doesn't have to worry about that cost because it is probably going to be economical for him to be represented by private counsel. Yet for a victim who has relatively small injuries although substantial to him, the cost of litigating through the third party system may be prohibitive. As this committee knows, plaintiffs' lawyers work on contingency fees which has a habit of making lawyers handle only those cases which are economically feasible. The $2,000 injury case although very significant to the victim, is not economically feasible to go through the common law system. Whereas with the $75,000 case or the $100,000 case, there are several lawyers who certainly are willing to get involved in those cases.

When people have those serious injuries and have a lawyer with a stake in the case, the lawyer is willing to invest in experts to determine the cause of the problem, and to determine the way it should be solved.

That is why the 301(e) committee developed a two-tier system. It was our belief that the common law was in fact adequate or will be adequate as it develops to handle those serious injury cases. Because of the cost of the system there has to be a way for victims to receive some quick compensation albeit limited that will see them through and limit their losses while they pursue a third party remedy if it is required.

Now, the question is, are there a large number of cases? It is obvious to me that there are. Our firm is now representing the downwinders in Dallas near the lead smelter that this committee investigated earlier representing somewhere in the range of 500 potential victims and somewhere in the range of a thousand property owners who have suffered damages as a result of the emissions from the RSR and Dixie smelters.

Our firm represents hundreds of victims of radiation poisoning and asbestos poisoning, we represent large numbers of farm workers who have been exposed to hazarous pesticides. Unquestionably the problem is there and unquestionably the victims are there. It is a question of being able to quantify the numbers. No one has attempted it at this point.

Now, I have serious questions with some answers given by Mr. Roisman, particularly with respect to: Are cases too complex and too difficult and can you win them? These were primarily issues concerned with causation. I take serious issue with him that it takes hundreds of thousands of dollars to work up a causation case. I don't believe that is true. I would say to this committee that airplane crash litigation is very complex for divorce lawyers but not for specialists in aviation law.

I would point out that that there is a new group of plaintiffs lawyers emerging, a toxic tort litigation group, who understand these issues and who are able to focus on the real issues in this litigation. Because of that focus they can now handle these cases efficiently and economically. Moreover, I would point to the Dallas lead case again where EPA spent hundreds of thousands of dollars and perhaps millions to identify whether or not a problem existed over many years. Our firm hired a group of nationally known soil scientists and researchers and after 6 weeks and $12,000 completed a study of the entire neighborhood pinpointing exactly where those lead problems existed.

We believe that the evidence we have now gathered is substantial enough to present the case to a jury. Yet again we could have gone on ad infinitum doing all types of studies that would probably be duplicative and not be necessary to the litigation.

Mr. Roisman was asked how many cases he had settled or had he won. He indicated he only handled one case. Our firm has handled hundreds of these cases and we have settled the great bulk of them. Perhaps 95 percent of these cases that go through the litigation process do settle with an award to the victim.

Moreover, of the cases we have tried, a very sizable proportion of them likewise result in plaintiffs verdicts.

Essentially I believe that the victim compensation scheme as we have outlined in our study, is the necessary way to protect those victims who need immediate limited relief. The study group specifically recommended that the common law remain intact and that it be permitted to develop over a period of years to fashion further and more substantial remedies to the victims of hazardous chemicals. This is essential not only as a stimulus to compensate the victims but as a stimulus to prevent these types of practices that have caused the problem to begin with.

If an industry is faced with open-ended liability they certainly are going to correct the manner in which they operate. Thank you.

[The statement of Mr. Baron follows:]

STATEMENT OF FREDERICK M. BARON

I am an attorney and member of the law firm of Frederick M. Baron & Associates, 8333 Douglas Avenue, Suite 1050, Dallas, Texas 75255.[1] I am licensed to practice law in the State of Texas and before numerous other courts including the United States Supreme Court. Our firm is presently representing claimants, as associated counsel, in several jurisdictions throughout the United States. Since 1973, my law practice has been almost exclusively limited to representing individuals who have contracted occupational diseases and who have retained our firm to pursue claims for monetary damages sustained by themselves and their families because of their impaired physicial condition.

In the course of my practice, our firm has represented hundreds of victims of asbestos disease, radiation exposure, lead toxicity and other similar exposures to hazardous substances. Our experiences have been both in the areas of worker's compensation and third party tort liability litigation. I served as a member of the Section 301(e) study group established under the 1980 Superfund Act. I have recently published a textbook for attorneys entitled *Handling Occupational Disease Cases* and would like to draw on my experiences to make the following observations for this Committee.

Although Ramazzini in the 17th Century wrote extensively of diseases "in the shops of craftsmen," still today many diseases caused by exposures to hazardous chemicals go unrecognized and consequently uncompensated. As stated by John F. Finklea, M.D., former Director of NIOSH:

"No matter how esoteric the causative agent, the diseases usually manifest themselves in relatively conventional forms. The problem is that their origin is frequently overlooked."

Occupational Diseases—A Guide to Their Recognition, p. iii (NIOSH Pub. No. 77-181, 1977).

Similarly overlooked, from a historical point of view, has been the manner in which victims of exposures to hazardous chemicals have been legally compensated for economic losses sustained. Before the Fifth Circuit's landmark decision in *Borel* v. *Fibreboard Paper Products,* 493 F.2d 1076 (5th Cir. 1973) applying the law of strict products liability to an asbestos related disease case, hazardous chemical/disease law amounted to a scattered group of cases and articles discussing the problems of victim recovery for occupational diseases under pertinent state worker's compensation laws. The failing here was not with the "available law" itself, but with the general lack of understanding by the medical and legal professions about chemically related latent injuries.

In the ten years following *Borel,* there has literally been an "explosion" in the number of claims filed and victims compensated. Using tools previously available, a whole new generation of "occupational disease lawyers" has created precedents for compensating victims of such hazardous materials as pesticides, benzene, lead, phosgene and radiation.

---

[1] Washington office: 1717 N Street, N.W., Washington, D.C . 20036, (202) 775-3784.

In the area of asbestos litigation alone, thousands of victims have been compensated. The claims have proven so successful that at least three major asbestos manufacturers have attempted to utilize the Bankruptcy Act (despite their admitted solvency) to press for Congressional relief from the payment of these claims.

The national attention that has been garnered by these alleged bankruptcies will have a deterrent effect on some of the questionable practices of other manufacturers of hazardous chemicals and should likewise create an even greater incentive for research on and the testing of the safety of new and old products. The incentive for manufacturers to "clean up their act" in response to this litigation has been a greater stimulus than the various environmental and safety regulations supposedly enforced by EPA and OSHA. The old articles of faith describing the pitfalls of hazardous chemical litigation are, by and large, no longer applicable in common law litigation.

This is not to say, however, that certain problems do not exist. The most glaring deficiency in our tort compensation scheme is in the handling of the case of the victim who has suffered a relatively minor loss. Although the common law damage suit may provide a substantial recovery for a seriously injured victim, it is often costly and time consuming. The tier one scheme suggested by the Section 301(e) study group established by the 1980 Superfund Act provides an excellent solution to this problem.

Under this proposed Federal administrative remedy, claimants could file for limited benefits for economic losses suffered as a result of exposure to hazardous wastes, as defined in the Act. The claim would be handled much like a state worker's compensation claim but the critical difference would be in the utilization of a series of rebuttable presumptions established by the Federal agency. Rather than requiring the injured individual to present expert testimony concerning the etiology of his condition, a rebuttable presumption (if applicable) would be created to establish a prima facia showing that the exposure caused the victim's disease. In the "routine" case, this would eliminate many of the costly procedures otherwise required to establish facts which really should be accepted as true. Because liability or fault is not an issue in these claims, they should be adjudicated in a reasonably expeditious manner.

Perhaps the greatest conflict among the members of the group was on whether or not to make this tier one remedy a truly exclusive compensation remedy for victims in exchange for eliminating the right to pursue common law remedies. Fortunately, the majority of our group recognized the inherent value in protecting the rights of injured claimants to receive substantial recoveries. Because of the deterrent effect of maintaining the unlimited liability of negligent producers and users of hazardous chemicals, the majority of the group voted not to eliminate common law rights.

The trade-off, if it can be called that, was an "exit toll" which essentially acts to penalize the over-litigious claimant and thus deter specious claims from clogging the court system. Although I would have preferred to eliminate this device entirely in favor of free access to the system, I am gratified that no serious consideration was given to eliminating the right of victims to receive common law compensation.

The common law remedy, utilized through our civil jury trial system, guarantees victims of hazardous chemicals their right to seek full and complete compensation for their injuries. Future abuses by those who economically benefit from the manufacture and use of hazardous chemicals will only be deterred when the generators of these materials, and not the public at large, are forced to bear the costs of injury. The asbestos experience has proved that the common law tort system, if allowed to function freely, will bring the injured victim to the doorsteps of guilty parties.

Mr. ROWLAND [presiding]. Thank you very much. I have two or three questions I would like to ask

Do you think the contingency fee system will contribute to the cost over all with reference to poison from the toxic chemicals?

Mr. BARON. Contribute to the cost of what?

Mr. ROWLAND. Over all?

Mr. BARON. I believe the contingency fee system probably reduces the cost of the entire process because I believe the contingency fee system weeds out those cases that are not practical to be brought and permits victims who have serious injury to go ahead and pursue those cases economically.

Mr. Rowland. Do you think it is better and less expensive to have that than it would be for an attorney to take a case and just be given a certain fee for handling this case?

Mr. Baron. I think the discussion we had earlier about the hired-gun theory, that some lawyers, when they are presented with an hourly rate, have a habit of pursuing cases that probably should not be pursued, and they will argue points that probably should not be argued.

The contingency fee system weeds out those types of cases from the system that is already clogged.

Mr. Rowland. I believe you stated that as a toxic tort litigation group, the attorneys are just now beginning to learn about the possibility of compensation for victims outside the workmen's compensation area for injury, and I believe you mentioned that lead poisoning was an example of that, and I believe you said it took many years for that to develop; that lead was indeed a toxic chemical.

Mr. Baron. Not so much that it took many years to develop the knowledge; the medical knowledge has always been there. You can go back in any medical textbook in the 1930's and read all you want to know about lead toxicity. The knowledge of how to develop these cases through the legal system is just now developing. That is where the problem is.

Our profession, the law profession, has been way behind the medical profession in identifying these problems and in dealing with them in terms of victim compensation.

The medicine has always been there.

Mr. Rowland. You don't think it took many years for the fact that lead is a toxic substance, to come about, although you mentioned that we did know this a good many years ago.

Mr. Baron. Mr. Rowland, in reviewing our lead smelter cases, we did a Medline and Toxline, computer-assisted research on the hazards of lead toxicity, and I think that by 1940 we had developed something like 85 articles that were in-depth studies of lead toxicity on children and adults and particularly downwinders from lead smelters.

There is a lot of information available prior to 1940.

Mr. Rowland. You don't think we need to have this evidence now for other chemicals?

Mr. Baron. I think we have to continue to develop the evidence; however, it has been my experience, unfortunately, in reviewing these cases, that the one type of evidence I don't really have a whole lot of difficulty in finding is knowledge of the hazard. That evidence always seems to be available in the literature. That is not the difficulty in the cases.

Mr. Rowland. Mr. Molinari?

Mr. Molinari. Thank you, Mr. Chairman.

I wonder if I could relieve you of a copy of that study report, Mr. Light? I have been trying to get my hands on that.

Could I ask one of the staff members to pick that up? Say yes, please.

Mr. Light. I can't refuse a Congressman.

Actually, Mr. Freeman's secretary, Jane Ketron, had me commit myself to bring this back, but since you have asked me in open hearing, I will release it and make her a copy of my own personal one.

Mr. MOLINARI. Thank you very much. I appreciate that. I look forward to some very intensive reading.

Let me start off by saying that the testimony we have heard from this panel is astounding. It is totally different from what I would have expected, not having read the report of the study group. It is somewhat contrary to that which we have heard over the past few weeks, and perhaps encouraging at the same time.

Mr. Baron, I want to just review with you, if I may, to make sure I understand in my own mind, your firm is a firm that has roughly 30 lawyers?

Mr. BARON. Not 30 lawyers; 30 professionals. We employ researchers and people of that nature. We now have eight lawyers. We have various staff members, too, that work with us.

Mr. MOLINARI. Your specialty is in this particular field?

Mr. BARON. That is all we do. We do handle toxic chemical exposures and disease caused therefrom. I think we are one of two law firms in the United States that do that.

Mr. MOLINARI. That was my next question.

If this is such a lucrative field, I wonder how many firms there are throughout the country that would be similarly situated, of the same size, and so on.

Mr. BARON. First of all, I would say that handling airplane crashes and scaffolding collapses, which is what I used to do years ago, is far more lucrative. We feel this work is far more important. Unfortunately, there are only a couple firms that do it on a full-time basis. There are now several lawyers who spend a great deal of their time if not the majority of their time, working on these types of cases.

Mr. MOLINARI. Couldn't we assume a certain relationship between the paucity of lawyers that are specializing in this field and the ability to recover under existing law?

Mr. BARON. I think that that probably is true. There are many of us who got into this field because of that reason, because we felt there had to be development in this area of law as it developed. As other plaintiffs' lawyers are now aware that recoveries can be made, the shift has been into this area by lawyers who have never dealt with it before. This is a good shift because these people are starting to understand the nature of these problems and, rather than litigate all around the problem, they are learning to focus directly on the issues involved and to fashion recoveries for their clients.

Mr. MOLINARI. Prior to 1973, research indicates there were only two matters that were litigated in this area, and both were property damage cases?

Mr. BARON. Cases where we could find appellate decisions, yes, other than workers' compensation cases.

Mr. MOLINARI. Yes, I understand.

Mr. BARON. I would point out that if you punch into Westlaw, the computerized legal research system, the issues we are talking about, the machine will go tilt with new cases that have been coming out. These issues are now seriously being litigated in appellate courts.

Mr. **Molinari**. Here is the problem that I have. I flew in this morning, and last night I had a town hearing on a local matter that is rather notorious in our area in New York city. It involves a municipal landfill. We had the Regional Administrator of EPA there, we had the Commissioner of Environmental Protection for the State of New York—both very knowledgeable people—and we had a hundred-some people from the area, all of whom were expressing concern for their families. They presented us with information that members of the family were suffering from certain problems, high incidence of asthma, rashes, loss of hair, bladder infections in the case of females, nosebleeds—the symptoms we have heard time and time again.

We are not even thinking about the liability factor. What we are concerned about is trying to determine whether there is a serious problem there, how serious it is, and what remedial steps can be taken.

This has been going on now for 19 months, and there have been two criminal trials in connection with toxic waste dumping at the landfill where there were convictions, one in a Federal court, and one in the State Supreme Court.

Despite the body of evidence indicating substantial amount of dumping, and the identification of about 10 chemicals and chemical compounds, all the medical experts have not been able to tell us how serious a problem we have.

If we look at the medical background here we find that the United States, EPA, the State, and New York City agencies all heavily involved, with New York State generally regarded as one of the forerunners when it comes to health matters. Now I hear that for attorneys with an expertise in the field, those who have particularly specialized, like your firm, it is not all that difficult to establish a legal case.

I have difficulty equating these two sets of facts in my mind.

Let me give you a hypothetical. Suppose we brought you to that area, and said, Mr. Baron, here is the problem. Is there a condition here?

Sure.

Can we provide you with the evidence that, in fact, large amounts of toxic chemical wastes were deposited there?

Sure.

Have there been people injured?

Well, you get an argument there, depending on whom you talk to. But if you talk to the people, as I have up and down the streets, there is no question about injury in my mind.

How do we take that next step? How do we prove that, in fact, the problems are there, health symptoms are there, and they were, in fact, caused by what is in that dump?

Mr. **Baron**. That situation is not analagous to the Dallas lead smelter case that I will have to use as my example. As you know, in 1972, the State and city determined that lead smelters had emitted too much lead, filed suit, and received an injunction. At the beginning of that point, EPA and the Federal agencies and the city and State studied the lead smelter and had not reached a conclusion as to whether or not there was a problem there.

We were contacted by the neighborhood residents, decided to go outside the governmental agencies, where politics were not involved at all, found people that we felt were qualified professionals that did not have an axe to grind one way or the other, and had them inspect the premise and inspect and examine the people.

We were able to establish a case very rapidly through these experts. That is not to say that EPA never does the job properly. Unfortunately, though, we found that in too many occasions, because of political pressures being placed on them at one point or another, their data cannot always be confirmed.

I believe that the outside expert, or someone who does not have any pressure placed on him when he does his investigation, might be the real source of proof for the lawsuit, if there is to be a lawsuit.

Mr. **Molinari.** Let's talk about that for a moment, if we may; the question of medical experts. We have heard repeatedly that it is extremely difficult, if not impossible, to be able to hire medical experts in this area; that there are few of them in the country; and we have heard figures of $350 an hour as being the cost for these high-priced doctors.

Mr. **Rowland.** I am doing the wrong thing.

Mr. **Levitas.** I think I am doing the wrong thing, too.

Mr. **Molinari.** Is there that serious a problem out there in terms of getting medical experts, not just for the lead situation, but in other areas as well?

Mr. **Baron.** It is something of the difference between Dr. Karrh and Dr. Carnow—you want to know who it is you are using—and, yes, if you take the number of physicians practicing in the United States and take the number of doctors qualified to work in this area, it is an infinitesimally small percentage. But there are health professionals out there who are available to do these types of studies and who are capable of rendering a decent, honest, sympathetic opinion.

Now, the issue then becomes how you find them, and that gets to the issue of experience of the attorney and knowing the sources of these individuals.

There are groups—in fact, Dr. Carnow has a large group in Chicago of professionals, health professionals—who are available for consultation on these types of issues. It is just a question of being able to identify them.

I might add, over the last few years their ranks have increased substantially. Again, 10 years ago, it was difficult to find them. Many young physicians are getting into this area, and many older physicians who are interested are now doing it on a more full-time basis.

It is just purely a question of knowing where to look.

Mr. **Molinari.** I think you did say that you disagreed very much with the figures given by Mr. Roisman for the cost of the medical and scientific workup.

Mr. **Baron.** I do, indeed.

Mr. **Molinari.** Let's leave the Dallas lead case aside; more typically we are dealing with somebody who lives near a dumpsite that is contaminated, who is experiencing symptoms such as I described before. What do you think it would cost for the necessary medical workup?

Mr. **Baron**. Again, the cost goes down per person if you have a large number of people. What you can do is bring in a team of health professionals and station them in a local physician's office and start seeing large numbers of them over a period of a week or two at a time.

If you have one person, an individual, I believe a complete medical workup could be completed for less than $1,000.

Mr. **Molinari**. How much?

Mr. **Baron**. Less than $1,000 for a complete medical workup of one individual. If you are talking about 250 people, you can reduce that substantially by the efficiencies of putting everybody in one place.

Mr. **Molinari**. What would that medical workup consist of?

Mr. **Baron**. It would consist of all types of—first of all, a thorough history to rule out any other possible causes for the problem; identification of what problems really are occurring; a routine physical examination, including perhaps x rays, if there is some nature of a suspect tumor or lung disease; blood tests; perhaps pulmonary-function studies; and whatever was necessary to describe the type of physical complaint that the patient was making.

Again, it depends on the type of problem. In the lead case you might want to do one thing, whereas in a trichloroethylene case, you may want to do a neurological exam.

Mr. **Molinari**. I am talking about specifically where you don't know the chemical.

Mr. **Baron**. Well, I think you have to identify generally what types of chemicals are there, and if you know where the source is, or if you have a reasonable belief as to the source, I think the first step would be to hire a qualified scientist to be able to quantify what the exposure essentially is.

Mr. **Molinari**. What would that cost in the case of one individual, roughly?

Mr. **Baron**. I would think roughly less than a couple thousand dollars to do a chemical analysis of the source. Probably substantially less than that, depending on the type of testing you wanted to do.

Mr. **Molinari**. Thank you, Mr. Chairman.

Mr. **Levitas**. Let me say this: We have a series of votes which have just begun on the floor, and it is going to keep us away for a period of time. I thought at the end of the second bells we would leave, and because we are going to be gone for a period of time, that we should at that point break for lunch for about an hour, and let you gentlemen recover your sustenance. I would then like to reconvene, because there are a number of questions I would like to ask all of you, and I can assure you your testimony in this hearing may very well shape the outcome of this legislation, and it is quite important.

So, if you—I notice, Mr. Lundquist, you are looking at your watch. Do you have a plane to catch?

Mr. **Lundquist**. I am not so worried about the plane; and with the hour break that will work out fine.

I have a plane this evening. I have a commitment at 1:30; perhaps I can handle that, or let the person know.

Mr. LEVITAS. If you could, because your testimony concerns the involvement we will have in writing whatever legislation is written, and I think it is very important in order that a proper record be made.

So, with that, why don't we recess.

Mr. MOLINARI. Yes, I think we should break now, Mr. Chairman.

Mr. LEVITAS. Those are the second bells that rang. Let's recess until approximately 2 o'clock.

The subcommittee will stand in recess until 2 o'clock.,

[Whereupon, at 1 p.m., the subcommittee recessed, to reconvene at 2 p.m. this same day.]

AFTERNOON SESSION

Mr. LEVITAS. The subcommittee will be in order.

The gentleman from New York.

Mr. MOLINARI. We discussed briefly this morning the question of the compensation type system administered on the State level—the tier 1 concept. The question I have is, where we have a State administering a program and the dollars that would be awarded would be Federal dollars, would we not run into the problem that since the State is not spending its own dollars, but that of a Federal, such and that there is little in the way of accountability factor the State would be more apt to be overly generous with awards?

Mr. BARON. One thing, they may be mischaracterized as Federal funds, because, as I understand the report we drafted, we would suggest that the funds come from some nature of a tax, very much like the Superfund money and it wouldn't be truly Federal funds.

Mr. MOLINARI. I understand that. I used the term "Federal", to distinguish that awards would be coming from other than a State-supported fund.

Mr. LUNDQUIST. One of the developments which one would hope for is that in dealing with an administrative system, you get a precedential value, so cases wouldn't go askew, so that in one jurisdiction you get $100,000 for one type of award and in another jurisdiction you get 25 percent of that. That is part of it.

Also, the damages that you get are pretty directly linked to special compensation needs. You are not getting pain and suffering damages—that sort of thing. You are really talking about strictly medical costs and a part of your loss of income.

I think that that is not as big a problem as it would be if you were making major awards for the general damage claim you usually get in a personal injury verdict.

Mr. MOLINARI. Is the recommendation limited to out-of-pocket expenses?

Mr. BARON. Yes.

Mr. LUNDQUIST. Yes, it is.

Mr. MOLINARI. No compensation for loss of salary?

Mr. LUNDQUIST. You get loss of salary, a partial compensation for loss of income, but again, that is a fixed amount.

Mr. MOLINARI. So you would have an open area with respect to the period of disability?

Mr. LUNDQUIST. You would have. There is a further limitation, that sees people making more than $36,000 a year wouldn't get full measure of loss. It is rather to give people basic levels. You get the percentage of your loss up to 36,000.

The disability period would be relatively openended.

I think the reason that that won't be a problem is that the case which has a lot of potential, which might get a large damage award, is going to be pursued by the plaintiffs. They will not stay in the tier 1 system for that.

Mr. MOLINARI. Has anyone in this group—Mr. Light?

Mr. LIGHT. Mr. Freeman, in his separate statement on Superfund report, refers to the problem you are talking about, sort of a two-part problem actually, a problem of figuring out what the States will need from year-to-year or from whatever period to whatever period, and that goes to the scope and dimensions of the problem, which you all have referred to earlier, and you really need to talk to actuarial types, insurance company people to get a feel for how that will work. And, second a claims management problem.

But I agree that as the system gears up and you have some experience on how it is operating, you may very well be able to do that more efficiently as time goes on.

Mr. Freeman personally felt that this could be a severe problem, based on the experience Congress has had with other types of administrative special funds, such as the Black Lung Fund.

The Superfund study group had a couple of ways that they tried to address this question, although I think Mr. Freeman would say they didn't address it sufficiently and Congress might want to look further.

One is that there would be a Federal agency which would prepare guidelines for the program. Although the States administer the program it would be pursuant to these Federal guidelines. There would also be a way to review the compensation award and that would generally be through the State court system, but there would be an appeal from the State court system to the Federal agency in charge of the guidelines when there was a difference of opinion between the claimant, say, and the State about the guideline. If there was an award that was not going to be made, you might appeal to the Federal agency.

Also, there would be a Federal judicial review when there was a problem of implementation of the guidelines. The Federal agency also could bring an action itself if it became aware of a problem in the State administration of the program.

The other control they built into the system was similar to what is in Superfund. The State would fund part of the administrative cost of the program. I believe they said it was 20 percent.

Mr. BARON. Ten or twenty, yes.

Mr. LIGHT. So there would be some State responsibility, built-in incentives that way.

Mr. BARON. One of our primary concerns and an area we discussed a great deal, was the conceptual and practical differences. Conceptually, you would like one agency to be able to do this. As a practical matter, looking at the black lung administration and at the Federal Employees Compensation Act administration, and in most Federal systems for giving out compensation benefits, we felt the State workers' compensation system was far preferable as a practical matter, in terms of efficiently doing the job.

Mr. MOLINARI. Dr. Rowland and I had an interesting little chat on the way to the vote. We had the typical conversation that might be held between a doctor and a lawyer.

Mr. ROWLAND. Very typical, yes.

Mr. MOLINARI. Sometimes in discussing whether the law should be enlarged to provide greater compensation, I have tried to, if possible, divorce my own ideas, which may be prejudiced by virtue of the fact that I am an attorney. Perhaps there is a greater sensitivity on the part of an attorney because he has been faced many times with the problem which sometimes has been described as insurmountable at these hearings. I would hope, certainly in my own case, that I am not looking to come up with a solution that would get lawyers fat.

By the same token, I think we all, doctors, lawyers, members of the panel, members of the subcommittee, would like to see some improvement on this system, so that those out there who have been harmed by exposure to toxic waste can seek some type of compensation without being put to the test which, until today, I had reason to believe to be an impossible one.

I just have one other line of questioning.

I find your testimony, Mr. Baron, to be very, very provocative from the standpoint of this Member of Congress. I have until today, regarded the problem of proof as one that is extremely difficult. In fact, referring to our earlier conversation today, we have about 700 lawyers on Staten Island, an area with some very serious environmental problems, but I doubt very much whether there would be a single lawyer out of those 700 who would take any of the cases. Any of the people of Staten Island who have had serious difficulties would have a problem getting a lawyer.

It is that type of case that can make a lawyer go broke. As you know, lawyers have that difficulty of starting out to evaluate a case. Is it going to pay for the time? Are we going to make up any office expenses on this?

I know there are many, many environmental lawyers out there. Yes, in my own area, there are any number in New York City that are highly regarded and well-trained in that field who would handle environmental causes.

But I don't find very many of them gravitating toward the field where they would be handling plaintiffs' causes of action such as your firm.

I wonder why? It would seem to be a natural.

Mr. BARON. That is a function of time. This is truly a new area of law and I emphasize that prior to 1973, really, prior to 1978, there were very few guidelines for lawyers who practice in this area, very few legal decisions that provided precedent.

That is changing now. We don't change that overnight. We don't see the system shift in 4 or 5 years to the extent of 180 degrees. But over that period of time, the natural changes in the law will identify lawyers who are more interested in getting involved in these types of cases.

I do know several lawyers in Manhattan who I believe would be very anxious to get involved in the type of case you have described.

It is just a question of being able to know who it is.

Mr. **Molinari.** Mr. Lundquist?

Mr. **Lundquist.** You have in your area some of the leaders, Mr. Paul Reingold and Norm Landau, I suggest as lawyers, however, there is another thing that Dr. Rowland might take comfort with; as lawyers we know of the phenomenon, when a bus gets in the accident, people don't rush off the bus, people rush on the bus.

Indeed, I have heard in connection with the MGM fire in Las Vegas where the expected normal count of 200 people at that time of day in the Casino came to be 14,000 when claims for smoke injury were received.

What this suggests to me is that when people read about something and get psychologically concerned and worry about it, it is because they also see the opportunity to get some compensation for pain and suffering.

Discerning lawyers for individuals weed out the cases. I tell the client you don't have a strong or just case. Indeed, we tried in this proposal to weed out cases so that, at the basic level, you can't get pain and suffering for the sort of things we see in court today where it is not uncommon in a toxic tort case to have somebody who has been exposed, or has an increased risk of injury, but no provable disability or disease, to put a psychiatrist on the case to testify that the fear of death, is worth compensation and indeed, in California, it is.

But this goes back to the point about the people who you meet and talk to who have asthma and other diseases, which may or may not be disabling. What we need to do is get those who are harmed compensated, and not face a lot of claims for those who don't.

It was an endeavor on our part with the two-tier structure to accomplish that.

Mr. **Molinari.** I think you touched on an area that is worthy of further exploration. That is, in many of these impacted areas, if that is the right term, another subject we were talking about today—the trauma effect—is a factor. How many or how much of the claimed injuries are psychologically induced?

I am one who always believed that the term "nerves" or "nervous condition" is one that is overworked. We have heard, interestingly enough, that one of the symptoms of toxic exposure is nerves.

Doctors have diagnosed health condition as nervousness or nerves. I wonder whether that condition is something that is triggered by exposure to these chemical compounds, or whether it is caused by the fear of the unknown or the fear of leukemia, for example, that might in victims' minds be associated with that exposure?

Is there any way of evaluating that? Do you have any experience with that?

Mr. **Baron.** We have. The only way you can do it is on a one-by-one, case-by-case basis. The real issue for this committee is whether the law should deal with that, and whether the law should provide a remedy for somebody who is psychologically affected.

I question whether that is something we should be attempting to do by passage of any law. Quite honestly, you are going to have to present proof on the issue of some nature which gets you back to the imperfect injury system where maybe the jury one day will believe the doctor who says that this person has a severe psychological problem caused by the chemicals; and maybe the next day, they won't believe him.

That is the imperfection of the system.

Mr. **MOLINARI**. I was somewhat referring not to those who truly have a nervous condition——

Mr. **BARON**. You are talking about psychological only?

Mr. **MOLINARI**. No, not psychologically induced but those whose physical problems manifest themselves in a condition that is diagnosed as nerves.

Mr. **LUNDQUIST**. All the time.

I have been in a courtroom and dealt with situations as follows: One, where someone has an increased risk of mortality, they put on experts to say how that affects his entire life, makes him want to commit suicide and as a result he should be compensated for the psychological injury.

I have also been in a situation where injuries were so severe as to be physically disabling. We have dealt with those situations in the court. To be cynical about it as a lawyer, there is also a respectable body of medical literature which establishes that a lot of this type of injury disappears after the cases are disposed by compensation or if they are lost.

You know, when you don't have that gnawing problem removed, it somehow goes away.

That is beyond my range of—notion of how——

Mr. **LEVITAS**. Will the gentleman yield?

Mr. **MOLINARI**. Sure.

Mr. **LEVITAS**. That is not an unusual medical-legal phenomenon.

Mr. **LUNDQUIST**. It is common, right.

Mr. **LEVITAS**. That is the old automobile whiplash case.

Mr. **ROWLAND**. The name given to that is greenback bogus.

Mr. **LUNDQUIST**. That happens when you have people reading a lot about them and the possibility of making a claim.

Mr. **BARON**. That gets to the di minimus problem, where if you have someone, we have represented clients with severe problems from trichloroethylene and other exposures and in those cases the disability was so severe that we have had toxicologists testify there is a cause and effect relationship and we have had large jury verdicts in them.

In other cases you have people able to function completely but it is just a concern and maybe is more nervous about it. Are we going to set up a system that costs $10,000 or $15,000 to deliver him a couple thousand dollars worth of benefits for that? That is the dilemma. That is the problem.

Mr. **MOLINARI**. It would seem to me that in adopting this recommendation, there would be some type of compensation schedule set up so that you would have to have some idea, beforehand, as to the costs that would be incurred.

I think Mr. Light touched on this before, and the question is are there actuarial studies? Is there any range of anticipated payouts that would occur?

I know it is difficult to estimate but before we could move in that direction I think we would have to have a handle on the projected costs.

Mr. LUNDQUIST. Minnesota has passed a comparable law, as I understand it, Minnesota didn't have a lot of actuarial basis for it. They started with a $5 million general tax input into the fund and a special tax on generators and those involved which will yield about $900,000 dollars a year. That will give us some empirical experience.

But in talking with the Minnesota attorney general's staff and the Attorney General when he was on this committee, they didn't really have that kind of information to do it.

Mr. MOLINARI. They protected themselves by putting a cap on what could be spent while they looked at the experience factor.

Mr. LUNDQUIST. That is right. I think one thing that is essential in this, although our committee didn't directly propose it, is to put some sort of sunset provision in, that after 5 years you look and evaluate the nature of it.

You don't want to build an institution such as Black Lung that has to be cut down to size in a decade or two.

Mr. MOLINARI. Thank you. I have no further questions.

Mr. LEVITAS. Mr. Light wanted to respond.

Mr. LIGHT. Another possible source of experience in this area would be the California experience.

They have had a compensation fund in connection with their State Superfund law for about I guess 2 years now and I have heard varying reports on their experience but I think that that would be worthwhile to find out what their claims experience is under that law.

The other thing is I have talked to a staff person in the Environmental Law Institute and I understand that they recently contracted with EPA to do a study of what happens to toxic tort claims in a couple of geographic areas. That is a study that just was undertaken by ELI for the EPA and that may be of interest to you somewhere down the road.

Third, there is also this study that you have—I would just remind you that there is the study that the Chemical Manufacturers Association is partially funding, the UAREP study, that may offer hints at the scope and dimensions of the problem.

The 301(e) group study, early in its deliberations asked EPA and the Justice Department to compile some information with respect to this aspect of the study and it was about the same time that this committee was undertaking a similar endeavor.

Mr. MOLINARI. I was going to guess that.

Mr. LIGHT. So we didn't get a lot. You will find appendices to the report showing what we were able to come up with. Professor Grad summarizes that in part 2 of the report.

Mr. MOLINARI. Thank you, Mr. Chairman.

Mr. LEVITAS. I have a number of questions, some are more specific, some which are more general but let me start with the specific ones.

Mr. Light, you indicated that Mr. Freeman had objections to the concept of punitive damages and you quoted his language about vigilantes—the sheriff takes over and the vigilantes stop.

But it would seem to me that the role of punitive or punitive-type damages is pretty well established in this area even where the sheriff moves in.

Let me give two that come to mind. In the antitrust field there is the possibility of criminal prosecution for violation of the antitrust laws; there is a provision for compensation, compensatory damages resulting from violating the antitrust laws; and there is in some instances a provision for treble damages which is a statutory punitive-type damage situation.

It is my understanding that the reason is that the standard for proof in a criminal case is not the same as it would be in the civil action; and that in order to provide effective deterrence for certain activities which violate the law the punitive damage or treble damage aspect is written into the law or developed in the common law.

Let me give you another example, a more classic example—fraud. In fraud you can be prosecuted criminally for certain types of fraud, fraudulent activity; obviously you can sue for compensation but you certainly can get punitive damages.

Why would it be inappropriate—why is it inappropriate in the appropriate factual situation in the case of toxic torts to provide a punitive damage or punitive damage-type remedy in addition to the other mechanisms?

Mr. LIGHT. First of all, it may or may not be the case that you would be able to seek punitive damages in the toxic tort case. It depends on what State you are in. Some States provide for punitive damages; some don't.

I think Mr. Freeman's concern in this connection is set forth in brief form in his separate statement in the Superfund report at pages 322 and 323 of the document that I gave Mr. Molinari.

He has several concerns in this area. One is that there is a strict liability doctrine, the doctrine for compensating injuries in the kind of situation where there may be abnormally dangerous activities or an ultra-hazardous substance. There seems to be a move, at least according to Professor Grad and the majority in the Superfund report, to a theory of strict liability in which the standard for awarding compensation is different than the standard you would apply to award punitive damages where you have outrageous conduct and so forth.

When both of those issues, the strict liability and punitive damage issues, are tried in the same forum there may be confusion as to which standards apply. That is one issue.

A second issue that he was concerned about is a situation where—it has occurred in the past in the product liability area—a situation where you have a lot of cases involving the same basic fact situation from the point of view of the defendant. The defendant has manufactured a product; the plaintiff alleges that it is defective in each of the cases and they seek punitive damages.

It is what I guess Jeff O'Connell, who was a member of the commission, would call a lawsuit lottery, everybody is in it for—every plaintiff's attorney is in it for—the possibility of the big payoff. There is also the possibility that in some situations you may have a big payoff for the first few plaintiffs that get to trial in the States that are speedier, and somewhere down the road you may find that there are limits to the amounts of insurance and assets of the corporation that you are suing. Later claimants thus are not compensated.

So there is a possible equity concern in connection with some of the mass tort cases.

The third strand in Mr. Freeman's thought is basically the one I summarized with that phrase "vigilantes have no place where the sheriff takes over" and that is the notion that in connection with some of these environmental statutes such as the Clean Water Act, or the Resource Conservation and Recovery Act, where comprehensive sanctions have already been provided—in fact, if the bill that is coming up for a vote soon, with respect to RCRA passes—there will be enhanced criminal and civil penalties. Under the proposed legislation a citizen would be able to go into court and seek civil penalties under RCRA just as he can now under the Water Act.

This is a law enforcement type function, a private attorney general type function in both cases with one exception, that is where does the award go? In one case, the citizen suit case, to the Government, in the other case the punitive damage case, it goes to whoever has brought the suit.

In the RCRA context you have a provision for awarding attorneys' fees to the prevailing party, so there is no real justification for the contingency fee system in that kind of operation.

So Freeman would put forth the position if he were here that there ought to be a separation of the law enforcement and punitive-type function from the compensation functions, first because of the different standards which are appropriate to awarding compensation under theories of strict liability, and theories for award of punitive damages; second, because of this possibility in the mass tort situation of a limited fund—which can be handled sometimes in a class action suit although our 301(e) group did not recommend class actions for personal injury suits—and the third reason being this notion that law enforcement should be handled by law enforcement personnel rather than private individuals who are in it for their own benefit.

Mr. LEVITAS. I am not sure you have answered my question because I was asking to contrast this to the other examples. Maybe Mr. Lundquist and Mr. Baron would respond.

Mr. LUNDQUIST. There is one very distinct aspect to punitive damages—I should say I am for punitive damages. I don't think that issue is resolved in the courts, particularly in the States. We have statutory ones that you referred to. But I think there is one significant difference in the area of toxic torts punitive damages and that is the latency period. You really are talking about punishing people 20 or 30 years later. In one case I know, the corporation involved, had in its largest shareholder in the State of California the California Teachers Retirement System. The corporation was being asked to be punished for conduct that occurred 20 or 30 years before. I find that illogical myself and it seems to be shifting things to where they don't really belong.

I would prefer to see a civil liability statute make corporate officials liable 25 years later personally. Then you would see the kind of conduct you want, I think.

So there is that problem. There is also the problem of the mass type of tort when the plaintiff with a relatively weak disability claim starts to hold up the system with a $3,000, $4,000, or $5,000 claim with the prospects of hundreds or millions in punitives. This creates an incentive that doesn't make sense and fouls up the system.

Third, as Mr. Light pointed out and the courts haven't gone along with this but one individual may ring the bell and collect everything. In the *Dalcron Shield* cases where there are thousands of people affected, Judge Spencer Williams created a class and said everyone is going to partake of any punitive damages. The ninth circuit, in logic that is not appealing to me, said no, you still have to come along and, under this analysis, the first ones will be lucky and I don't know what will happen to the rest of them.

The other point is that it does sometimes create problems of insurance coverage which again when you are trying to impose liability 20, 30, 40, or 50 years later, it creates a special problem.

Mr. Levitas. Mr. Baron.

Mr. Baron. I would disagree a little bit with Mr. Lundquist here. Punitive damages are absolutely essential particularly in this area. What we are trying to do is compensate victims, but also to determine misconduct. The bad effect of a big payout to one claimant is totally outweighed by the probability of deterring misconduct on the part of other actors. If the law was enforced I might feel differently about that. Unfortunately, vigilantes provide impetus to enforce the law to begin with.

I think those people should be permitted to have this tool to really affect social change on these companies.

As far as the latency period argument, that the companies are being punished for old acts, they committed those acts years ago. The corporation is an entity. The shareholders who now own the stock of that corporation have profited because of those bad acts. Why shouldn't they be punished for it? As long as we continue to provide for punitive damages we make a corporation's liability unpredictable which is exactly where we want it.

If they know what they have to pay they can institutionalize it and pass it on to the consumer. If they don't know what they have to pay, they are going to be much more careful about the way they conduct their business.

Mr. Lundquist. I have yet to see the corporate executive who says if I make a decision today which somebody is going to have to pick up responsibility for in 20 or 25 years, I get a short-term profit against an unknown liability 20 or 25 years down the road who doesn't seek the short-term profit. I just don't see—I wish I did—but I don't see a business responsive to that particular stick and carrot.

Mr. Baron. I would note for the record without wanting to say anything in detriment but Mr. Lundquist is counsel for Johns Manville Corp., which I think is the classic example of where conscious decisions were made by the board of directors in writing 20, 30, 40 years ago to do things that really should not have been done.

Yes, these corporations should be required to pay for them when they manifest themselves.

Mr. Lundquist. I have also handled plenty of punitive damage cases on the other side of that, and just to get in a jab at my good friend, Mr. Baron, essentially, my law firm operates under the auspices of his direction, we are retained in effect by the bankruptcy estate to sue the insurance companies, he is one of the people who is responsible and I trust approves of what we are doing on behalf of the many people affected.

Mr. Levitas. Let me——

Mr. Molinari. This is getting interesting.

Mr. Rowland. You and I are not going to get into that sort of thing.

Mr. Levitas. We are very fortunate, I want to make this a matter of record, to have Dr. Rowland on this subcommittee.

Mr. Molinari. Indeed.

Mr. Levitas. It brings an unusual perspective to our discussion. I am grateful for it.

Mr. Rowland. Thank you, Mr. Chairman.

Mr. Levitas. Those last couple of comments about the punitive damages and unpredictability raise some interesting questions to me which you may be able to respond to.

It is possible that we need accountants to respond to it. But my guess is, since I stopped practicing law actively, acquisition and merger agreements are written differently today than they were 10 years ago, and that generally accepted standards for accounting are probably now more focusing on potential contingent liabilities from environmental torts or environmental exposure.

We know of one situation already in this committee—which I won't identify by name—but in which a major Superfund settlement was made by a responsible party after years of conversation, because they were about to have a public offering, and their accountants or bond counsel would not quantify the exposure and they couldn't get an underwriter to take it, so they said, whatever the amount is, it is better than, as you say, the unpredictability, not knowing what it is, so they entered into a settlement agreement after years of discussions with EPA.

To what extent would a statutory solution to this type of situation, victims' compensation, provide a benefit to business, even by having some sense of certainty in terms of their exposure in situations of this sort?

Mr. Lundquist. I think it makes sense, but punitive makes it hard, first of all, it is against public policy to insure for that in most States. But you can quantify and obviously one of the interests of the insurance industry in our proposal was that it can quantify and can underwrite and provide compensation as kind of an internalized cost which, I think, is helpful to the business and hopefully to the people who get compensated.

My own view is that while punitive damage arguments are fascinating, they are kind of off to the side when we are talking about masses of people who simply are not being cared for. They should be regarded in a separate light.

Mr. Molinari. Would you yield?

Mr. Levitas. First, Mr. Baron would like to say something.

Mr. Baron. One of the things we did when we were on the Superfund, the attorney general of New Jersey, Jim Zasallie, was one of our members, and he made available to us staff members from his office and a couple of helicopters. We visited a couple of waste sites, and one example why we must leave punitive damages in these cases was a dump site owned by—I will change the name—I think the Burrelli Brothers was the right name. They had purchased a dump site, insured it for a known quantity, and then permitted it to be used for improper purposes, declared insolvency and after the suits came, the insurance people paid the money, and there was nothing left.

Without punitive damages, you won't be able to get to the Burrelli Brothers, you won't be able to get actually through the corporate veil and go directly to the source and deter this type of conduct.

It is absolutely essential that that remedy be left available.

Mr. LEVITAS. Mr. Molinari?

Mr. MOLINARI. I just wonder—do you want to respond, Mr. Light?

Mr. LIGHT. I just wanted to respond to Congressman Levitas' question about the possibility of a statutory solution increasing certainty, and that would be of an advantage to both the defendants as well as to plaintiffs.

I think we tried to deal with that in our prepared statement, knowing of your special interest in the Superfund statute.

I think that there is a possibility that it would be the case. In the Superfund Study Group, the group, by implication in its report and explicitly in the statements made in the Commission proceedings, rejected a Federal cause of action approach similar to the one that was set forth in the Senate Superfund bill in 1980, notwithstanding the possibility that there would be increased certainty if you had one uniform liability system.

The problem with that, one of the problems, is preemption. And there are two aspects to that. One is can you preempt State law or force the States, if you are worried about the burden on the Federal courts, can you force the States and the States alone to administer the newly passed Federal law without allowing access to the Federal courts?

The other aspect of it is that since you are limiting rights of the plaintiff or affecting rights of the defendant under State law by preemption by the Federal Government, won't that in the immediate future, the next few years, increase uncertainty?

I am not sure where Freeman comes out on this right now. I think he is a little unsure about where he would come out, except to say that the Superfund liability regime under sections 106 and 107 was very poorly drafted in 1980 for whatever reasons, and is a poor example to follow.

There are gaps in the statute, and that does create uncertainty. What issues are not resolved in the Congress are passed to the courts. You end up with a system which gets mired down in litigation when the stakes are high.

If you have a Superfund site, people want to resolve the situation, but if there are a lot of dollars involved, and nobody really knows what the law is on a particular issue, then you know, you probably on balance have a worse situation than you do if you just relied on previous State law.

Mr. **Molinari**. We discuss these questions in a theoretical vein, and you hear one argument on one side and you are persuaded by that and then somebody gives a counterargument, and you find yourself leaning in that direction. But when you start to look at actual experiences, I think the reaction of most of us is somewhat different.

I would like to share with you a couple of personal examples. Exxon, a rather big corporation. Exxon has a plant in New Jersey which, I found out through an informant, would retain the waste gases built up within the refinery for a period of up to 24 hours—that was the maximum period of time—and only release them, when possible, when the prevailing winds were coming toward Staten Island.

Now, I took that information and submitted it to EPA several years ago. They conducted an investigation and, indeed, found Exxon guilty of the practice. Exxon was fined $50,000, not a very large sum of money for Exxon, but when you consider the fact that Staten Island has one of the highest age-adjusted respiratory cancer rates in the country, your blood starts to boil a little bit. When you hear that, you wonder what is an effective penalty?

Obviously, you will never be able to prove that somebody got cancer because of that kind of occurrence.

Or take another situation, Mr. Chairman, something that floored me last week. Staten Island is across from a large petrochemical complex in New Jersey, and there are always complaints about different types of odors, cat urine, rotten eggs, and a whole host of other identifiable odors.

I took my congressional newsletter and utilized a questionnaire to pinpoint the experiences that my constituents had.

About a year or so ago, we sent the workup of that questionnaire's results to the State Department of Environmental Conservation and said, "This is what we learned from this process. Would you now try to do a better job professionally, as follow up, and see if you can identify who the real responsible parties are?"

Last week, I received a shocking report from the Department of Environmental Conservation of the State of New York. They traced back those specific odors to specific companies, again including some very large names—MERC company and others.

I was flabbergasted that we got such an excellent result where in the State was willing to identify the companies in those cases. Now, some of the odors may not be very harmful, but there are others that are, and you must speculate whether those companies would have known that they were guilty of, in some cases, releasing into the atmosphere some contaminants that were very harmful to the public?

What should we do about that kind of a problem? It is one that we have to consider, even if it is coming from one State and going to another State.

I ask you, what do you do in situations like this?

Mr. **Lundquist**. I have a couple of notions that would be, one at the Federal level, we should not permit as a nation the exporting of anything that you can't use in this country. That is a starting point which I don't believe has been done.

I think we are exporting problems abroad. You would like States to regulate themselves similarly so you don't tolerate one thing in one State that you can get rid of in another State.

That system of federalism, in a system of federalism, that is more difficult.

Probably the ultimate difficulty in these things, and it gets down to the reason why we ought to be eliminating toxicity, get the types of things they are using and hauling with the incinerator ships, because to make things benign is most important.

But the best example of what you cite now is I don't know what I would do if I lived in Tacoma, WA and worked there and had to now vote on whether or not to shut down that copper smelter which is the largest employer in town because they know it impacts on the lives of everyone there.

In my own—the point has been vividly made to me in looking at major industries in California because they have been shut down because of regulation, and the steel industry causing smog problem and all, seeing a picket line of workers in the plant carrying signs that say you can't eat clean air, which is a dilemma that I don't know quite how we resolve on any short-term basis except to compensate those that are hurt and get better and better controls over creating the problems.

Mr. MOLINARI. There is only one comment I would make to that: Anybody who had a member of their family who died as a result of those kinds of activities would not have any problem making a decision on how to vote.

Mr. LUNDQUIST. My experience with jurors is quite to the contrary in those cases. The older jurors say when we grew up, every carpenter had two fingers off their hand, the folks who lived near the plant or worked in the plant that my dad did, all knew they had silicosis because of things in their lungs. They accepted it as the way the world was in those days.

Indeed, these gentlemen here smoking are accepting the fact that they are, every time they do that, cutting off ascertainably probably 15 percent of their lives.

People make a lot of decisions that you don't expect. I found jurors, when you get that kind of situation before them, make that sort of judgment and again, it does not mean I think we should tolerate it.

I think we shouldn't. But I suggest to you that that is not necessarily a consistent objection.

Mr. BARON. Might I respond to that somewhat? I think Mr. Lunquist is a superb lawyer, because he is now talking about closing down the largest employer in a city as opposed to whether Exxon is going to release holding gases at night when the wind is blowing the other direction. They can't be compared, really.

My assistant Mr. Wodka, who used to be assistant safety director of the Oil Workers Union, reminded me that in 1969 and 1970, the OCAW provided testimony about holding those gases by Exxon in New Jersey, and that there was a problem that was identified then.

I suggest to you that fining Exxon $50,000 is probably a little less than requiring me to buy Mr. Lundquist lunch today. This is not an effective remedy. I further suggest to you that the effective remedy would be that if those citizens who are aggrieved and who have proof of the case of the problem band together and file a lawsuit against these companies, seeking punitive damages for these emissions, that they will stop.

Mr. LUNDQUIST. I agree with Fred on that. I didn't mean to take Mr. Molinari's example, I just tried to put the problem in a larger context.

Mr. LEVITAS. That is the way I took your answer.

Mr. LUNDQUIST. I think it is more of a dilemma, and I agree that you, Congressman, you and Fred were right in the Exxon situation or any situation like that. My comment was not meant to turn that around or condone that.

Mr. LEVITAS. I would also say, not in defense of the fact I smoke cigarettes, but——

Mr. ROWLAND. That is indefensible, Mr. Chairman.

Mr. LEVITAS. Also free-fall parachute jumping and hang gliding and a lot of other things I choose to do, it is another thing for Exxon to do it to me.

Mr. LUNDQUIST. I agree.

Mr. LEVITAS. Which is a lot of difference.

Mr. MOLINARI. I was just interested in Mr. Lundquist's acknowledging that as a practice that should not be tolerated. Would you sanction punitive damages in a case like that?

Mr. LUNDQUIST. That is certainly one way. That is a situation where I don't have much trouble with punitive damages. To defer current manipulative conduct they may be effective. My definition of punitive damages is basically outrageous conduct.

If I found out that I lived in your constituency and they were dumping stuff on me, I would be pretty outraged.

Mr. MOLINARI. Thank you.

Mr. LEVITAS. Let me go into another point with Mr. Light that Mr. Freeman had trouble with.

He suggested that there might be a good reason to force a choice to a potential claimant into going into tier 1 or tier 2 remedies.

Mr. Freeman expressed himself as being concerned that if you gave a claimant the opportunity to pursue both they would in fact use the tier 1 compensation as a means of financing the litigation in tier 2 that might occur.

Now without taking a position myself on this thing, but I think fairly characterizing what I understand Mr. Molinari's position to be, he would say precisely that is what ought to occur. You ought not preclude a person from exploring and pursuing full recovery simply because he doesn't have the economic means to do so, and that if a person is given living expenses and is compensated minimally that if the damages are actually greater than that that would be one of the great social benefits resulting from a tier 1 compensation to let this individual pursue tier 2 recovery.

I think I have characterized Mr. Molinari's view on that matter.

Mr. MOLINARI. Right.

Mr. LEVITAS. How would you comment on that?

Mr. LIGHT. Well, I think that in the Superfund Study Group if there was one issue on which it spent more than hours, indeed days, it dealt with this issue of the relationship between the tier 1 and the tier 2 remedies. And the debate is laid out within the 301(e) report which Mr. Molinari has, in some detail there.

On the one side there were those within the study group, for example at one end would be Professor Jeff O'Connell, who suggested that if we were really going to a no-fault type of system of compensation, for that class of claims in which you are providing no-fault compensation, you necessarily have to provide for an exclusive administrative remedy because of this problem that if you add to the costs of the administering the administrative system the costs of allowing the parties to also go in and seek further relief in the state tort system then the overall system will just be too costly to administer.

I think what was behind Professor O'Connell's notion—and he has written on this quite a bit and in fact he has a separate statement in the Superfund report you can look at—is that when you go to these administrative type systems allowing some kind of relaxed burden of proof either through a presumption or through some other mechanism allowing evidence that would not be admissible in a trial, then you are going to overcompensate. You are going to provide some relief to people who probably would not have recovered under the traditional standards of proof.

That cost has to be picked up somewhere and on balance as a cost control mechanism, you need to just prohibit, from O'Connell's point of view, access to the State tort system.

On the other side we have the proponents of the view of free access, which I take it is Mr. Molinari's point of view, which is that even though there may be some overcompensation in the tier 1 system, in that system we are talking about compensation and we want to get the dollars out. In the area of tort law we have other objectives seeking deterrence of evil or bad conduct, and that those are both valid purposes. So there is no real rationale for denying, putting up some barrier between the tier 1 and tier 2 remedies, in their view.

The Superfund study group itself adopted after much deliberation a compromise proposal which Freeman did not favor—he did not vote in favor of it—which was to allow access to the State tort system, but if the recovery in the State tort system, was less than 125 percent of what one got in the administrative system, then the judge would have the authority to assess costs against the plaintiff, both expert witness fees and attorney's fees.

I think that was probably on that particular day the only compromise that would have prevailed. At the last meeting of the group, a group of the attorneys, a subgroup, adopted a second compromise position. This is the position that Freeman adopts in his separate statement and also in a joint statement which is appended to the Superfund report. The four members that signed the separate statement being Professor Anderson, Professor O'Connell, Judge Breitel, the retired senior judge of the New York Court of Appeals, and Mr. Freeman.

In their separate remarks, Weyman Lundquist and Warren Spannaus, one of the attorneys general from Minnesota said that Congress ought to look at this as well.

Well, that proposal on balance would have shifted more claims into the tier 1 system by enhancing the benefits that were available in the tier 1 system to allow some recovery for what we might not—what Tony Roisman might not—call objective damages—for some limited pain and suffering award. In exchange for enhancing the tier 1 system this group of four—including Mr. Freeman—would have tried to systematize the payments for pain and suffering through some scheduling of benefits similar to procedures that operate, I understand, in some workmen's compensation systems in other countries.

That trade was made and then there was the barrier that would be created between the tier 1 and tier 2 system which was as follows: Instead of having an exit barrier, an after-the-fact determination of whether you can go into tier 2, you would have an entry barrier in which a plaintiff who wanted to go to the State tort system would, after having received his benefits in the administrative compensation system, go to a judge. And the judge would determine whether the evidence which was available at the time he had filed the administrative claim and the subsequent evidence which he had discovered, demonstrated that there was a reason to allow this guy into the tier 2 system.

He could allow that. There could be an exception made in the specific circumstances of that individual. But on balance the normal process would be one in which the claimant would choose a quicker, more limited kind of benefit in tier 1 including some pain and suffering award, foregoing the punitive damage claim, for example, because he might not see that there was that kind of outrageous conduct in the case. So he would go for quicker recovery; or go for the tort law recovery with the higher risk but with the possibility of greater recovery at the end of the line.

So that is where Freeman came out. It really was not a pure binding election there. There would be exceptions and it became an entry rather than exit barrier approach. In fairness to the study group I think the proposal in its ultimate form, and as pictured in the joint statement at the end of the report, was not considered because of time. The study concluded 6 months after the legislation called for it, and it was time to get the report out.

Mr. LEVITAS. Let me ask you this, Mr. Lundquist.

You raise the question of the problems associated with long latency periods. We have had a good bit of testimony about that. That creates a whole host of problems. Not only the problem of the exposure of the responsible party and potential defendant, but also enormous questions as to proof, cause and effect, and who is around, not just the defendant but the plaintiffs, that whole question.

It is particularly true in the question of toxic chemicals—carcinogens, mutagens and things of that sort.

How do you feel that this subject of long latency, given the problems of proof deficiency, or impossibility, on the one hand; and the open-endedness on the other hand? How should it be addressed in terms of proof, evidentiary proof, presumptions, and statute of limitations?

Mr. LUNDQUIST. To reverse the order, the statute of limitations I don't think is troublesome. I think if there is one thing that myself and every member of the committee conceded is the statute of limitations begins when you find out, reasonably should have known. I think that there is no problem with that.

Mr. LEVITAS. Known of the injury?

Mr. LUNDQUIST. The fact you are suffering——

Mr. LEVITAS. Not exposure.

Mr. LUNDQUIST. That is right. Not the exposure, the injury. We provided 3 years thereafter within the system that we proposed.

Second, I think this is where the idea of presumptions is extremely important and it is something we don't know enough today to define these precisely. Indeed I have tried to, in evaluating this to talk to scientists not retained by plaintiffs or defendants and indeed in California we have some that are prohibited from taking compensation, those are members of the university system. I have sat down with particularly Mr. Ed Schmuckler, head of pathology at the University of California, San Francisco. He is a leading pathologist nationally known. There are very few areas where there is the precise definition you could start out with today and again any individual might have a lot of problems to do it.

So there we dealt with the situation if you have exposure and if you have an injury that comes from that exposure that is enough. Now, to get to that level, presumptions are based on something happening more likely than not. They are based on credible evidence. Obviously in the initial instance we are not going to take the common cold and the fact somebody caught a cold and worked in a wet, open building. That isn't the sort of situation we are talking about.

But we are talking about a known toxic and an injury that would flow from it and you presume that somebody—somebody in tier 1 has the injury or disease that does that. Then you have to evaluate the disability.

You have that. That is one of the presumptive factors.

The other thing you do is that you allow the Federal Government through the development of toxic guidelines if you will, toxic documents I think we called it, to make tests and say that in this industry if you are exposed to certain things it is known that this exposure will cause a disease and you will be able to use that by way of proof and use that level of scientific knowledge in the case so you don't have to go to the individual proof.

The reason I think this is so important and this speaks to a personal view of mine, I think the system has failed the victims in that the transactional costs have really benefited the lawyers. On the plaintiffs side you have to figure they have gotten 25 percent to a third. The system has paid on the other side, I suspect the defense bar across-the-board collects as much as the plaintiff's bar. It is an enormously expensive thing for injuries which generally have not shown themselves as yet to this day to be severe.

Again I say that because we are talking about the mass of claims now and I am not saying that the person who comes down with cancer and can establish it, doesn't have great injury but we leave that to the existing system. What we were concerned with was to get a quick, efficient and economic system. That was the reason for the presumptions and the approach taken for eliminating those transactional costs that underlie that sort of approach.

Mr. LEVITAS. Now, Mr. Baron, let me turn to you for a moment. I am sure I am oversimplifying but essentially you think the existing tort system works with some modifications and finetuning. Yet I think it is fair to say that this whole question of toxic torts, environmental health damage, the whole business of chemicals and people and environment is a relatively new phenomenon. I grew up in an era when we used to listen to the DuPont Co.'s radio program "Better Living Through Chemistry."

If I said that to my kids today they would scoff and laugh at me even though there is still truth in it.

In every major period of history, either our technology has changed or our communications and transportation have changed, or our commercial institutions have evolved, and the law has created essentially new systems to deal with them; the whole evolvement of the common stock corporation to deal with the massive investments of the mercantile period, and the expansion into the new world during the colonial period; Lord Mansfield's development of commercial law concepts to deal with the whole new system of interchange of that period; the question of workers compensation supplanting the fellow servant doctrine that I remember; the development of a concept of equitable mortgages to protect people who were being foreclosed in an era that you had seen this tremendous mushrooming of middleclass land ownership.

Buick v. *McPherson* was in the 1930's, wasn't it? We didn't get a system of negligence evolved until the 1930's because we had a new system, and in recent years the whole idea of no fault insurance. I was in the State legislature when we passed our first no fault insurance. So the law has revolutionized itself to meet with revolutions going on in the economy and in the technology.

Now, what is wrong with saying, look, we have now discovered toxic torts, chemicals, we have problems of proof, we have problems of long latency, we have problems of cause and effect. We have these variety of problems and notwithstanding the fact that we still may not have the ultimate proof in terms of certainty scientifically. I think if you asked the members of this panel who have been listening to testimony for 2 years now, that we would say there is a problem out there and people are suffering.

Why shouldn't we develop a no fault type system for compensation of these victims and recognize, like in the case of workers compensation, it is a trade-off, or no fault insurance, it is a trade-off? You either provide an efficient system of some degree of certainty of compensation or you bet on the outcome, that there is a good system out there, that the effective lawyer and the skilled expert witness can capitalize.

Why shouldn't we simply go to a sort of no-fault system or workers compensation system?

Mr. BARON. For the same reasons we have not with all the other problems you have described.

The *Buick* case threw out privity, this was done by the common law. The California Supreme Court back in the early 1960's adopted strict liability. That spread. It was done by the common law.

Comparative negligence systems in many States have been implemented by the common law in response to a problem.

Most all of the case law now on the statute of limitations in latent disease cases adopt a discovery rule, again done by the common law.

I believe that the common law is a moving flexible body of law that will deal with these problems in an efficient manner and will permit victims to be able to really and truly have their day in court, where they can receive full compensation without creating some nature of an administrative monster that is going to gobble up the funds in the administration of the system that essentially provides very sparse benefits anyway.

The workers compensation system, unfortunately, is the classic example of that because, as probably everyone in the room knows, for a serious injury case, workers compensation benefits just about anywhere, with some limited exceptions, are inadequate. They overcompensate people with a sore back syndrome or cervical strain, but a victim who has a serious injury doesn't receive adequate compensation through workers comp.

The only way they will truly be compensated will be through movement of the common law which is occurring now. There are exceptions. New York is one of two States where the highest appellate courts have refused to adopt a discovery rule for the statute of limitations. The other 42 State high courts have adopted one in one form or another, and, definitely, legislation is necessary on that issue in that State. That doesn't mean we should throw out the whole tort system.

I believe generally it will evolve to a very workable, efficient system.

Mr. LEVITAS. Well, you lead me into my last question unless either Mr. Light or Mr. Lundquist wants to comment on that, but my last question is a more general philosophical question which I address appropriately to my brother lawyers.

One of the problems and criticisms I have of the 301(e) study is that it was essentially a lawyer's study. And I do not denigrate that aspect of it. The amount of expertise and knowledge and insight into the whole subject matter, not just the legal side of it, is irreplaceable. There is no other place you can go and find that much broad expertise not just from the fee-getting-fee earning business, but just from involvement.

Yet the problem of victims compensation, toxic torts, in today's world is not just what is the best legal remedy. It really isn't. It is a question of spreading the social cost of the world we live in, and we are going to continue to live in, and the social cost to the people who will pay for it and that means everybody, because we are all receiving the benefits from it.

For example, people who are suffering from PCB exposure are people who also benefited from the electrical power generation that came about as a result of that insulation material. Rightly or wrongly, I am just saying we are not talking about the traditional situation.

There may be other important significant contributors to how we resolve this matter. So, I suppose what I am asking is how do we divorce the vested interests of the plaintiff's bar, or the defendant's bar, or the insurance industry and their legitimate interests, from the legitimate social interests.

Mr. Rowland commented to Mr. Molinari—if you don't mind me saying?

Mr. ROWLAND. Go ahead.

Mr. LEVITAS. He said: "A lot of this sounds to me like just another way for lawyers to make some money one way or the other, you know, defending these cases, being plaintiffs' attorneys, and so on, and that is not what this ought to be about."

That is certainly not where we are coming from. So how do we deal with it? I realize this may sound like a nebulous question, but believe me, that is the last question that has to be answered before we make decisions, whatever they may be.

So I wonder if any of you wish to comment.

Mr. Lundquist?

Mr. LUNDQUIST. First of all, among the things that I pointed out that we need are—I had a list of things that if you were looking to the future, what we really need and what I feel is, lacking to some extent, were independent scientific medical-legal-insurance, actuarial people to give us the dimensions of the problem.

I really don't think that we have complete understanding of the dimensions of the problem. Further, we probably need philosophers because the person who dies at 77 and has lost 5 years of his life but when he was born had a life expectancy of 51, raises philosophical questions in there. So, we really need that input.

Now, what business do we have as lawyers in this?

I think one of the things that lawyers do or try to do is communicate. To the extent we communicate diverse points of view from science, from business, from insurance, from personal injury clients, we do bring ideas which reflect the different interests of others. So I think to that end we are helpful. But I am not satisfied that we have come to the solution.

Indeed, if I might stand up, I am concerned and I have thought about it a lot. Perhaps we have done what the fellow did who wanted to buy a suit. He didn't have a lot of money and he went to the store and said, "I want a suit," and the salesman said "I got this one." He said "Put it on. That looks nice."

How much is it?"

He said "A hundred dollars. That is a terrific suit."

"I'll take it for a hundred dollars. But this pants leg is a little long. Can you alter it?"

He said "No, we don't alter suits that cost only a hundred dollars. Just put your hand in your pocket and hold it up and it will be all right."

The guy said "All right, but the waist is a little loose."

He said "Look, stick your hand in your jacket and hold it up and it will be fine."

The guy said, "Look, the shoulder is falling off."

He said "Get your chin over there and hold it." And the guy buys the suit. He goes out down the street past two elderly ladies and one says "Look at that poor man, all crippled up like that." The other said, "Yes, but it isn't all bad, the suit fits beautifully."

End of comment.

Mr. LEVITAS. Mr. Baron?

Mr. BARON. Essentially my profession, the plaintiff's bar has been maligned probably as much as any group in the world and probably for very good cause under some circumstances.

Quite honestly, I would far prefer handling aviation cases or divorce cases if there were no toxic chemical cases to be involved in. I think that too often we are judged only by our economic interests in the case.

There are many of us who practice this type of law who feel very strongly about it and who feel strongly that there are two purposes to be served here, certainly victim compensation is No. 1. But No. 2, I learned in law school from Dean Keaton years ago that the purpose of the tort law was to deter conduct and unless and until someone comes up with a better way to deter conduct I believe that the tort system is the only functional way to do it.

We are dealing with the conceptual and practical. Conceptually it would be nice if the victim walked in, the doctor said yes, you have this disease and he was given a check and off he went and there was no transactional cost. That would be a wonderful system.

Unfortunately, that is a pie-in-the-sky thing. It is not going to happen. The Black Lung Act has proved that over and over and over. It is not a situation that is feasible.

There is a need for attorneys to handle these cases. There are bona fide disputes. No one has come up, including our group who studied this issue thoroughly, with a better way of doing it that actually in practicality works. That is the bottom line.

There are wonderful concepts of how it should occur, but when you get right down to it, how do you serve these two functions, we can't find a better way to do it.

Mr. LEVITAS. What do you think about the suggestion of simply shifting the burden of proof to the defendant?

Mr. BARON. I would like to speak to that because I think everyone on the group was very amazed at my position when I took it. They assumed I would like to have a presumption in favor of compensability in any case where it is tier I or II. My practical experience, however, teaches me otherwise. If you develop a presumption that chemical A causes disease B and C, and then your claimant comes in and he has disease D. You have really lost the whole shooting match because the judge or whoever the trier of fact is going to be says, hey, the presumption is that this chemical causes B and C, you have D, it can't be related.

It is a double-edged sword. It is a difficult proposition. If we knew all there was to know about these toxic chemicals and about their effects, then perhaps that would be a rational approach. But the fact of the matter is we don't and because of that fact I think that the presumption probably hurts the victim more often than it helps.

Mr. LEVITAS. Mr. Light, if you would take that last question to which Mr. Lundquist and Mr. Baron responded, that rather general question I asked, we will get it for you from the reporter so I won't have to repeat it, if you would ask Mr. Freeman to respond for the record I would be grateful.

[The information received follows:]

HUNTON & WILLIAMS,
Washington, DC, August 16, 1983.

DEAR MR. LEVITAS: Thank you again for your courtesy to my associate, Dr. Alfred R. Light, at your hearing of July 26th and your kindness in making my prepared testimony a part of the record despite my unavoidable absence. I have had an opportunity to read the rough transcript of those hearings and will respond to your invitation to offer a few thoughts on the concerns you, Mr. Molinari, and Dr. Rowland expressed at the hearing on July 26th about how we might "divorce the vested interests of the plaintiff's bar or the defendant's bar or the insurance industry and their legitimate interests, from the legitimate social interests." A fear expressed was that toxic tort litigation may become "just another way for lawyers to make some money," especially in light of the increasing number of attorneys in this country.

First, let me say that I concur with your view that the Superfund Section 301(e) Study was handicapped by being composed only of lawyers. Judge Breitel and I in our separate statements in the printed report pointed out the need for broader perspectives from outside our profession. The study suffered, as do most of the law review articles in this field, from that "lawyers only" limitation of perspective. But we suffered under other limitations as well. As Dr. Light pointed out in response to a question from Mr. Molinari at the hearing, the Study Commission also suffered from the same difficulties which this subcommittee recently experienced in trying to obtain information from EPA and the Justice Department as to the scope or dimensions of the hazardous waste exposure problem.

But, on balance, I think the 301(e) Study still provides you a useful first step to thoughtful consideration of the compensation issue. What is now needed is for Congress to insist that others outside the legal profession come forward with information directly relevant to the scope and dimension of actual or potential injuries and how persons actually injured are or are not being compensated under the present system. We also need some sort of objective evaluation of the efficiencies and inefficiencies of the present system and porposed changes to it. The recent Rand Report showing that only $1 out of every $3 paid out in connection with the current number of asbestos related tort claims goes to compensate those injured illustrates the need for equivalent analysis in this area of tort law. But to urge caution does not mean that we should turn our backs on the concerns that have been expressed in these areas and be content with the status guo. Quite the contrary. A growing number of people are concerned with these problems. Various studies are underway involving lawyers and non-lawyers that should permit a more reliable assessment than is possible given the current state of knowledge. They are also seeking what may or may not be the best way to improve or change the present system. For example, one of the most interesting projects, jointly sponsored by the Yale Law School and the ABA's Ad Hoc Committee on Tort Law Reform, is a conference of lawyers and non-lawyers in the Spring of 1984. Its objective is to see how the present system is actually functioning and then to see if reforms would be efficient and equitable. The outcome of this and other studies now underway will be directly relevant to where change is needed and whether the final changes would actually make things better rather than worse.

With this preliminary caution, from my perspective as a member of the Superfund Section 301(e) Study Group and my subsequent study and analysis, there does appear to me to be some general principles, which if adhered to in a federal legislative proposal, would make a compensation system serve legitimate social interests to a greater extent than the present system.

1. In areas where there are major limitations of scientific and medical knowledge as to (i) existence of injury, (ii) extent of injury, and (iii) causation of injury (i.e., the nexus between exposure and injury, particularly where there may be multiple causes), any federal legislation should assure that the principles and procedures governing determinations of injury and causation be fair and objective. That fairness and objectivity must be perceived by both those injured, on the one hand, and industry and consumers, on the other. We should not have a tilt in either direction. A tilt in one direction would be unfair to victims; a tilt in the opposite direction would impose economic burdens which are not only inequitable but which amount to a misallocation of resources which the nation can no longer afford.

These considerations argue in the first instance against any statutory presumptions. There is a line to the effect that it is not what we don't know that hurts so much as the things that we know that are not so. Freezing into a statute a set of presumptions which may well be disproved, at least in part, by later advances in knowledge is highly unwise. The Black Lung experience on presumptions is instructive.

I believe it appropriate to provide for the preparation of health effects documents which might be considered in a proceeding to recover compensation. If such documents prove useful, they could reduce substantially the waste apparent in case-by-case repetitive adjudication of the same scientific or technical issues. This preparation must be subject to three essential safeguards against abuses which only benefit lawyers and other intermediaries.

First, the documents should be prepared by a body totally independent of the agency or agencies charged with regulatory functions or with the function of administering compensation. An appropriate body to prepare such documents might be the Center for Environmental Health in the Centers for Disease Control or the National Institute of Environmental Health Sciences within the National Institutes of Health.

Second, such documents should be prepared and issued in accordance with a rulemaking process governed by the Administrative Procedure Act and should be subject to judicial review under that Act.

Third, the weight to be accorded such documents should not be prescribed in advance but should be determined by the agency administering compensation on the basis of the document's own internal quality and of its relevance to the circumstances of the particular claim.

2. Any Federal statutory remedy should be exclusive and should supersede all concurrent state tort law rights and remedies, particularly if the statutory remedy is to provide for recovery of non-economic damages. Different and overlapping Federal and state law rules as to liability (causation, fault, defenses), statute of limitations, punitive damages, and measure of compensatory recovery would lead to delay, confusion and waste harming both victims and defendants, and benefiting only lawyers whose need is based on such unnecessary complexity.

3. A statutory remedy, particularly if it is to dispense with proof of fault, should put reasonable controls on recovery for pain and suffering and on other types of non-economic, subjectively determined damages. In particular the Federal administering agency should be called upon to develop a uniform schedule prescribing ranges for types of non-economic recovery, along the general lines suggested in the joint Anderson, Breitel, Freeman, O'Connell Statement in the Superfund § 301(e) Report.

4. There should be reasonable controls on litigation expenses. This could involve replacing the contingent fee with a system for separate award of a claimant's attorney's fee above the amount of recovery and a concomitant prohibition against applying any part of the recovery to legal fees. Consideration should also be given to mandating settlement offers, to financial disincentives for groundless claims or defenses, and to financial disincentives for unreasonable litigation tactics (claimant or defense).

5. A statutory system of no-fault recoveries should not be coupled with conventional tort litigation for punitive damages. The Solid Waste Disposal Act currently provides both criminal sanctions and civil penalties with a citizen's right of action to seek injunctive relief. This statutory punishment/deterrence system should be exclusive and should expressly supersede any common law right of action for punitive damages.

6. Claims for compensation under the system should be directed to the owner/operator of the facility at the time the exposure occurred; the owner/operator should be solely liable for payment of such claims ("channeling"). The owner/operator should be required to prove financial responsibility to meet claims, through liability insurance or equivalent. The aggregate liability of the owner/operator should be limited to the required amount of financial responsibility. Any owner/operator's right of recourse against generators or others should be based on rules of comparative responsibility to be determined and applied as a matter of Federal law, if there is to be such a right of recourse. The Federal Government should be responsibile only with respect to (i) so-called orphan sites or (ii) sites where post-closure financial responsibility coverage has expired, or (iii) amounts above the required level of financial responsibility. Adoption of this proposal could substantially reduce the aggregate social costs of the system through reductions in legal costs and elimination of duplicative insurance premiums.

This system would (i) minimize Federal involvement in defense of claims, (ii) assure private financial responsibility to meet claims, (iii) permit workable private insurance arrangements by avoiding pyramiding of coverage through rules of joint and several liability, (iv) to the extent practicable, assign responsibility to the particular activity causing the harm, (v) involve use of Federal funds only where private sector resources are not available at all (such as orphan sites) or where those resources have been first applied (up to the level of required financial responsibility), and (vi) substantially reduce aggregate social costs of the system (which would ultimately be borne by the general public once the system is in place).

7. A number of factors indicate that any such system be administered through an administrative agency rather than through the courts. State agencies, either worker compensation boards or other bodies, should be preferred if they qualify under Federal guidelines. The guidelines should be developed by a separate office within a Federal agency that is not "mission oriented" (such as EPA, for example). That office should assume the claims administration responsibility in any state where a state agency has not applied or has not qualified.

8. Where a state agency administers claims, appeal should ordinarily be through the state courts. Federal courts should have appellate jurisdiction only where the federal agency finds that the state agency was in error or where the federal agency has administered the claim.

I should emphasize that those ideas represent my current preliminary thinking as to a more efficient compensation system. By decreasing the need for lawyers and other intermediaries, it should substantially reduce aggregate transactional costs and, at the same time, assure that a higher percentage of the total social costs of the system actually go out as direct payments to compensate those injured.

Sincerely,

George C. Freeman, Jr.

Mr. Levitas. Dr. Rowland?

Mr. Rowland. Thank you very much, Mr. Chairman.

I do not like to find myself in an adversary position with attorneys, but sometimes I do, even with my colleagues here. But we are all looking for the same thing, I think, we want to compensate those people who have been harmed by dangerous chemicals and I believe there are people out there who have been harmed by these chemicals. I do not know at this point how severe the damages have been, what the long-term effects will be. There are many, many things that are undetermined.

I am particularly interested in the study group and the Superfund idea and the things you talked about, Mr. Lundquist, as a possibility of dealing with the problem.

Let me say why I am concerned about it. I know, as a physician, that we have been saying in this country for many years we need more doctors and this would make the quality of health care improve and costs come down.

So we have more physicians and we are going to get even more and just the opposite of that has happened. There are doctors out there doing things they ought not to do, because there are too many of them, and they are hungry.

So the quality of medical care is coming down, and the cost of medical care is going up. I don't impugn or even question the motives of the toxic tort litigation group because I don't know.

As you say, this is a new area of law. Toxic effects of chemicals, as we look at them now, is an entirely new area. Also, we talked about lead poisoning and how long we have known about lead poisoning. We have known about it for a long time.

In fact, I think we may have established that the Romans had lead poisoning and that may have been the cause of the fall of the Roman Empire. But the fact is, we are learning more and more about lead poisoning.

At one time, we thought it was neurotoxic; we are learning that it causes mental retardation. We are learning more and more about it. So I think that it takes a long time to really determine the effects of these chemicals on individuals.

The toxic tort litigation group—and we talked about this going out—causes me a great deal of concern because I am concerned that more and more suits may be filed in the coming years. It doesn't cost much to file a suit, of course.

But a suit does cause a great deal of anxiety and it can cause a great deal of cost and this cost will simply be passed along to the people that receive whatever it happens to be that this company is producing.

In fact, it could go to the point that the company could be put out of business with a lot of dislocations. There are all kinds of things that could happen in that area. Things are getting cheaper, you even refer to the fact that while one person said it might cost $200,000 to get a case together, you indicated it could cost much less than that, and maybe if we did this in large numbers, it would be even cheaper than that so far as getting medical examinations and Don and Mr. Roisman earlier this morning said that, I believe, that the faster gun is the one that wins sometimes.

So, I have a lot of concerns about what is taking place in this area. I want some compensation for the people who have been injured, but I think it is going to take a long time to prove that, and in the meantime, perhaps we need to look very closely at what has been taking place with Mr. Lundquist, not ruling out the possibilities of the victims' compensation law.

I think we need to continue to look at many things. I just wanted to express my feelings about this, Mr. Chairman, and any response that anyone may have, I would be delighted to hear it.

Mr. **Baron**. I would like to respond briefly, if I might, Mr. Congressman.

As far as forming groups of lawyers handling this, the purpose was to solve the problem Mr. Molinari pointed out. There are not enough lawyers now who are familiar with these problems, and when a client comes into your office and you know nothing whatsoever about the problem, you have got to either find somebody who does or learn about it yourself and, therefore, that is the reason for this group.

There is no profit motive involved as such. There is a professional efficacy motive involved in teaching other lawyers how to deal with these types of cases so they can recognize and handle them.

Second, I am glad it doesn't cost much to file suit. I disagree with the Chief Justice. I would prefer seeing more lawsuits filed for valid claims. It certainly keeps people off the streets with guns and knives.

If people have been injured and they can prove in court who caused their injury, they should be entitled to access to the courts. We shouldn't create barriers to keep these people from asserting the rights that they have in our country.

Finally, if companies are put out of business because they have harmed other people and because they have to pay for that harm, so be it. I don't think that there is anything that is so absolute that it should never be attacked.

If a company is engaging in practices that cause a substantial harm to other people, then indeed they should pay for it. I firmly believe that.

Mr. **Rowland**. Let me make one comment about what Mr. Lundquist said, that after it, why more people try to get on the bus than before the wreck. I appreciate your statement.

Mr. **Lundquist**. I think that—I said this last week to the ninth circuit, judicial circuit. I think lawyers are part of the problem. The explosion of big law firms—and I come from a big law firm—is due to the fact that lawyers get paid by the hour. It is thought the more you can do on behalf of the client, the more hours you put in.

I do think that that element is there. I think that the whole notion of too many lawyers from unaccredited law schools, indeed someone has said that in California, with our current rate of admission by the year 2007, everyone in the State will be a lawyer.

That leaves us only ourselves to sue. Obviously, that isn't a good thing. At the same time, I think lawyers and particularly the jury system have functioned very well. We have caused a lot to change, and I think we need to preserve that.

But my own philosophy in this two-tier approach was to try to get rid of some of the legal costs on both sides, defense and plaintiffs, and get the money to individuals. I think if you could pull lawyers out of that, or limit the fees on either side by way of plaintiffs of defense, you are doing a good thing. You should do that.

So, lawyers are part of the problem.

The other thing is, I keep coming back to it, my 30-year history with environmental movements from living in Alaska to California to Massachusetts, is to prevent things. I think acid rain or any type of mass pollution, this is where we ought to be looking, because we have a problem now.

Hopefully, in 20 years, we won't be looking at the same problem.

Mr. LEVITAS. Thank you very much.

I should really send each of you a copy of my Law Days speech this year to Emory University. You have all addressed it in your final comments. There is a Parkinson's Law at work in the legal profession, the amount of business expands to subsume the amount of lawyers.

I know you have all heard the one about the lawyer who got out of law school in a small town and was starving to death. A few years later, he saw a friend of his, a lawyer who had been starving to death, who had a nice suit on, and looked prosperous driving his BMW and the friend says, "How is it you had such a great turnaround economically?"

He said, "Another lawyer moved to town." And until then, he didn't have any business. I am sure you have all heard that story.

I think there is a real problem. This is part of it. This is what Dr. Rowland is talking about. That is why I was so pleased he mentioned that. There is a feeling in this new area of the law we are addressing where the lawyers come out on it.

I don't just say that to plaintiff's bar at all, really. It is a question of "Lawyer, heal thyself," I suppose, and we as a profession have to be worrying about that more and more as a profession, which we are still, I suppose.

But anyway, gentlemen, I can assure you that your testimony has been most provocative as well as enlightening. I learned a great deal today from what each of you had to say, and the differing views that were so well and articulately expressed by each of you will, I think, give us a basis for a much better understanding of this whole question of toxic tort and victims' compensation as we look to the future.

I have a feeling that your contribution will help make our final report and recommendations to Congress of benchmark value.

I want to express my appreciation to you.

Tomorrow, we continue with these hearings. We have Khristine Hall, cochairman of the Toxic Program of the Environmental Defense Fund; Leslie Cheek, III, vice president, Federal Affairs, Crum and Forster Insurance Cos.; Sheila Birnbaum, associate dean and professor of law, NYU Law School; and Dr. John Beljan, representing the American Medical Association.

Mr. Rowland, maybe you would want to come back and watch that?

He is going to explain the position of the AMA on dioxin, as I understand.

Mr. ROWLAND. I will be here.

Mr. LEVITAS. So, tomorrow, we have a very full agenda, and I hope the schedule on the floor of the House will permit us to get through it with a minimum of interruptions.

Again, gentlemen, thank you very much. I appreciate your being here.

The subcommittee stands in recess until 10 a.m., tomorrow morning.

[Whereupon, at 3:50 p.m., the subcommittee recessed, to reconvene at 10 a.m., Wednesday, July 27, 1983.]

HAZARDOUS WASTE CONTAMINATION OF WATER RESOURCES

(Compensation of Victims Exposed to Hazardous Wastes)

WEDNESDAY, JULY 27, 1983

House of Representatives,
Subcommittee on Investigations and Oversight,
Committee on Public Works and Transportation,
Washington, DC.

The subcommittee met, pursuant to call, at 11:10 a.m., in room 2167, Rayburn House Office Building, Hon. Elliott H. Levitas (chairman of the subcommittee) presiding.

Mr. Levitas. The subcommittee will please be in order.

First of all let me apologize to everyone here for the late start of these hearings. Congressman Molinari and I were involved in preparation for some other matters that had to be done this morning before we could begin these hearings and it was unavoidable. I express our apologies to everyone who may have been inconvenienced by it.

We are very much looking forward to the testimony today. Yesterday we heard from a panel of attorneys as well as a former official of the Justice Department who has been active in the area of litigation in the toxic tort field. It was a hearing that demonstrated once again that there is great diversity of opinion and approach in this entire matter. At times acrimonious.

But there still seems to be a realization that we are talking about a new area of law and a new area of concern, of public policy concern, that requires the attention of Congress to address in an objective way, based upon a full record of facts. That is where we begin today, to continue to make that record.

We will be hearing from Khristine Hall who has had experience in the field of victim compensation on behalf of environmental organizations, and will describe the problem of victim compensation as viewed by the environmental community. Her specific activities in this area, in fact I think I recall reading an article or a panel that you participated in on environmental matters not too long ago.

Following Ms. Hall will be a panel of individuals reflecting the views of the insurance industry. Since the whole question of victims' compensation and the problem of toxic tort as well as hazardous waste has created an entire new dimension for insurance carriers, we feel it is very important to shed some light on the subject from that perspective.

Then we are finally going to hear today from Dr. John Beljan appearing in behalf of and representing the American Medical Association. He essentially will talk about dioxin, agent orange, and the AMA's position on this matter about which there has been a great deal of controversy swirling for a number of reasons including resolutions and rescission of resolutions that occurred at AMA's recent meeting in Chicago.

I am looking forward to a very interesting day of testimony.

One other point; the House will be going in session at noon today. My guess is that we will have interruptions during the course of the day and they are to be expected. It is par for the course. It is also possible—and I will confer with my colleagues later—that we will take a short break for lunch at some appropriate time.

With those few comments I inquire whether my colleague, Mr. Molinari, has any statement.

Mr. **Molinari**. No, Mr. Chairman, thank you.

Mr. **Levitas**. Mr. Rowland.

Mr. **Rowland**. No, Mr. Chairman.

Mr. **Levitas**. If not, may I ask you to raise your right hand, Ms. Hall.

[Witness sworn.]

Mr. **Levitas**. Thank you very much, Ms. Hall.

We appreciate your being here today. I would request of you and the other witnesses to confine your opening remarks to approximately 10 minutes so that we can get into questions.

We welcome you and look forward to your testimony. You may proceed as you so desire.

TESTIMONY OF KHRISTINE L. HALL, COCHAIRPERSON, TOXIC CHEMICALS PROGRAM, ENVIRONMENTAL DEFENSE FUND

Ms. **Hall**. Thank you, Mr. Chairman, and members of the subcommittee.

My name is Khristine Hall, I am a staff attorney with the Environmental Defense Fund. I thank you for the opportunity to give my remarks today. I am with EDF's Toxic Chemicals Program which for the last 10 years or so has concentrated primarily on regulatory aspects of toxic chemicals.

During the course of that work we have come into contact with many people across the country and this contact has led us to be concerned with victim compensation, that is compensation for people who have injuries resulting from exposure to toxic chemicals.

Over the last several months I have had occasion to meet periodically with members of other environmental organizations, with citizen groups from across the country and other people who are also interested in the issue of victim compensation. I can unequivocably state that the environmental community strongly supports the need for the victim compensation legislation. We want to see the glaring loophole of Superfund plugged wherein damage by toxic chemicals for natural resources is compensated but people injured by toxic chemicals are not.

Our support for victim compensation legislation is premised on the fact that there are real victims and secondly that there are insurmountable legal barriers preventing them from being compensated.

Although I know you have had panels with people who are victims, I would also like to add a few more examples to the record. These are examples that have come to my attention in the last 6 months or so.

Out of 112 blood samples taken by the Center for Disease Control from people living in dioxin-contaminated areas of Missouri, all 112 samples showed biomedical evidence of liver dysfunction. These are very sick people.

The rate of heart defects in infants born to mothers in San Jose, CA, who consumed water contaminated with trichloroethane is significantly higher than the rate of such defect in the general population.

Third, many children living near a lead smelter in Dallas, TX, have severely elevated blood lead levels, well above levels that the Public Health Service defines as lead poisoning.

Fourth, scientists have found that children in Michigan with a high body burden of polybrominated biphenyls in their fatty tissue have decreased intellectual capacity as measured by school performance.

Lastly, a significant number of the rural population of Hardeman County, TN that drank chemically-contaminated drinking water have symptoms including liver damage, enlarged livers, or optic atrophy, early onset of blindness.

These are a few examples, it is not a complete list. A complete list is impossible to compile since we have only begun to research the issue of injuries produced by toxic chemicals and because many of the diseases produced by toxic chemicals have very long latency periods and we would not expect to see them for some years hence. This is enough of a sampling however to indicate that there are very real victims.

In addition, we know that there are many people who have been exposed to chemicals that in either epidemiology studies or laboratory animal studies have adverse effects ranging from decreased IQs to infertility, to cancer, and respiratory and other problems. We cannot assume that these exposures will not lead to some sort of problems in these human beings.

It will be many years before we know the full extent of injury from toxic chemicals. Those studies have just now begun and it will take some time to document them. Hasty studies done in the near term are not terribly useful for documenting the extent of the problem. I want to emphasize however, that we feel strongly that we know enough to know that there is a problem that needs to be addressed.

This is not a solution in search of a problem as those who created the problem so glibly assert, but a serious problem in search of a thoughtful answer.

Once the premise is accepted that there are victims one must ask if they are being compensated for their injuries? Compensation is important for two reasons, fairness and economic efficiency.

It is a basic tenet of our common law that it is fundamentally unfair that people who are injured are not compensated for their injury. In addition, it is economically inefficient if the costs are borne by others than those who reap the benefit from some social activity. It leads to a situation where the social costs outweigh the social benefits. In addition, when an entity pays the full costs of his activities it should lead to changes in his behavior.

The two most authoritative documents on the issue of victims compensation have concluded that there are very real legal barriers to compensation. These are of course the studies done by the Environmental Law Institute and the study done by the section 301(e) panel under the Superfund law.

They have documented a range of problems including antiquated statute of limitations, proof of causation requirements that fit traditional torts but not toxic torts; standards of liability; joinder defendants and just the general complexity of this type of litigation.

Several proposals have been put forward in reaction to the studies. I will not comment on them specifically but rather address some basic concepts in them.

First of all, we feel strongly that the scope of any legislation should include compensation for all injuries from environmental contamination, not just injuries from hazardous waste facilities.

As appealing as the hazardous waste issue has been over the last year there are also some very real problems with contamination from other sources as the example I have of the children in Dallas, TX indicates.

The Superfund legislation now on the books is not confined to hazardous waste facilities nor should any potential victim compensation legislation.

Second, the section 301(e) panel put forward a proposal for a two-tiered system, an administrative system of compensation and a judicial approach. The environmental community generally supports the concept of a two-tiered system but has some reservations about methods of implementing it.

The administrative step, the first tier, would provide limited recovery of out-of-pocket expenses and lost income up to $2000 a month.

We generally support that concept.

It must however, be accompanied by an easing of the burden of proof that is in traditional tort law. From our point of view, three requirements should be placed and claimants in that burden before the law would provide that the claimant has met his burden of proof.

One is that there is a reasonable likelihood of exposure of sufficient dose and duration to have caused or contributed to the disease.

Second, that there be some link scientifically between the disease and the exposure. Some have proposed this be based on hazardous substance documents. While these documents may be useful to the debate and to any judgment we do not feel they should be relied upon alone since they will undoubtedly be very, very controversial documents and probably will be outdated by the time they are even issued.

Additional evidence in the form of epidemiological studies, statistical studies, animal studies, tissue culture studies should also be admitted. There are problems now admitting this type of evidence.

Third, there should be proof of injury.

This is still, contrary to some assertions, a very large, expensive burden of proof. Proof of exposure alone is a very costly proposition as I know from my days with the Department of Justice when I was trying to put together hazardous waste cases. It entails very expensive, extensive monitoring to find out what the concentrations of pollutants are or were, often after the fact when the evidence has been changed substantially. It may also require very sophisticated computer modeling to forecast where some of that chemical matter has gone.

Proof of the link between exposure and the subtance is also very costly. It will entail very detailed studies, very detailed analysis of very complicated scientific studies. In addition, the medical expenses of proving injury, some of which take sophisticated diagnostic skills, is also very large. These are not common, every-day injuries.

Because of this and because of the fact that the funds that you can get from the administrative approach are very limited, we think that the first tier may not often be used. It is simply too expensive a proposition for too small a benefit.

Therefore, we endorse it but endorse it as a limited remedy and certainly not the exclusive remedy and feel that the second tier, the judicial remedy proposal still remains the most important aspect of victims' compensation.

The section 301(e) study recommended that the second tier be left in the hands of State courts. We feel strongly that a Federal cause of action ought to be created. However, to ensure that the resources of State courts are still used, we recommend that the policy followed in the Federal Employers Liability Act wherein a Federal cause of action may also be brought in State courts be followed.

In addition we feel strongly there should be no preemption of existing State remedies, either legislative or common law.

The Federal cause of action should squarely address the issue of proof of causation and the difficulties in it. The burden of going forward should be premised on the three elements that I outlined in regard to the first tier, that is the plaintiff's burden of proof should be counted as having been met when there is a showing of exposure that produces a likelihood of causing or contributing to the disease; the scientific link between the disease and the exposure; and the injury.

As with tier I this is still a very difficult burden of proof, very expensive. It does not release the plaintiff from having to prove by the traditional test—a preponderance of the evidence that he was injured. Our traditional standard in common law tort cases would still be there. What this does is allow the plaintiffs to introduce relevant evidence that is now often excluded from hearings, and avoid the requirements of traditional theories of tort. One can easily trace a bullet out of a gun into the victim's body. You cannot do that with toxic torts. You cannot trace the molecule out of the smokestack or out of the toxic dump into the victim's body, resulting in disease.

You have to be able to use in these cases some of the more non-traditional types of evidences as epidemiological studies and animal studies.

Liability should be as in Superfund, joint, strict, and several. I know especially the joint and several is controversial, but it is necessary to be sure that plaintiffs have workable cases and that they don't have to identify every last possible defendant before they sue. In addition we part company with many of the proposals that have been put forward that would limit liability to diseases that are caused by exposure that occurs after the date of enactment of any legislation.

We do this for two reasons, first of all we think this may be a fundamentally unworkable provision. How do you distinguish with diseases that have long latency periods whether they arise from exposure before or after enactment? I suggest that that is rather an impossible provision and would lead to protracted litigation.

Second, the sums that have been suggested for victim compensation, particularly in the administrative stage, the fund is rather small. The bulk of the problem right now and for the near future is going to be from exposure that occurred before the date of enactment of any legislation. Unless there is a significant increase in the amount of money in these funds you are going to create a problem by saying that the fund cannot be subrogated to the rights of plaintiffs if the state of exposure predates the legislation.

With that general overview I will again thank you for the opportunity. I would be happy to answer any questions.

[The statement of Ms. Hall follows:]

TESTIMONY OF KHRISTINE L. HALL

Mr. Chairman, members of the Subcommittee, my name is Khristine L. Hall. I am an attorney with the Toxic Chemicals Program of the Environmental Defense Fund. Thank you for inviting me to testify on the issue of compensating victims of exposure to toxic substances.

The Environmental Defense Fund (EDF) is a national not-for-profit environmental organization with a nationwide membership of approximately 47,000. The goal of EDF's Toxic Chemicals Program is to minimize or prevent exposure by people and the environment to toxic chemicals. Over the past decade, EDF has worked to insure proper implementation of a number of regulatory programs concerning toxic chemicals: the Food, Drug and Cosmetic Act, the Clean Water Act, the Clean Air Act, the hazardous waste provisions of the Resource Conservation and Recovery Act, and others. Most recently we have been actively involved in implementation of the Comprehensive Environmental Response, Compensation and Liability Act (Superfund). Our work on these programs, especially of Superfund, has aroused our concern about the ability of people who are injured by exposure from toxic substances to be compensated for those injuries.

Discussions of the important issue of providing a better mechanism that now exists to insure compensation to those people who have been injured by toxic chemicals has recently resumed after being curtailed by the passage of Superfund in 1980. EDF was among those organizations that worked for inclusion of a victim compensation provision in Superfund. While we understand the political necessity of dropping such provisions from the final bill to ensure passage, we remain convinced of the necessity of such a provision.

Over the past several months, I have been meeting periodically with representatives of environmental organizations, citizen groups, and other public interest organizations to discuss victim compensation. While I am not prepared today to lay out a detailed formal position on behalf of those organizations. I can state unequivocally that the environmental community strongly supports enactment of victim compensation legislation in this Congress. To allow the inconsistency of Superfund—which provides for compensation for natural resources damaged by toxic chemicals, but not people who are injured by toxic chemicals—to stand for much longer is not good public policy.

Our support for legislation is premised on (1) the fact that there are people who have been injured by toxic chemicals and (2) the current legal system presents a number of difficult and sometimes insurmountable barriers to recovering compensation for those injuries.

PEOPLE ARE BEING INJURED BY TOXIC CHEMICALS

Out of 112 blood samples taken by the Centers for Disease Control from people living in dioxin-contaminated neighborhoods in Missouri, all 112 samples showed biomedical evidence of liver dysfunction.

The rate of heart defects in infants born to mothers in San Jose, California, who consumed water contaminated with trichloroethane (TCA) is significantly higher than the rate in the general population.

Many children living near a lead smelter in Deere Park, Texas have severely elevated blood lead levels—well above levels the Public Health Service defines as lead poisoning.

Scientists have found that children in Michigan with a high body burden of polybrominated biphenyls (PBBs) in their fatty issue have decreased intellectual capacity, as measured by school performance.

A significant number of the rural population of Hardman County, Tennessee that drank chemically-contaminated drinking water have symptoms including liver damage, enlarged liver, or optic atrophy.

These are but a few examples of where toxic chemicals have caused injury to human beings. They are examples that have come to my attention in recent months. This is not a complete list—nor could it be, since we have only recently begun to study and document the effect of toxic chemicals on people and since some diseases caused by toxic chemicals have long latency periods.

It is enough of a sampling, however, to indicate that there are, in fact, real victims of exposure to toxic chemicals. In addition, we know that some people are exposed, through the air they breathe, the water they drink or the food they eat, to a broad range of substances that have been shown in animal tests and epidemiology studies to cause cancer, birth defects, infertility, lowered IQs, respiratory problems, and other serious illnesses. Dose levels for some of these exposures are relatively high. We cannot assume that there have not been and will not be human injuries from such exposure.

It may be many years before we can reasonably expect to have scientifically documented the full magnitude of injuries caused by toxic chemicals. Hasty studies undertaken with an eye toward pending legislation will not produce such documentation. I want to emphasize, however, that the environmental community believes we have enough evidence in hand to indicate that people are being injured by toxic chemicals. This is not a solution in search of a problem as those created the problem so glibly assert, but a serious problem in search of a problem as those who created the problem so glibly assert, but a serious problem in search of a thoughtful solution.

LEGAL BARRIERS PREVENT RECOVERY OF COMPENSATION

Once the premise is accepted that people have been or will be injured from the toxic chemicals now found in our environment, two questions should be asked: (1) What can society do to minimize or prevent exposure to these toxicants and (2) Are the victims being compensated for their injuries?

The answer to the first question lies largely in more effective regulation of the way toxic chemicals find their way into the environment. Considerable thought has been addressed to this issue over the past decade. Although improvements are in order for many of our efforts (e.g., toxic water pollution amendments pending before this Committee, the pending reauthorization of the Resource Conservation and Recovery Act, and new amendments to the Clean Air Act and the Toxic Substances Control Act), action has at least been initiated.

Unfortunately, the second question—concerning compensation—has not yet been adequately addressed. The starting point for any inquiry is the basic question of why we should be concerned about making sure that victims of toxic chemicals are compensated. It is a basic goal of our tort system that each victim be compensated by the entity inflicting harm on him or her. This goal rests primarily on the principles of fairness and economic efficiency. It is fundamentally unfair if a victim is not compensated for injuries received as a result of activities carried on by and benefiting another. Furthermore, injuries resulting from an activity are part of the social cost of that activity. If those costs are borne by someone other than the entity reaping the benefit of the activity, and more important, making the decision as to the amount of the activity, then an economic inefficiency occurs. That inefficiency could result in a level of activity at which the social benefit from the activity does not outweigh its social costs. A variant of this theory is that if a polluting entity is made to pay the full cost of the damage it causes, such economic costs may change the manner in which business is conducted.

The issue of whether a victim has been adequately compensated is thus important—both to the victim and to society. Delay in solving problems in compensation cannot, therefore, wait the many years it will take to thoroughly document the extent of the problem.

The two most authoritative documents to address this important issue of whether current remedies are adequate—the Environmental Law Institute's report entitled "Statutory Reform of 'Toxic Torts' Relieving Legal. Scientific, and Economic Durdens on the Chemical Victim" and the Superfund Section 301(e) report. Injuries and Damages from Hazardous Wastes—Analysis and Improvement of Legal Remedies,"—both conclude that our present system or tort law is inadequate to insure compensation to victims of toxic chemicals. To quote from the Section 301(e) Study Group:

"The Study Group concludes (1) that there are causes of action on which to base a claim for damages for such injuries or damage; (2) that there are many substantive and procedural barriers to recovery; and (3) that existing courses of action and existing barriers to recovery will allow some recoveries in a number of highly selected cases. Available, remedies are inadequate in view of the substantial number of claims that may arise, and the factual and legal complexities that will be involved in their litigation."

It is fair to say that our present tort system is behind times in dealing with modern society and the injuries produced in modern society. Od rules which worked well when industrialization was just beginning have been slow to adapt to the complexities of our technological age. Problems such as antiquated statutes of limitations, proof of causation, standard of liability, and joinder of defendants, as well as the general complexity of toxic tort litigation, have blocked recovery or made it so difficult as to discourage seeking it. Although progress has been made in some states on some issues, major problems remain, as a general matter, that deserve attention and solutions.

WHAT ARE THE SOLUTIONS

Descriptions of the problem is the easy part of this controversy. Finding a meaningful, fair solution is not so easy. Several specific legislative proposals, incorporating different approaches and concepts have already been put forward in both the House and Senate side. Rather than commenting specifically on these bills, I would like to make a few suggestions and to address concepts incorporated in the bills generally and in the ELI and 301(e) studies.

A. Scope of coverage

Victims compensation legislation should cover injury from all environmental exposures—not just from hazardous waste. Although the hazardous waste problem is dramatic and exposure to it significant, exposure to toxic chemicals through other environmental media is also important, as illustrated by the blood lead levels in children close to the lead smelter in Texas, cited above. It makes little sense for a person whose injury arises from exposure to lead from a smelter to have to follow different, more stringent rules for recovery than the person whose injury arose from a hazardous waste site. We note that Superfund coverage is not confined to hazardous waste sites and believe that victims compensation legislation likewise should be broad enough to cover all environmental exposure.

B. Two-tiered system

The section 301(e) panel proposed a two-tiered recovery system, with the first tier being an administrative mechanism and the second tier a judicial approach. This approach has been adopted in some of the bills that have been introduced. We endorse the general concept of the two-tiered system, with reservations about details of its implementation.

1. Tier I—Administrative mechanism

As laid out in the Section 301(e) study, Tier I would establish an administrative mechanism for taking evidence from potential victims and making awards from a Fund, financed primarily by a tax on industry. We would propose that EPA administer the compensation system, but that the board or panel making findings also have representation from Health and Human Services.

We propose that recovery from Tier I be limited to lost income up to $2000 a month and reasonable out-of-pocket expenses (i.e., medical expenses, cost of relocation). This differs from the recommendation of the Section 301(e) panel only in allowing other reasonable out-of-pocket expenses (such as the expense of a forced relocation) to be recompensed in addition to medical expenses.

To make this process work, the burden of proof now generally required of plaintiffs would have to be eased. We recommend that legislation state that a plantiff has met his burden of proof, subject to rebuttal, by showing the following: (a) reasonable likehihood of exposure of sufficient duration and dose to produce injury; (b) scientific link between injury and exposure to chemical; and (c) injury. This is not unlike the rebutable presumption recommendation of the Section 301(e) panel for Tier I.

In establishing the second element, the scientific link between injury and exposure, plaintiffs may rely on Toxic Substances Documents, if available. As recommended by the Section 301(e) panel, these documents would provide evidentiary data showing that specific hazardous substances or wastes cause specific diseases or illnesses. Because preparation of these documents is likely to be protracted and the subject of intense debate, they will undoubtedly be produced only late in the process. In addition, because of the rapid rate that scientific discoveries are now being made about toxic chemicals and their effects, these documents are also likely to be outdated when finally produced or shortly thereafter. We therefore recommend that plaintiffs be allowed to rely on other scientific evidence available tending to prove cause-and-effect or correclation between exposure to a chemical and disease. This would include epidemiological studies, animal studies, tissue culture studies, and micro-organism studies.

This approach leaves in place a very considerable burden of proof on plaintiffs. Proof of a reasonable likelihood of exposure of sufficient dose and duration to cause injury is very difficult. In many instances, it will require extensive and expensive sampling and sophisticated modeling and analysis to prove the fact of exposure and the concentrations of the pollutants—often after-the-fact when circumstances have changed or evidence altered.

Establishing the link between exposure to the chemical and disease is also an expensive proposition, given that we doubt the widespread avialability or usefulness as the ultimate resource of the Toxic Substances Document. Expensive research and analysis will also be required for this step.

Finally, establishing the medical fact of injury with certainty of diagnosis may also be expensive. As everyone is aware, any visit to the doctor is expensive. Medical attention to unusual conditions or diseases caused by toxic chemcials requires special expertise, which is even more expensive.

In short, although this proposed approach eliminates some barriers in the current system and allows the introduction of more evidence than often allowed by courts now, it still presents a very high hurdle to recovery. Hiring the necessary technical people, analysts, and expert witnesses is still very expensive—in many cases more expensive than the small amount of money proposals would allow to be recovered under Tier I.

This is an important point. What it means is the Tier I may not be used with success very often. It is for this reason that we view Tier I as a very limited remedy of limited utility. In fact, the Tier I does not even begin to address the bigger, more complicated issues associated with injury from exposure to toxic chemicals, such as pain and suffering, compensation for loss of intelligence, and compensation for loss of fertility. We support establishing Tier I as a way of dealing with very small injuries and as a means of gaining experience in this area with administrative compensation mechanisms. Given its limited utility and scope, however, it is clearly not a substitute for Tier II. We therefore vigorously oppose any efforts to limit compensation to Tier I or to force a binding choice between Tier I and II.

2. Tier II

The second tier is resort to the judicial system. The Section 301(e) panel essentially left Tier II up to the state courts, while making recommendations on ways in which state legal requirements should be changed to enhance recovery possibilities. This approach ducks the issue and is unacceptable, given the continued importance that judicial remedies will play in any viable compensation system. While some states have already adopted and other states will adopt, either through court decision or legislation, some of the reforms recommended by the Study Group, reliance on the state court system will result in a patchwork quilt of remedies, when viewed from the national perspective. Just as it has been necessary to establish minimum federal standards and guidelines as a floor for pollution control, so too is it necessary to establish minimum federal rules governing compensation systems.

It is for this reason that we commended establishment of a Federal cause of action, incorporation reforms recommended by the Section 301(e) Study Group. To insure that the resources of our state court system continue to be used, we suggest that this federal cause of action may be brought either in the state courts or in the federal courts. There is precedent for this approach in the Federal Employers Liability Act (FELA—45 U.S.C. § 56). Plaintiff should also be allowed to use state courts and causes of action.

There should be no limits on the amount or type of recovery. In addition, legislation should make clear that the plaintiff's burden of going forward has been met by showing the same three elements of the rebuttable presumption in Tier I: (a) reasonable likelihood of exposure of sufficient dose and duration to cause injury: (b) link between exposure and injury and (c) injury. This approach does not relieve plaintiff from proving his case by a "preponderance of evidence" as is now the usual standard in civil liability cases. Rather, it allows plaintiff to introduce more types of evidence (such as epidemiology studies, animal studies, etc.) without challenges to relevency and relieves plaintiff of the burden of tracing a molecule of the pollutant from the source into the body to produce the injury. This burden, which traditional tort law may require, is and will remain impossible to meet. This approach allows plaintiff to take evidence relevent to modern injuries to the jury. Defendant, of course, still may introduce countervailing evidence.

As discussed above, this is still a very considerable, expensive burden of proof. Defining the burden of going forward in this manner does not mean that plaintiff will always prevail; it does mean giving plaintiff the opportunity to present his case in the only way relevant to modern injuries to the jury.

C. Liability issues

In accordance with the recommendations of the Section 301(e) Study Group, liability for incident that causes or contributes to the injury complained of should be strict, joint and several. This standard should apply both to direct judicial actions by injured plaintiffs and to claims by the Fund subrogated to plaintiffs' claim. Strict liability is necessary so that plaintiff does not have to prove fault—an impossible burden of proof in most of these cases.

Joint and several liability is necessary because of the difficulty of locating all defendants who may have caused or contributed to the injury. Delays in the onset of disease as well as, for instance, the fact that many companies may have used the dump from which a toxic substance leaked mean that, in the words of the Section 301(e) Study Group:

"It is impossible here, as in other instances of environmental pollution to attribute and allocate responsibilities and liabilities with specificity. Substantive and procedural rules that require such specific allocation will defeat the plaintiff's claim."

For this reason, the Section 301(e) Study Group recommended the use of the common law concept of joint and several liability. To soften the potentially harsh effects of joint and several liability, the common law excepted those whose contribution to the injury was de minimus. This should be incorporated, as well as a specific provision that liable parties may seek contribution from other parties.

The Fund should be subrogated to all plaintiff's claims, whether based on present or past action. The Section 301(e) Study Group had recommended subrogation only for claims arising out of exposure after the date of enactment. This restriction is unworkable—for long latency diseases there may be no way of determining whether exposure occurred before or after the date enactment. In addition, for some time to come, most claims will arise from exposure occurring before the date of exposure, thus placing a severe drain on the Fund. Since the allocations to the Fund provided for in various bills are very modest, we doubt that this is good policy.

CONCLUSION

I want to thank you for the time you are taking to explore this important question. The issues are complicated and deserve in depth consideration and thoughtful discussion. They are resolvable, however. We urge that resolution occur in this Congress. I would be happy to answer questions.

Mr. LEVITAS. Thank you very much, Ms. Hall.

Perhaps you can tell me just so we would have a matter of record, have you handled any litigation personally involving hazardous waste sites or toxic torts?

Ms. HALL. I have not handled toxic tort litigation. When I was at the Department of Justice I helped put together the cases against *Hooker Chemical Co.* concerning *Love Canal, Hyde Park,* and a couple other hazardous waste cases. So I know the difficulty just from that perspective of trying to put together a case that is going to argue that there has in fact been some effect from the hazardous waste.

Mr. LEVITAS. In your statement you mention that you believe victim compenation legislation should cover injury from all environmental exposures; however we have received testimony and read other materials from experts who believe there is insufficient scientific data to conclude that injury results from exposure to hazardous wastes. How would you reconcile these two widely divergent positions?

Ms. HALL. As I tried to outline in my statement, I think it will be quite some time before we do know the full magnitude of injuries from toxic chemicals generally. That process of studying the effect of toxic chemicals on human beings has just begun. In fact the mechanism that the Public Health Service is now using for documenting exposure and resultant injuries is something that began as a result of an EDF lawsuit about 3 months ago.

It will be many years before we have conclusive results from that study.

At the same time I think one can point to enough instances across the country—I have tried to outline a few of them in my testimony—where there is scientifically provable, clinically provable, instances of injury from hazardous chemicals.

As I stated, this is not a full catalog—it is probably impossible to compile a full catalog—but it is indicative of the fact that there is a problem. We also know that many people are now being exposed and have been exposed to toxic chemicals that we know from epidemiological studies and from animal studies lead to a range of results of injuries, and those two combined leads us to believe that there is a large problem that demands a solution.

Mr. LEVITAS. You made an interesting comment about the question of admissibility of evidence as one of the major problems. I used to teach evidence in law school and have been very interested in the artificial restrictions on denying triers of fact full information as a result of these rules of evidence.

In this particular situation is there a special reason why there should be a change in the rules of admissibility as opposed to other types of tort litigation?

Ms. HALL. Well, the type of evidence we are talking about, statistical evidence primarily, arises preeminently in this field of toxic torts. I am not aware of other areas where it might also arise. Epidemiology studies are, however, relevant to toxic torts whether they occur in the workplace or from environmental exposure. There is also a long line of cases on relevancy and admissibility on epidemiology studies with respect to HEW's Swine Flu program several years ago.

So there are related areas where it is also an issue.

Many courts have been very reluctant to admit this type of evidence or if they admit it to give very little weight.

Mr. LEVITAS. Can't you get that evidence in through an expert witness using it as a basis for formation of his opinion?

Ms. HALL. From the cases I am aware of, specifically on epidemiology studies, in some cases that is possible. In other cases courts have concluded that since an epidemiology study does not address specifically the issue of whether a particular plaintiff contracted the disease but goes to a general population, it is not relevant. You can also get it in in some instances, in some cases, as being relevant circumstantial evidence.

Other courts have excluded it because they feel it is confusing and too technical for a jury to understand.

There have been a range of reasons. The courts are beginning to open their minds to this but it has been a problem. I think you have even more of a problem when you move from epidemiology studies which use real human beings to animal studies and you have an extra leap to translate the animal data to human beings.

Mr. LEVITAS. I have just a couple other questions, but one of them is on the subject that you raised about injuries occurring or manifesting themselves before or after enactment.

A more serious ongoing question would be on the question of statute of limitations. We heard yesterday that there is pretty much consensus that there should be a 3-year statute of limitations based on the discovery of the injury.

Ms. HALL. Yes.

Mr. LEVITAS. Now, I was surprised to hear everybody seemed to agree on that when there seems to be a whole can of worms there since most of the types of illnesses or injuries that are connected with toxic chemicals are the same type of illnesses or diseases that people might receive from other sources, liver problems, kidney dysfunction, skin rashes, respiratory problems, all of these things you can get without ever being exposed or certainly not as a causal factor being environmental reasons, how would one know when you got—given the long latency period as well—how would one know or be in a position to make a judgment that when they develop a kidney dysfunction or a respiratory illness that that is a result of exposure *x* number of years ago to toxic chemicals?

Ms. HALL. First of all addressing the statute of limitations problem. I didn't include it in my testimony because I, too, perceive there is general consensus that it should be changed.

I don't think the statute of limitations issue is the way of getting to the problem you have just raised.

One of the ways of addressing that issue is by reliance on epidemiology. for instance, the people at Hardeman County, Tennessee and the mothers in San Jose, CA—by surveying through scientific methods a community one can determine whether in fact the incidence of a disease or injury is elevated above naturally occurring levels of disease.

If there is a statistically significant elevation that suggests that the cause is the environmental factor and not just some natural background.

Mr. **Levitas**. That deals with the question of proof, once someone made the judgement I got sick because of the environmental exposure.

If I became ill next week with a somewhat common ailment, how would I be able to make a judgment that that was caused as a result of my living near a hazardous wastesite when I was in the Air Force in Maine back in the 1950's?

Ms. **Hall**. Common ailments are the biggest problem in this, skin rashes, respiratory diseases, minor infections, they are the biggest problem because those are the things that occur with more frequency in the background.

Other diseases such as heart defects, liver dysfunction, certain types of cancer, are not so common and one can through these statistical methods distinguish populations.

It is somewhat ironic that the section 301(e) panel thought that first and foremost—from what I read of their deliberations—they were providing remedies for the small problems when they are probably scientifically the most difficult to distinguish and probably be the ones that will take many years to be able to develop a basis for.

My understanding is that—and being an attorney I am hesitant to comment on it—is that there is a growing body of knowledge on immunology where you can now do tests on immunological deficiencies to determine whether or not because of deficiencies in your immune system that you might not be more subject to infections, respiratory problems, that sort of thing, and that can be done biomedically and scientifically to determine what shape your immune system is in.

Mr. **Levitas**. Well, I won't belabor this point because we want to address a broad range of issues, but I can see now if I were a defense attorney representing a defendant in a toxic tort situation under a 3-year statute of limitations of the sort we are talking about, that in the course of discovery I would try to find out what symptoms or illnesses this individual manifested over the last 5 or 6 years and if I could spot one 5 years ago or 3 years and 1 day ago, that could also be related to that exposure to the same chemical, I would suggest that the injury had manifested itself 3 years, 1 day ago and even though you are suing about another injury now, also possibly related, that you have been caught by the statute.

As I was listening to that testimony yesterday that seemed to be a real problem to me.

Let me go on to the final point. I notice as I was listening to the lawyers testimony yesterday I began to feel—maybe I am in the wrong line of business now.

Ms. **Hall**. I am a lawyer, too.

Mr. **Levitas**. We have this whole deal of contingent fees, if you find the right case you have a pretty good horse to ride and I know, I know Mr. Molinari and Dr. Rowland and I were talking about it, we are creating a situation maybe in which lawyers are going to come out pretty well on this thing and how much of the resources we devote will actually go to the victims and how much will go to the attorneys is something we have to look at as we approach a Tier I system or a Tier II system.

But you recommend not only a special legislation matter and Federal preemption——

Ms. **Hall**. No, not Federal preemption. I want a Federal cause of action.

Mr. **Levitas**. You want a Federal cause of action in Federal courts, all right.

Now, the witnesses yesterday all seemed to believe that the existing common law tort system was an adequate means of addressing the compensation issue in the judicial context; once you got above a Tier I situation.

Also, I would have great concern—just as a matter of policy—of creating any new cause of action in a Federal court that could be handled appropriately in a State court that was not inherently a Federal or interstate commerce type of matter for a lot of reasons which I am sure you have heard as other lawyers have heard, all the policy reasons.

Why do you think you need a Federal cause of action. What is wrong with the tort system in the State courts? They seem to be at least as competent as Federal courts in many instances.

Ms. **Hall**. The basic reason for wanting a Federal cause of action—and I also added that we would have no problem with seeing a Federal cause of action that could be brought in State courts as the Federal Employers Liability Act now provides—is to establish some baseline rules which you cannot do for State courts, to address some of the legal barriers that have been documented in various studies such as statute of limitations. A number of States still have very antiquated statutes of limitations and to go State by State to try to change that could take a number of years.

A number of States still do not recognize strict liability as the appropriate standard of liability in these cases. Having to go under a theory of negligence places a very, very high burden on plaintiffs to try to prove their case. They have to prove some sort of fault. In the big cases, for instance the ongoing litigation on agent orange I think it is going to be fairly easy to show some sort of negligence. But in the run of the mill cases a showing of fault is very difficult.

Some States recognize joint and several liability, other States, for instance, Missouri where I just filed a brief under Superfund legislation, do not. Missouri is out of step with most of the rest of the States, but there are still several States that do not recognize what I regard as a minimum legal requirement for bringing these cases.

So our main concern is making sure that there are some minimum changes in rules that now exist in some places. Just as it has been necessary to put a minimum Federal floor on pollution control standards we feel there should be a minimum Federal floor on some of these rules that govern compensation.

Mr. **Levitas**. Thank you, Ms. Hall.

Mr. Molinari.

Mr. **Molinari**. Thank you, Mr. Chairman.

Ms. Hall, I, too, have problems with the question of statutes of limitation.

I think in this room we probably have a lot of people who have a great deal of familiarity with the kinds of symptoms that people exhibit when they have been exposed to chemicals such as we are discussing.

But I guess most of us relate to personal experiences to understand the real world out there. Back in my community there is a dump where very large quantities of different chemicals were deposited systematically over a period of, a year-and-a-half or 2 years.

The people in the neighborhood were complaining to their doctors of a variety of symptoms and really didn't know nor did the doctors, about the source of the problems. In fact there were different diagnoses until 2 years later, during the course of a Federal trial in Pennsylvania, that there was this dumping.

As soon as that became public, the people started running back to their doctors and the doctors had a better handle on the possible source of their problems. It may have been that they might still have been able to start a lawsuit under the statute of limitations in New York, but I am not sure.

Why do we suggest having the statute of limitations toll from the time when the people have evidence of injury rather than discovery of the source?

Ms. HALL. It can be formulated either way and legislative——

Mr. MOLINARI. I understand that but I thought it was your recommendation or the recommendation——

Ms. HALL. No, I have made no explicit recommendation in my testimony on exact wording. I believe it should be formulated from the—it should run 3 years from the date of exposure or from the date of knowledge of what caused it.

Mr. MOLINARI. Constructive or otherwise?

Ms. HALL. That is right.

Mr. MOLINARI. On that score I would like to say that I would like to see the attorneys making more money—I don't mean a percentage more—but more total earnings in toxic tort litigation because I think the net result of that would be that more people out there who are being injured would be getting compensation; I think too many of them are not under the present system. That is why we are talking here today.

Ms. HALL. I agree with that obviously.

Mr. MOLINARI. I have just a couple other questions I want to ask you.

I was surprised at the testimony of Mr. Baron yesterday—were you in the room?

Ms. HALL. I was not unfortunately, I was busy writing this testimony for today.

Mr. MOLINARI. He kind of shocked us, I guess, by suggesting that the state of the art today is such that lawyers, particularly like those in his firm who specialize are able to develop a case. There has been great disagreement as to what resources it would take to properly develop such a case, but he believes that existing law is adequate, despite the fact that I think he mentioned there is only one other firm that he knew of that is doing this on a regular basis.

Mr. Baron was also a member of the 301(e) study group, so he has some rather impressive credentials. I must say that it made me stop and consider for a moment: if this is a man that has had actual experience—and he probably has had more than just about anybody else that we know of—and after that experience he has suggested leaving the system alone, perhaps it can be handled as it is, in that people that are being harmed have adequate remedies at law today.

Would you comment on that?

Ms. Hall. I think you have put your finger on the difference between Mr. Baron and other points of view of lawyers. He has at his disposal extraordinary resources to put these cases together and he is used to dealing with them. But he is one of a kind or one of a very small handful.

We deal in our work on Superfund with communities across the country, small communities across the country who don't have access to the Mr. Barons and who have access only to the local lawyer down the street. I am not suggesting that a lot of the cases will be brought by the local lawyer down the street but even in cases, for instance, of working with a fairly good-sized firm the lawyers are struggling with these cases. The ordinary case in a lot of States is going to run into legal barriers that have been well-documented by studies including the one Mr. Baron participated in.

I did some consulting with a firm out in the San Francisco area, a large plaintiffs firm that didn't know where to start and is really having some problems with putting together a classic toxic tort case. And it seems to me to address the full breadth of the problem and not the really big and sexy cases, you are going to have to have some easing of some of the barriers that are now contained in the law.

Mr. Molinari. My own impression is that the average lawyer who has a prospective client walk in and relate that they believe they have a physical problem due to a dump that is two or three or four blocks away, may talk to them for a brief period of time, to look at the case as a loser and suggest they go to the bar association. I don't know that the average lawyer is, in his own personal knowledge, aware of firms specializing in toxic tort litigation.

Ms. Hall. It is a big problem. I get several phone calls a month from lawyers wanting to know where they go and what they do.

Mr. Molinari. What is your answer to them?

Ms. Hall. I fill them in as best as I can and point them in the direction of people that I know who have handled some cases and generally wring my hands over it.

Mr. Molinari. Do you have a catalog of attorneys that handle these matters?

Ms. Hall. I don't make formal referrals, no.

Mr. Molinari. You don't?

Ms. Hall. We do not. That is a service that is needed, however.

Mr. Molinari. Is it something you are considering or is it against policy of EDF to do so?

Ms. Hall. It is controversial within the organization now.

Mr. Molinari. Sorry?

Ms. Hall. It is a controversial issue within my organization now.

Mr. Molinari. I see. I just have one last question, Ms. Hall.

You make reference to the Missouri problem and the blood samples showing liver dysfunction. Were you able to determine from your own inquiry whether that liver dysfunction was reversible?

Ms. Hall. You need to ask the scientists that, not me. But my understanding is that it shows that the liver has fundamentally been damaged and that is all I know.

Mr. **Molinari**. I have no further questions, Mr. Chairman, thank you.

Mr. **Levitas**. Thank you very much.

Dr. Rowland.

Mr. **Rowland**. Thank you, Mr. Chairman.

Ms. Hall, what do you think is the most important thing that Congress needs to do now with reference to hazardous waste dumps and toxic chemicals that people are exposed to and things of this nature. What is the most important thing Congress needs to do in your opinion?

Ms. **Hall**. Well, I really have a two-pronged answer to that, sorry. One is to tighten up regulations. You have a variety of means to do that: the Clean Water Act pending before this committee, specifically the provision on toxic water pollutants, the RCRA reauthorization that will hit the floor sometime later this week, amendments to a variety of issues to make sure that we tighten our control and regulation of toxic chemicals to prevent future injuries.

Second, providing a better system to ensure that people who are injured are compensated.

Mr. **Rowland**. I have had concern—and I expressed this yesterday—that allowing suits to be filed in this area when we are not even sure exactly what detrimental effects of these chemicals may be, the fact that there is a new area opening up in the law and only two firms are involved, that is, in toxic chemicals, that we may be opening an area that will be good for lawyers who are involved in tort situations and might really cause ourselves a lot of difficulty and I see you are saying there should be no limits on the amount or type of recovery.

Ms. **Hall**. In judicial proceedings.

Mr. **Rowland**. Maybe I misinterpreted that since I am not an attorney, you are not talking about the amount that a person who may be injured could recover?

Ms. **Hall**. No, in Tier II, which is the court cases area, there should be no limits on recovery.

I feel fundamentally that putting some sort of statutory limitation on recovery will result in the problems we have, for instance, in the nuclear area where essentially government is subsidizing, underwriting, the costs of doing business, and I don't feel that that mistake should carry over to this area.

Mr. **Rowland**. Then am I to interpret this statement as meaning then that the amount of money that a person could recover is unlimited?

Ms. **Hall**. Commensurate with his injury and whatever he is able to prove.

Mr. **Rowland**. You don't have any concern that we might be opening up an area that could cost a lot of money to industry for example, and the costs being passed along and we would be providing a better livelihood for attorneys in an expanding area?

Ms. **Hall**. I have two comments.

One is I feel right now that industry is not paying the full costs of its activities because they are causing a lot of injuries that are not being compensated. As I discussed briefly in my testimony I think that is economically inefficient and that they should be paying the full cost of their activities.

Second, yes, as a lawyer, not as a tort lawyer but as a lawyer, I am sometimes alarmed by the amounts of recoveries that I see but the problem is not limited to toxic tort cases. The problem is a general problem now with tort cases. I am somewhat relieved to read that on review a lot of these very, very high awards are being overturned. I don't think there should be an artificial ceiling placed on recovery because that artificial ceiling as we have seen in other areas is bad policy.

I think the problem has to be addressed broadly in the tort area and not specifically with regard to environmental problems.

Mr. **Rowland**. You think then that having industry to pay the full amount or a great deal is a way to get industry to clean up their act so to speak?

Ms. **Hall**. I think it is one of the ways of getting industry to clean up their act, that is correct. I think it is one of the economic incentives that can complement Federal and state regulatory programs.

Mr. **Rowland**. You are saying that to do this would do two things, compensate the victim and get industry to clean up their act?

Ms. **Hall**. I am saying that it may have the second effect. I think the primary purpose is compensation of the victim but there are studies that seem to indicate that it may also have a salutory effect on the social behavior of the entities that caused the toxic chemicals to enter the environment in the first place.

Mr. **Rowland**. You feel that the industry costs for this should be passed along as a cost of doing business to the citizenry as a whole?

Ms. **Hall**. That is correct.

Mr. **Rowland**. Thank you, Mr. Chairman.

Mr. **Levitas**. Thank you.

Mr. Molinari.

Mr. **Molinari**. I have a further question that I would like to ask if you would yield, Mr. Chairman.

We heard from some victims last week, specifically an individual who allegedly sustained a very severe injury from exposure to toxic chemicals. The amount of expenses that he has incurred so far run over $100 thousand—I don't recall the exact amount.

The impression I got was that he had no money, so he is probably receiving public assistance in order to survive. I am not sure of that; that is speculation on my part.

Assuming that is the case, when we look at a so-called victim of that circumstance and we try to estimate who should pick up the tab, we are faced with these considerations, among others: Should it be the taxpayers? which would naturally be the case if he was on public assistance; or should it be borne by the industry which has created the chemicals that caused the problem, or any other intermediaries who contributed to causation?

Just an observation, really, rather than a question. I think it answers itself; but it is an interesting philosophical question and one which Dr. Rowland raised very well.

Thank you.

Mr. **Levitas**. Do you want to comment on that?

Ms. **Hall**. I agree that the costs should be borne by the people who caused the problem and not by the public at large.

Mr. **Levitas**. Yesterday one of the witnesses on that excellent panel of attorneys indicated that he left a lucrative practice of law in the field of aviation and structural scaffolding to move into toxic tort areas as an almost social conscience decision. I won't express any judgment on that. But based on what you know at the bar and what is occurring, take the case that Mr. Molinari just talked about, a person has a couple hundred thousand dollars' worth of medical expenses or other expenses. That translates into some rather substantial recovery plus pain and suffering and loss of future income and things like that.

Ms. **Hall**. Yes.

Mr. **Levitas**. Operating on contingent fees if nothing else—isn't this a pretty lucrative area of the law?

Ms. **Hall**. Being a public interest lawyer, I cannot say anything about that.

Mr. **Levitas**. I thought you would be more objective, that is why I asked you the question.

Ms. **Hall**. I think for the people who rise to the top of it and there will obviously be people who rise to the top of this area of specialization, it will be lucrative. For the ordinary lawyers who represent the ordinary citizens in the ordinary cases I don't think it will be necessarily all that lucrative, no.

Mr. **Levitas**. Well, I thank you for your testimony. I was particularly interested in your observations on the evidentiary question which I think places a new light or avenue that we certainly ought to be exploring and because of your expertise in this area you have helped us greatly.

Thank you so much.

Ms. **Hall**. Thank you.

Mr. **Levitas**. The next witnesses I will ask to come together as a panel, are Mr. Leslie Cheek III, vice president-Federal affairs for Crum & Forster Insurance Cos.; and Ms. Sheila Birnbaum, of counsel, Skadden, Arps, Slate, Meagher & Flom.

May I ask that you raise your right hand.

[Witnesses sworn.]

Mr. **Levitas**. Thank you very much.

TESTIMONY OF LESLIE CHEEK III, VICE PRESIDENT-FEDERAL AFFAIRS, CRUM & FORSTER INSURANCE COS.; AND SHEILA L. BIRNBAUM, OF COUNSEL, SKADDEN, ARPS, SLATE, MEAGHER & FLOM, REPRESENTING AMERICAN INSURANCE ASSOCIATION SOCIATION

Mr. **Levitas**. We might start with you, Mr. Cheek, and we will hear from Ms. Birnbaum and then the subcommittee can put its questions to both of you.

Mr. **Cheek**. Thank you, Mr. Chairman.

If I may, I would like to ask that my prepared statement be put in the record.

Mr. **Levitas**. Yes. Without objection the prepared statements of all of the witnesses today will be made part of the record and my request again, if you would try to limit your opening remarks to approximately 10 minutes so we can get into the questions.

As I said earlier, the role of the insurance field in this area as well as many other areas is very significant in terms of how we determine what social policy to pursue through legislation. So I am most interested in your comments.

Mr. **Cheek**. Thank you, Mr. Chairman.

The Crum & Forster Insurance Cos. are the Nation's 14th ranked group of property-casualty, insurers with 1982 premiums of approximately $1.7 billion. Our companies are among the largest writers of the principal nonfault system in the United States, workers' compensation, and also of coverage for businesses subject to tort and environmental cleanup liability.

We also write a substantial amount of insurance for vehicle owners in States that have hybrid fault and nonfault automobile insurance compensation systems. We think that the lessons we have learned from working with these different kinds of systems might be useful to the subcommittee in evaluating which way to go on this victim compensation issue.

Our principal interests in any compensation or liability system are the predictability and affordability of its costs. Without a reasonable certainty as to how many persons will make claims against the system and how much on the average each claim will cost, we cannot determine the appropriate premium to charge our customers. And if our customers can't afford what we are trying to sell them, we are out of business.

The Congress, too, we think, should be sensitive to both the predictability and the affordability of the costs of any system it creates to deal with what so far, in our view, is a very poorly defined and perhaps even nonexistent problem.

The Congress' last venture into a specialized compensation mechanism, the Black Lung Benefits Act, as you well know, produced a system that was initially estimated to cost $40 million a year and is now running along at a cost of about $2 billion a year.

The premise underlying the study group's proposals for new mechanisms to deal with hazardous substance-related claims is that there are or will be in the future large numbers of persons with demonstrable injuries or diseases resulting from exposure to hazardous substances who are not now being or will not in the future be compensated under current law.

We have to tell you that we are unable to find now in our loss and expense experience or elsewhere, any evidence that current legal remedies are failing to provide redress to persons eligible to make claims for injuries resulting from such exposures.

We will concede that in a few States what we regard as anachronistic statutes of limitations still pose procedural barriers to claims in long latency disease cases in the occupational and nonoccupational context. We are in the process of trying to overcome those barriers. We think that the statute of limitations should run from the time the disease manifests itself rather than from the date on which a given person was exposed to a hazardous substance.

In addition, we cannot and we don't know of anybody else who can determine how many persons who have a demonstrable injury resulting from exposure to hazardous substances are not availing themselves of remedies currently available. That is the great unknown. The anecdotal evidence we are able to come across, for example, the experience under California's Hazardous Substance Compensation Act, suggests that the number of people in this category is quite small. It leads us to suggest that more evidence that there are people out there with injuries who are not, one, pursuing the legal remedies that are available; and two, not recovering under those legal mechanisms, until there is firmer evidence on that point we would suggest that Congress stay its hand on any kind of compensation system.

We also think, looking further ahead, that Congress ought to be concerned about the insurability of those who might be required to fund any system the Congress ultimately creates. As no tax mechanism can, insurers distribute costs among their policyholders primarily on the basis of their loss history, thereby assuring that those who cause harm ultimately pay for it and providing a marketplace system for loss prevention incentives.

Unfortunately, virtually all the victim compensation the legislation proposed by Congress to date today is uninsurable. Whether these bills create a private cause of action, a nonfault compensation mechanism, or, worst of all, in our view, both, these bills to one extent or another would so weaken the evidentiary and burden of proof requirements in the common law as to cast upon defendants and their insurers what we view as the impossible task of identifying which of the millions of Americans with long latency diseases and other health problems did not contract them through exposure to hazardous substances and therefore are ineligible for compensation.

In much the same fashion as the 1976 Swine Flu Immunization Program did, these bills would so broaden the potential class of eligible claimants as to render our previous insured loss and expense experience essentially meaningless in trying to predict the costs that these bills would impose on industry.

Many of the pending proposals would dramatically weaken the common laws barriers to admissibility of irrelevant or highly prejudicial evidence on questions of disease causation. Some would not only permit the introduction of such evidence but also would allow that introduction to create a rebuttable presumption in favor of the claimant or plaintiff on the crucial disease causation issue.

Questions of fairness aside for the moment, consider the implications of these changes in the context of the manner in which most hazardous substance-related claims are likely to arise; that is, through surveillance that would typically result in discovery of an incremental increase in the historically expected morbidity or mortality from a given disease in a given locality.

If, upon investigation, a particular hazardous substance in the water supply were implicated in those excess illnesses or deaths, how would it be possible under this new system to determine which of the expected and unexpected or excess illnesses or deaths resulted from the ingestion of the substance?

For example, if the historical mortality from liver cancer of 100 persons per year increased by only 2 percent in a given locality and a hazardous substance in the local water supply were implicated in those excess deaths, only 2 of the 102 estates involved would be theoretically eligible to make a claim but in actual practice with reduced evidentiary rules, weakened standards of proof and a presumption of causations, it is going to be impossible to deny the claims from all 102 of those estates since all the decedents involved did ingest the substance.

The resulting overinclusivity of such a remedy, in our view, would be tantamount to a national health insurance system for all sufferers of long latency disease, and its costs would be beyond calculation.

If the costs of such an overinclusive system were imposed, through a tax, solely on those enterprises producing or handling hazardous substances, those enterprises would be required to internalize many times the costs of the harm they actually cause. This would not only be patently unfair but would so unhinge the relationship between responsible conduct and the imposition of liability as to make any industry's investment in loss prevention and safety research a waste of money.

The only plausible rationale, in our view, for a change in the current law is the observation by the study group that the difficulty and expense of bringing lawsuits make the tort system an inadequate remedy for persons who believe that their relatively minor injuries and/or damages resulted from exposure to hazardous substances. If it is the goal of the advocates of change to deal with the problem of potentially large numbers of persons with relatively minor losses, the tort system is the worst possible starting point for a victim compensation mechanism.

Yet virtually all the pending bills seek either to convert a fault-based system into a nearly nonfault compensation mechanism through corruption of its evidentiary and burden of proof requirements, or to piggyback the traditional tort remedy on top of a nonfault compensation program.

We have to tell you, from our experience with State no-fault auto insurance laws which sought to mate a nonfault approach to compensation with fault-based remedies, that the two systems are inherently incompatible. It is simply not possible to create an affordable system that will compensate all injured persons without regard to fault and give them the very generous damages that the tort system occasionally awards to some plaintiffs.

There simply has to be a choice. Either everyone receives limited benefits without regard to fault, or the few who prove another party at fault receive unlimited damages.

Unhappily, the Study Group's compromise approach would be nearly the most expensive of the conceivable options. Essentially, the study group recommended that claimaints be permitted to recover, under unbelievably lax tier I evidentiary and procedural rules, compensation for economic loss for which they have already been or easily can be reimbursed from private sources, and to turn the entire proceeds from these adminsitrative awards over to attorneys to finance tier II lawsuits for pain and suffering and other intangible damages.

If you don't mind, let me tell you exactly how this would happen. The study group recommended that only public sources of collateral benefits—Medicare, Social Security and the like—be deducted from tier I awards. Approximately 90 percent of all Americans have some form of health insurance, and the overwhelming majority of working Americans have employer-provided sick leave and wage continuation benefits. But under the tier I proposal of the study group, none of these benefits would be considered in calculating administrative awards.

Thus, if a typical American were to allege under a tier I proceeding that his disease was the result of a nonoccupational hazardous substance exposure and the defendant or a fund were unable to overcome a rebuttable presumption to this effect, the administrative agency would be required to award the claimant all his $10.000 in medical expenses and $5,000 in lost wages without consideration of the fact that his private health insurer would cover all the medical expenses and his employer would cover or already had covered most, if not all, of his wage loss.

Having received his administrative award of $15,000 and having turned his unpaid medical bills over to his health insurer, the tier I claimant could afford at no cost to himself to turn the entire award over to his attorney to finance the expert testimony and other expenses necessary to maintain a tier II lawsuit against a defendant who has already paid, either through taxes or subrogation, or both, the costs of the administrative award.

Since the study group proposed no limitation on a tier II plaintiff's ability to plead damages already reimbursed in tier I, recommending only that he be required to reimburse the tier I system for anything he recovers in tier II, and since the study group also recommended no variation in the traditional collateral source rule in the tier II proceeding, the plaintiff's lawyer in this case could plead the $15,000 already reimbursed by the tier I system as special damages or economic loss in the tier II lawsuit.

Now in most jurisdictions general damages—noneconomic loss, pain and suffering and the like—are calculated as a multiple of the special damages or economic loss involved in the case. So, looking at our hypothetical $15,000 in special damages, and assuming pain and suffering damages of five times those special damages, our well-financed plaintiff could win a tort judgment of $90,000, $15,000 in special damages, and $75,000 in general damages. Out of this judgment, the gratuitous $15,000 advanced by the tier I system would be reimbursed, the lawyer would take his one-third, or $30,000, contingent fee, and the plaintiff would pocket $45,000 tax-free and clear.

Now, if the tier I system were to require the deduction of all collateral sources of benefits paid or payable from administrative awards, and the statute were to prohibit the pleading in a tier II proceeding of benefits received from other collateral sources, the tier II picture would be quite different. In our hypothetical, the tier I claimant would be awarded only that portion of his medical expenses and wage loss not covered by his health insurer or his employer and would be able to plead none of these benefits as damages in a tier II proceeding, a fact that in our hypothetical would end the lawsuit before it began.

I mention this only to suggest that if the Congress believes what the study group assumed, that there are large numbers of persons suffering hazardous substance-related injuries too insignificant to make pursuit of a tort remedy economically feasible—and wishes to create an administrative alternative for these persons, we suggest that it consider building into that remedy two safeguards against its abuse: (1) the mandatory deduction of all paid or payable collateral benefits; and (2) a prohibition against introduction in a subsequent lawsuit of any damages reimbursed or reimbursable by any other source, including the administrative system.

In this fashion, the victim compensation bill could be limited to its intended purpose and prevented from becoming a back-door route to a national health insurance program or the greatest engine for tort litigation since the advent of the contingent fee.

A similar result could be achieved by requiring claimants to make an irrevocable election between the two remedies, so long as all collateral sources paid or payable are deducted from administrative awards.

We thank you for your consideration of our views.

[The statement of Mr. Cheek follows:]

STATEMENT OF LESLIE CHEEK III, VICE PRESIDENT-FEDERAL AFFAIRS, CRUM & FORSTER INSURANCE COS.

Mr. Chairman and members of the subcommittee, The Crum & Forster Insurance Companies are the Nation's fourteenth-ranked group of property-casualty insurers, with 1982 premiums of approximately $1.7 billion. We appreciate the opportunity to appear before you to discuss proposals to create new mechanisms for the compensation of persons alleging injuries or diseases resulting from exposure to hazardous substances.

As insurers, it is our chosen lot to collect and pool the funds that those subject to a variety of liability regimes will need to meet their legal obligations and that we need to fulfill our contractual obligation to defend our policyholders against third-party claims.

Our companies are among the largest writers of coverage for the principal non-fault system in the United States, workers' compensation, and of coverage for businesses subject to tort and environmental cleanup liability, Comprehensive General Liability (CGL) and Environmental Impairment Liability (EIL). We also write a substantial amount of insurance for vehicle owners in States with hybrid fault and no-fault systems of auto accident compensation. The lessons we have learned from our experience in servicing these liability and compensation schemes may be useful to the Subcommittee.

Our principal interest in any compensation or liability system is the predictability of its costs. Without reasonable certainty as to how many persons will make claims against the system, and how much on the average each claim will cost, we cannot determine the appropriate premium for the coverage we provide.

The Congress, too, must be sensitive to the predictability of the costs of any system it creates to deal with what we believe is a poorly defined and perhaps non-existent problem. Congress' last venture into a specialized compensation mechanism, the Black Lung Benefits Act of 1969, was initially estimated to cost less than $40 million per year. Costs under the Act are currently $2 billion per year.

The premise underlying the Superfund section 301(e) Study Group's proposals for new mechanisms to deal with hazardous substance-related claims is that there are (or will be) large numbers of persons with demonstrable injuries or diseases resulting from exposure to hazardous substances who are not being (or will not be) compensated under current law.

We are unable to find, in our loss and expense experience or elsewhere, any evidence that current legal remedies are failing to provide adequate redress to persons eligible to make claims for injuries resulting from exposure to hazardous substances. (In a few States, anachronistic statutes of limitation still pose procedural barriers to claims in long-latency disease cases in both occupational (workers' compensation) and non-occupational contexts, but the number of such States is dwindling rapidly.)

Indeed, our experience suggests that the success rate of claimants under both workers' compensation and the tort system in hazardous substance-related cases is improving steadily, as innovative counsel develop, and sympathetic courts adopt, new theories of liability. Case names that send shudders through underwriters' frames—*Borel, Sindell, Bichler* and *Beshada,* to list only four—are ample evidence of this trend.

But neither we, nor anyone else that we know of, can determine how many persons with demonstrable injury resulting from exposure to hazardous substances are not availing themselves of current legal remedies. Anecdotal evidence (e.g., the paucity of claims under California's 1981 Hazardous Substance Compensation Account) suggests that the number is extremely small, but the proponents of legislative change (e.g., the Superfund section 301(e) Study Group, the Environmental Law Institute) have assumed that the number is (or will be) large.

Insurers are prohibited by law and the demands of competition from basing their pricing decisions on speculation. While the past has not always been a reliable clue to the future, we have thus far survived looking only backward. We think the Congress would be wise to take a leaf from our book on hazardous substance compensation legislation, and postpone action until there is hard and consistent evidence that it is needed.

We also think Congress should be concerned about the insurability of those who may be required, in whole or in part, to fund any system it ultimately creates. Insurers apportion commercial insurance premiums among policyholders primarily on the basis of their loss history, thereby assuring that those who cause harm ultimately pay for it, and providing a marketplace incentive for loss prevention. An uninsurable system funded by a tax would be blind to variations in corporate conduct and would remove any incentive to invest in safety.

Moreover, an uninsurable compensation mechanism would be like a new car without an engine: it would look great, but it wouldn't get you anywhere.

Unfortunately, virtually all of the hazardous substance compensation proposals advanced in the Congress to date are uninsurable. Whether they create a private right of action, a non-fault compensation mechanism, or (worst of all) both, these bills, to one extent or another, would so weaken the evidentiary and burden of proof requirements of the common law as to cast upon defendants and their insurers the impossible task of identifying which of the millions of Americans with long-latency diseases and other health problems did not contract them through exposure to hazardous substances and therefore are ineligible for compensation.

In exactly the same fashion as the 1976 Swine Flu Immunization Program did, these bills would so broaden the potential class of eligible claimants as to render previous insured loss and expense experience useless to insurers trying to predict the costs the bills would impose on industry.

Beyond unpredictable costs, we see in many of the pending proposals a serious threat to efforts to prevent harm from occurring. To the extent that they would (1) compensate those who do not deserve to be compensated as well as those who do; (2) assess costs against chemical feedstock manufacturers and hazardous substance handlers with no regard for their conduct as corporate citizens; (3) abandon legal principles long regarded as fair and evenhanded; and (4) impose no controls either on the number of those eligible to recover or on the amount of individual recoveries, these proposals would entirely eliminate the incentives that most States' tort law provides to business to invest in safety and to prevent harm from occurring. Let me address each of these points.

First, overinclusivity. Many of the pending proposals would dramatically weaken the common law's barriers to the admissibility of irrelevant or prejudicial evidence on questions of disease causation. Some not only would permit the introduction of such evidence, but also would allow that introduction to create a rebuttable presumption in favor of the claimant or plaintiff on the crucial disease causation issue.

Questions of fairness aside for the moment, consider the implications of these changes in the context of the manner in which most hazardous substance-related claims are likely to arise—as a result of surveillance by the Centers for Disease Control (CDC) and/or the Agency for Toxic Substance and Disease Registry. Such surveillance would typically result in the discovery of an incremental increase in the historically expected morbidity or mortality rate from a given disease in a given locality. If, upon investigation, a particular hazardous substance in the water supply were implicated in the excess illnesses or deaths, how would it be possible under the new rules to determine which of the expected and excess illnesses or deaths resulted from ingestion of the substance?

Moreover, the smaller the incremental increase in expected morbidity or mortality, the larger would be the class of persons whose illnesses and deaths were plainly not caused by ingestion of the substance, but who, by virtue of the relaxed causation requirements, would be eligible for compensation. For example, if historical mortality from liver cancer of 100 persons per year increased by only two percent in a given locality, and a hazardous substance in the local water supply were implicated in the excess deaths, only two of the 102 estates involved would be theoretically eligible to make claims, but, in actual practice, it would be impossible to deny claims from all 102 estates, since all the decedents ingested the substance.

Under ordinary common law rules, the burden would fall on the members of the class to demonstrate, by a preponderance of the relevant evidence, which of the deaths, if any, resulted from disease caused by ingestion of the hazardous substance. Most of the class, and perhaps all, would be unable to sustain this burden. If none could, then perhaps injustice would result to the estates of the two decedents who might, in fact, have contracted cancer as a result of ingesting the substance.

Under some of the pending proposals, however, it would be the defendant's burden to show which of the 102 decedents he did not cause to contract cancer, and he would be required to rebut a presumption of causation arising in part from the mandatory admission of possibly irrelevant and perhaps prejudical evidence. If he could not overcome this presumption, then all 102 members of the class would recover, despite the fact that both they and the defendant know that 100 of them deserve nothing from the defendant. Is this not a greater injustice?

If you say it isn't, and that massive overinclusivity of the remedy is the price society must pay to make sure that the deserving two are compensated, then we submit to you that such a remedy would be tantamount to a national health insurance system for all sufferers of long-latency diseases, and that its costs would be beyond calculation.

We also submit to you that such a remedy would rob the chemical industry not only of its money and its capacity to compete in international commerce (and therefore to provide jobs), but also of any incentive to invest in safety research and technology, for "victim compensation" would bear no relationship whatsoever to harm actually caused by defendants.

If you say that such a system would be an injustice to defendants, but that deserving claimants should be compensated nonetheless, does that not suggest the absurdity of trying to convert the tort law from a mechanism for the adjudication of individual conduct into a mass compensation system?

Second, assessment of costs. The concept of cost internalization is based on the theory that the conduct of an enterprise can be favorably influenced by requiring it to absorb the costs of the harm it causes. The corollary of this concept is that the conduct of an enterprise can be unfavorably influenced by requiring it to absorb either more or less than the costs of harm it causes.

If the costs of an overinclusive "victim compensation" system were imposed solely on those enterprises producing or handling hazardous substances, those enterprises would be required to internalize many times the costs of the harm they actually cause. This not only would be patently unfair, but would so unhinge the relationship between responsible conduct and the imposition of liability as to make investment in loss prevention and safety research a waste of money. Is this really the price our society wants to pay for "victim compensation"?

Third, the abandonment of traditional legal principles. The premise of the Superfund Safety Group's characterization of the common law as "inadequate" in toxic tort cases was the assumption that difficulties in establishing proof of causation by the traditional preponderance of the evidence would prevent deserving claimants from recovering for their hazardous substance-related harm. We see no evidence to support this assumption in current toxic tort litigation.

But if one concedes, for the sake of argument, that there is some basis for this assumption, what should be done about it?

The Study Group correctly identified the problem of proving causation in toxic tort cases as a matter of science, rather than of law, but sidestepped the awkward, yet patently obvious, conclusion that dealing with the incapacity of most current scientific techniques to establish causal links between exposure and disease will take enormous amounts of both time and money. The Study Group instead proposed to paper over the evidentiary inadequacy of current scientific data by rigging the legal framework into which it would be introduced so as to give it presumptive legal weight in favor of claimants and to thrust upon defendants the burden of overcoming a presumption of causation.

Most of the pending bills adopt variations of this approach, and they would both encourage the debauchery of science by making even evidence which only "tends" to show causation admissible on that time issue, and debase the law by reversing the fundamental principle of our system of civil justice, that a defendant is presumed innocent until proved liable.

From an insurer's perspective, the more radically a statutory cause of action or compensation mechanism for alleged victims of "toxic torts" departs from traditional common law rules and procedures, the more difficult it will be for insurers to enter or remain in the market for environmental liability insurance.

Environmental tort liability is insurable, and insurance against such liability is currently affordable, primarily because the tort system does not compensate everyone who is injured merely because he is injured. A plaintiff must establish the defendant's liability by enough evidence to convince a judge or jury that it is more likely than not that the defendant's conduct was the proximate cause of the plaintiff's harm.

Except in the area of product liability, tort law is a seamless fabric, in that the same basic procedural and evidentiary requirements pertain in any claim, whether for automobile accidents or for hazardous substance injuries. A tug at the thread called burden of proof, undertaken to deal with a narrow range of potentially difficult claims, would undo the entire fabric, as enterprising lawyers beseech sympathetic judges to apply the precedent in other tort claims for the sake of restoring the tort law's traditional procudural uniformity.

Similarly, it is unrealistic to believe that liberal evidentiary rules in "tier one" of the Study Group's proposed system would not find their way into "tier two" tort claims, with totally unpredictable results.

No matter what legal mechanism is used to resolve toxic tort claims, the shortcomings of science will prevent the system from answering most causation questions with the certainty the law currently demands. And these shortcomings will never be fully overcome, not only because there is no one "cause" for most long-latency diseases, but also because of the sheer volume of chemicals in our environment and the moral infeasibility of treating humans as laboratory animals. But the prospect of imperfect scientific solutions to proof of causation problems should not become the basis for abandoning legal principles that our society has long regarded as fair and evenhanded. It seems to us that a higher priority should be given to bettering our understanding of human reactions to the chemicals in our environment.

We and others have repeatedly proposed, as an alternative to ill-advised tinkering with our legal system, the establishment and funding of a mechanism whose responsibility it would be to identify and document cause-and-effect relationships between certain durations and intensities of exposure to specific substances and the development of particular diseases. We are encouraged by the recent creation of the Agency for Toxic Substances and Disease Registry.

Fourth, and finally, controls on aggregate claim frequency or individual recoveries. The only plausible rationale for change in current law is the observation by the Study Group that the difficulty and expense of bringing lawsuits make the tort system an "inadequate" remedy for persons who believe their relatively minor injuries and/or damages resulted from exposure to hazardous substances.

The observation is correct, of course, but it is applicable to the victims of all kinds of injuries, not just toxic torts. The tort lawsuit is not, and was never intended to be, the vehicle for the resolution of all claims. Even among those who make use of it, only about half are awarded damages against defendants. Most tort claims are settled, with or without payment, outside the courtroom.

If it is the goal of the advocates of change to deal with the problems of potentially large numbers of persons with relatively minor losses, the tort system is the worst possible starting point for a compensation mechanism. Yet virtually all of the pending victim compensation proposals seek either to convert the fault-based system of tort law into a nearly non-fault compensation mechanism through corruption of its evidentiary and burden of proof requirements, or to piggyback the traditional tort remedy on top of a non-fault compensation program.

The plain goal of these proposals is to provide all hazardous substance victims with the best of both non-fault and fault-based remedies: eased evidentiary burdens coupled with generous awards. As laudable as this objective may be in theory, it cannot realistically be achieved if the system's costs are to be controllable, predictable, and, ultimately insurable.

We know, from experience with State auto insurance laws that sought to mate non-fault compensation programs with fault-based tort remedies, that the two systems are inherently incompatible. It is not possible, at one and the same time, to compensate all injured persons without regard to fault and to give them the generous damages that the tort system occassionally awards to some plaintiffs. There simply has to be a choice between the two extremes: either everyone receives limited benefits without regard to fault, or the few who prove another party at fault receive unlimited damages.

Unfortunately, the composition of the Study Group guaranteed not only that this necessary choice would not be made, but also that its "compromise" approach would be among the most expensive of the conceivable options. Essentially, the Study

Group's proposal would permit claimants with long-latency diseases to recover, under unbelievably lax "Tier I" evidentiary and procedural rules, damages for which they have already been reimbursed from private sources, and to turn the entire preceeds of their administrative awards over to their attorneys to finance "Tier II" lawsuits for pain and suffering and other intangible damages. Let me illustrate how this would happen.

The Study Group proposed that only public sources of collateral benefits—Medicare, Social Security disablility, State statutory disability income programs, etc.—be deducted from "Tier I" awards, and that "Tier II" tort plaintiffs be faced with the possibility of paying defendants' legal costs only if their tort damage awards were less than 125 percent of their administrative recoveries.

Approximately 90 percent of Americans have private health insurance protection, and the overwhelming majority of working Americans have employer-provided sick leave and wage continuation benefits. Under the Study Group's "Tier I" proposal, none of these benefits would be considered in calculating administrative awards.

Thus, if a typical American worker were to allege, under a Tier I proceeding, that his disease was the result of a nonoccupational hazardous substance exposure, and the defendant (or a fund) were unable to overcome a rebuttable presumption to this effect, the administrative agency would be required to award the claimant all of his $10,000 in medical expenses and $5,000 in lost wages, (assuming these were within the maximum permitted under the system), without consideration of the fact that his private health insurer will cover all of the medical bills and his employer will cover most, if not all, of his wage loss.

Having received his administrative award of $15,000, and having turned his unpaid medical bills over to his health insurer, the "Tier I" claimant can afford, at no loss to himself, to advance the entire award to his lawyer to finance (at no cost to the lawyer) the expert testimony and other expenses necessary to maintain a "Tier II" lawsuit for pain and suffering against a defendant who has already paid, through taxes or subrogation (or both), the costs of the administrative award.

Since the Study Group proposed no limitation on a "Tier II" plaintiff's ability to plead damages already reimbursed in "Tier I," (recommending only that a plaintiff be required to reimburse the "Tier I" system out of any tort proceeds), and no variation from the traditional "collateral source rule" in "Tier II" proceedings, the plaintiff's lawyer may plead $15,000 in "special" damages, or economic loss.

In most jurisdictions, "general" damages—pain and suffering and other non-economic losses—are calculated as a multiple of (anywhere from four to eight or nine times) "special" damages. Assuming general damages of five times special damages, our well-financed plaintiff could win a tort judgment of $90,000—$15,000 in special damages and $75,000 in general damages.

Out of this judgment, the gratuitous $15,000 advanced by the "Tier I" mechanism for expert witness and other costs of the lawsuit would be repaid, the lawyer would take his $30,000 contingent fee, and the plaintiff would pocket $45,000, tax-free and clear.

Now, if the "Tier I" system were to require the deduction of all collateral sources of benefits, paid or payable, from administrative awards, and the statute were to prohibit the pleading, in a "Tier II" proceeding, of any damages reimbursed by these sources or in a "Tier I" proceeding, the "Tier II" picture would be quite different.

In our hypothetical, the Tier I claimant would be awarded only that portion of his medical expenses and wage loss not covered by his health insurer or his employer, and would be able to plead none of these benefits as damages in a "Tier II" proceeding, a fact that would end the lawsuit before it began.

If the Congress believes what the Study Group assumed—that there are large numbers of persons suffering hazardous substance-related injuries too insignificant to make pursuit of a tort remedy economically feasible—and wishes to create an administrative remedy for these persons as an alternative to the tort system, we suggest that it consider building into that remedy two safeguards against its abuse: (1) a mandatory deduction of all paid or payable collateral benefits from administrative awards; and (2) a prohibition against the introduction in a subsequent lawsuit of any damages reimbursed or reimbursable by any other source, including the administrative system.

In this fashion, a "victim compensation" bill could be limited to its intended purpose and prevented from becoming either a backdoor national health insurance program or the greatest engine for tort litigation since the advent of the contingent fee.

A similar result could be achieved by requiring claimants to make an irrevocable election between the two remedies, so long as all collateral resources, paid or payable, are deducted from administrative awards.

We thank you for your consideration of our views, and would be pleased to answer your questions.

Mr. **Levitas**. Thank you, Mr. Cheek.

Ms. Birnbaum.

Ms. **Birnbaum**. Thank you, Mr. Chairman.

Mr. Chairman and members of the subcommittee, I appreciate the opportunity to speak with you this morning. I am here today representing the American Insurance Association, which is composed of more than 160 publicly owned insurance groups which presently provide the majority of general commercial liability insurance in the United States.

It is likely that the members of the American Insurance Association will be called upon to insure the defendants and manufacturers that will be caused to pay under any scheme of liability that is going to be adopted.

Mr. Cheek, I think, has explained some of the elements that the American Insurance Association believes must be considered in any compensation scheme. I think I have some expertise that might be helpful to the committee based on some of the questions the members have been asking and perhaps in my remarks I can leave my prepared statement and try to focus on some of the issues that I think are of great concern to this committee.

I have taught tort law at New York University Law School for nearly 10 years and I have participated in many of the types of toxic tort cases that are presently being litigated in the country. For example, I have participated in lead cases, and in cases involving DDT, DBCP, formaldehyde and other kinds of chemicals and drugs.

In my capacity as an academic and as a lawyer I have watched this area of the law develop from its infancy in 1973 with the Fifth circuit decision on the *Boree Asbestos* landmark case that set the parameters for determining a liability in toxic tort case.

Speaking in both capacities I think I can answer some of the questions that have been raised previously. Perhaps I can put this area in some sort of context for you from the defense point of view.

I think you have heard from Mr. Baron, the plaintiff's point of view; and from the questions—I wasn't present to hear the testimony—I think much of what he said would be reflected in my own testimony. That is the tort system, in so far as toxic torts are concerned is not broken and should not be tampered with.

I think one of the things that we all should do as lawyers and as Congressmen is give that system, which has worked so well in so many areas, an opportunity to resolve the problems in the toxic tort area. I don't believe that there are many victims out there—assuming they are injured—who are not able to get compensation through the tort system.

Let me give you some examples.

In New York there are the famous *Love Canal* cases. These are presently pending in Buffalo, NY with over 1,300 lawsuits being handled by very vew law firms who have built up enormous expertise in this area. Anyone in the Buffalo area who live around Love Canal dumpsite has available a legal remedy; many are already using the tort system to pursue that remedy.

Now we will have to see how those cases progress. At the moment they are in discovery. But if there is proof of causation—and that proof is being developed by plaintiffs' attorneys—and the people have been injured, there is presently in place a system that can provide adequate compensation. I believe we should use that system.

Another example of .how the system is operating is the *Agent Orange* cases. There is presently pending a class action in the eastern district of New York of potentially 2.5 million servicemen. That case is progressing and the court, under the common law system, will have an opportunity to resolve many of the issues of class action participation, and causation liability that the plaintiffs are presently advancing.

Mr. MOLINARI. Could I interrupt you please?

Ms. BIRNBAUM. Certainly.

Mr. MOLINARI. You made the statement that you see no reason to disturb the existing system because those who have been injured have been receiving recoveries. Then you go on to recite instances where there have been multiple plaintiffs who have instituted litigation which is in the pending stage.

Ms. BIRNBAUM. I am sorry; if I said that, I misspoke. What I intended to say is that the tort system is responding not only in these lawsuits that are progressing but also in other lawsuits which I can recite to you that have been settled or that have gone to verdict.

Mr. MOLINARI. Can you recite—I think it would be very helpful—could you recite cases reflecting extensive litigation? I am talking about large numbers of cases.

Ms. BIRNBAUM. Yes, sir.

Mr. MOLINARI. Litigated and recoveries? We would be happy to receive that.

Ms. BIRNBAUM. What I would like to do if I may is submit a written statement after this hearing where I can cite you to reported cases and to cases that have been settled, which are a matter of public record. I can give you some examples now, but I can certainly provide a much broader range of cases in a written admission. For example, there was recently a case in Idaho brought by children who had been living around lead smelters. That case was settled and payment of several million dollars was made to the children who had brought the claims.

A case brought by more than 1,100 plaintiffs was recently settled in Alabama. That case involved allegations of pollution from a DDT plant, was settled for several million dollars.

There have been many lead smelting cases that have been settled and substantial amounts of money have been provided. I can supply for the record other examples of these kinds of settlements that have occurred, some with great fanfare and some without great publicity. There was recently a case that went to trial and the verdict was over $50 million. The claim arose out of a chemical spill in which railroad workers were exposed to dioxin during the clean up efforts.

I might question the amount and reliability of these verdicts, but I think what these cases indicate is that there is a tort system presently in place, which is responding and which will continue to respond to claims. Until we find that the tort system is not working or not responding adequately to these needs of injured persons, I think we should not be tinkering with an entirely new system which will pose enormous administrative costs.

[The following was received from Ms. Birnbaum:]

COMPILATION OF SOME RECENT VERDICTS OR SETTLEMENTS INVOLVING EXPOSURE TO TOXIC SUBSTANCES

1. DIOXIN

Lowe v. *Norfolk & Western.*—Forty-seven railroad workers, alleging exposure to Dioxin while cleaning up a chemical spill, were awarded nearly $58 million by an Illinois state court jury. Three defendants had settled for $7 million the day trial was to begin. An appeal is presently pending in the Illinois Fourth District Court—Appellate Division.

2. LEAD

Bunker Hill.—On April 4, 1983, an Idaho state court approved a settlement awarding more than $23 million to 37 children. The children claimed that their health had been damaged due to lead emissions from the Bunker Hill smelter in Kellogg, Idaho (*Prindivill* v. *Bunker Hill Co. and Gulf Resources, Inc.*).

A similar suit in federal district court in Boise was settled in 1981 (*Yoss* v. *Bunker Hill Co.*). The settlement awarded nine children annuities and cash worth a total of about $7 million.

3. BENZENE

Lemaire v. *Texaco, Inc.*—A $4.3 million long term settlement was awarded in the Eastern District of Texas on January 8, 1982 to two shipyard workers and the widows of two former shipyard workers. The workers had contracted leukemia after cleaning barges and vessels of a chemical residue containing benzene.

4. PARAQUAT

Fereoee v. *Chevron Chemical Co.*—The family of a gardner who died of pulmonary fibrosis following exposure to the herbicide paraquat was awarded damages of $137,500 in the District Court of the District of Columbia on November 4, 1982. Appeal is presently pending in the District of Columbia Court of Appeals.

5. DDT

Olin Corp.—Parties in three suits (*Cloud* v. *Olin Corp., Freeman* v. *Olin Corp.* and *Erskine* v. *Olin Corp.*) reached settlement in the Northern District of Alabama as announced on December 27, 1982. The plaintiffs, residents of Triana, Alabama, claimed a higher than normal incidence of cancer and high blood pressure due to high concentrations of DDT near a former Olin manufacturing plant. The settlement was for $24 million, $19 million of which was earmarked for personal injury claims.

6. DBCP

Consolidated Chemical Exposure Cases.—Six chemical workers and three wives were awarded $7.9 million in compensatory damages by a California state court jury on March 14, 1983. The award held Dow Chemical Company liable for sterility of the workers due to exposure to the pesticide DBCP. A number of similar suits were settled out of court, as were claims against the University of California and one of its scientists.

7. FORMALDEHYDE

Alley v. *Gubser Development Co.*—On August 31, 1983, a couple alleging complication of a liver condition, respiratory problems, headaches and nausea due to inhalation of formaldehyde fumes in their mobile home, was awarded $50,000 in compensatory and $510,000 in punitive damages by a jury in Denver federal district court.

Boelens v. *Redman Homes.*—A Texas federal district court jury returned a verdict of $291,402 against a manufacturer and a retailer of a mobile home on April 27, 1983. The plaintiffs, a woman and her two daughters, claimed respiratory ailments and toxic hepatitis had resulted from inhalation of a formaldehyde present in their mobile home.

Lee v. *Service Insulation Co.*—In April, 1982, a settlement of $150,000 was reached in Oregon state court for a husband and wife who had sustained injuries upon inhalation of formaldehyde released from residential insulation.

Eckert v. *Guerdon Industries, Inc.*—A $600,000 verdict was returned in the District of South Carolina on January 12, 1982 for a woman who sustained lung damage through inhalation of formaldehyde in her mobile home.

8. CHEMICAL EXPLOSIONS

NL Industries.—NL Industries has agreed to pay between $500,000 and $1.2 million to each of four persons who had filed suits in the Southern District of Mississippi. The suits were filed after a June 2, 1982 chemical explosion killing three and injuring about 60 (*Price* v. *NL Industries, Spivey* v. *NL Industries, West* v. *NL Industries* and *Robinson* v. *NL Industries*).

Lara v. *Navaho Refining Co.*—On August 20, 1981 a landfill worker obtained a jury verdict of $335,632 for injuries caused by inhalation of methyl chloride gas produced by the explosion of chemical storage barrels.

Harrington v. *B.F. Goodrich.*—A settlement was recently reached for $1.25 million after a jury returned a $2 million verdict in favor of a rubber plant worker who allegedly contracted bladder cancer as a result of exposure to chemicals used in the manufacture of synthetic rubber.

Ms. BIRNBAUM. In addition, the tort system makes distinctions between good conduct and bad conduct, and I think this factor is very important. Ms. Hall made the comment that we really want to encourage and provide incentives to manufacturers to do the right thing. Well, I don't believe we do that by taxing them in a way that everyone pays according to the numbers of products they produce; rather than by holding liable only those who have acted poorly. In fact, it is the common law system that imposes punitive damages on those who have acted in gross and reckless disregard of human safety. In this way the tort system acts as to deter bad conduct.

We should be providing an incentive to companies to act promptly and responsibly, other than devising a means of holding everybody absolutely liable. Those who have done everything properly in depositing the chemical into a dumpsite will be held just as liable under an absolute liability system as those who have acted recklessly and criminally and may now even be out of business.

There is something about such a system that is unjust. I am not suggesting that there shouldn't be compensation for people who have been exposed and injured by toxic substances. What I am suggesting to you is that there is now a system in place to provide compensation and we should give that system an opportunity to develop; if it doesn't respond then perhaps maybe 5 years from now we will have to come back to the drawing board and consider whether we can do something.

[The statement of Ms. Birnbaum follows:]

STATEMENT OF SHEILA L. BIRNBAUM

Mr. Chairman and members of the subcommittee, I appreciate the opportunity to speak with you today as counsel representing the American Insurance Association. The American Insurance Association is composed of more than 160 publicly owned insurance companies providing property and casualty coverages—indeed, presently providing the majority of general commercial liability insurance in the United States. It is likely that the members of the American Insurance Association will be asked to provide insurance in the future for companies subject to liability to those who claim injury as a result of exposure to hazardous substances. The members of the American Insurance Association, and other insurers, have responded in the past to the emerging environmental liabilities; new coverages have been developed and competitively marketed. As Congress proceeds to investigate approaches to the compensation of victims of hazardous substance exposure, the American Insurance Association has an interest in seeing that the system as it develops is reasonable, equitable and insurable.

The general concerns of the American Insurance Association in this area have been made known to you through their position paper, dated July 12, 1983, which I understand you have already received. That position paper addresses comments both to the pending legislation generally, and specifically to certain recommendations made by the majority of the CERCLA section 301(e) Study Group.

I wish to focus my remarks today on two legal principles which form the centerpiece of the Study Group majority's recommendations: first, its recommended presumption that a disease or injury resulted from exposure to hazardous chemicals when no proof of that fact is available; and second, its proposal to use a formulation of strict liability which leaves no room at all for the traditional notion that a party at fault pays for the damage it causes.

THE PRESUMPTION OF CAUSATION

The Study Group majority recommended that in its proposed administrative proceeding, a claimant be afforded a presumption of causation upon a showing that his disease was of "the kind" which is "known" to be caused by a particular chemical to which he was exposed. The fund would be entitled to the same presumption in any subrogated proceedings to recover against a private company.

As a practical matter, this presumption makes private industry the guarantors of the health of large segments of the population at large. Many of the diseases which are alleged to be caused by hazardous substances—for example, cancer—are thought to have many possible causes. Claimants who can show that they were exposed to any particular carcinogen would be able to shift the burden the disease. Although the particular cancer might have been caused by other chemicals, smoking, diet, overexposure to sunlight, repeated irritation, or combinations of these and other factors, it would be all but impossible to prove that the particular chemical at issue did not cause this claimant's cancer. After all, the claimant, and not the defendant, is in possession of the facts concerning the onset of disease and the symptoms involved, personal diet and habits (such as smoking) that might be other causes of the disease, and all background information concerning the claimant's history and exposure to this or other hazardous substance. Yet despite claimant's possession of the relevant facts, the Study Group majority's proposed presumption would defy traditional principles of proof and place an impossible burden of disproof on the defendant.

As a result of this scheme, the defendant would be required to pay, not only for any cases of cancer caused by the release of the particular carcinogen, but also for all other cases of cancer that may arise from any other cause in the environment or even genetically. It has been estimated that approximately 2 percent (and no more than 5 percent of cancer deaths are caused by air, water and food pollution in all its forms; [1] 1 percent or less may result specifically from exposure to pollutants found in hazardous waste sites.[2] Thus, 95 percent or more of the damage payments that would be required to be made to those who have cancer and reside near a dump site, based on this presumption of causation, would be for cases not caused by any chemical released by the defendant.

Further, although the Study Group majority itself only recommended the use of this presumption of causation in proceedings for administrative awards and resulting subrogated proceedings by the fund to obtain indemnity from private companies involved, the likelihood is that this approach would find its way into the common law in time. Thus, in addition to medical expenses and lost earnings, pain and suffering awards would also be based on the presumption, despite the fact that a very large percentage of such awards should never be made because the injury or disease was really due to other causes.

This result is inequitable; it is also unwise. To fund what amounts to a social health scheme by loading the entire costs onto the chemical or oil industries—especially in the face of foreign competitors who are not burdened by such staggering costs—could prove disastrous to vital American industries.

Nat'l Cancer Inst. 1192, 1245–50, 1256 (1981); Technology Assessment Board, 97th Cong., "Assessment of Technologies for Determining Cancer Risks from the Environment," 91 (June 1981).

[2] Comments of Jim J. Tozzi at a conference on May 7, 1983 concerning Office of Management and Budget-sponsored Inter-Agency Study of Toxic Torts.

"STRICT LIABILITY"

The Study Group majority recommended that all consideration of fault be eliminated in assessing liability against defendants. This is a radical departure from traditional legal principles. Even under the principles of "strict liability" as applied today in many courts, and as embodied in the Restatement (Second of Torts) §§ 519-52, some evaluation of the conduct of the defendants remains an integral part of the decision of any court as to whether or not it should impose liability "without fault." The recommendations of the Study Group majority however, would not permit the courts or administrative tribunals to consider the good or bad conduct of the defendant and, therefore, would not encourage companies to act carefully in handling hazardous waste.

The traditional reasons for imposing liability on defendants who are in some way "at fault" are two-fold: (1) it comports without notions of fairness, and (2) it provides an incentive for the defendant and others to behave properly in order to avoid liability. A failure to consider conduct would remove incentives for industry to behave well. Under the Study Group majority's recommendations, the cost penalties would be assessed regardless, and so there would be no point (from industry's standpoint) in spending time or money "up front" to be careful or to act wisely. Such a result would be a national tragedy, since surely it is wiser to encourage industry to prevent harm in the first place.

This result is exacerbated by the Study Group majority's other recommendations. For example, the fact that a defendant can be jointly and severally liable without regard to fault, means that a very prudent manufacturer who merely had the misfortune to place its waste in the same disposal site as another company which acted recklessly, or even criminally, could nonetheless be held liable for the entire judgment. Given the operation of the Study Group majority's proposed presumption of causation, discussed above, a prudent manufacturer might be held liable even though the entire harm was caused by the missing, negligent manufacturer. If the negligent enterprise cannot be found, or is judgment proof, the prudent manufacturer will have no recourse for contribution or indemnity. Thus the care taken by the "good" company will be of no avail whatsoever.

Further, the Study Group majority suggested that the administrative recovery mechanism be funded initially by a tax on certain industries. Once again, such a tax would fall on the heads of "good" and "bad" actors alike, imposing huge financial burdens on private industry without providing any incentive for proper, careful behavior.

If Congress feels that there should be compensation for all injured persons who contract cancer or other diseases that might be caused by hazardous wastes, it should consider an effective method for doing so. The costs of these benefits ought not be levied in such a way as to leave no incentive at all for those who act responsibly. We have all benefited by obtaining the products, the high standard of living, and the relatively longer and healthier lives that modern industry and society have afforded. Although those who have negligently or recklessly disposed or waste products should certainly pay any victims who have been injured by their acts, the huge costs of a broad compensation scheme should not be placed on a small segment of American industry without regard to fault.

CONCLUSION

Our traditional legal principles have been based on concepts of justice and fairness. Any wholesale, radical abandonment of these principles runs the risk of seriously affecting the goals of justice and accident prevention that have been built into our tort law. The Study Group majority's recommendations are not only poorly thought out in the context of "toxic torts", as we have seen above, but they also run the distinct risk of weakening the overall fabric of tort law in other, unintended areas. I respectfully suggest that considerably more thought and care must be expanded by Congress, academicians and others before any solution to the toxic tort problem is adopted. Irresponsible "solutions" to our perceived problems may turn out to be worse than the problems they seek to cure.

V. CONCLUSION 40

I. INTRODUCTION

The American Insurance Association is a trade association composed of more than 160 publicly owned insurance companies providing property and casualty coverages. The Association's members provide the majority of general commercial liability insurance in the United States. It is likely that the members of the American Insurance Association will be asked to provide insurance for those subject to liability for hazardous substance compensation. A market for such insurance can develop only if the compensation liabilities to be insured are both reasonably predictable and affordable. The members of the American Insurance Association, and other insurers, have responded in the past to the emerging environmental liabilities; new coverages have been developed and competitively marketed. Thus, the American Insurance Association has an interest in seeing that the liability system as it develops is reasonable, equitable and insurable.

This Paper expresses the position of the American Insurance Association in response to state and federal legislative proposals concerning "hazardous substance" liability claims. Many of these bills are based in part on recommendations made by a majority of the

"Superfund Section 301(e) Study Group" (the "Study Group majority") in a Report dated September 1982 (the "Report") entitled Injuries and Damages from Hazardous Wastes -- Analysis and Improvements of Legal Remedies, submitted to the United States Congress pursuant to Section 301(e) of the Comprehensive Environmental Response, Compensation, and Liability Act of 1980 ("CERCLA"), P.L. 96-510.

II. EXECUTIVE SUMMARY

The law of torts, as implemented through our nation's courts, is the primary medium for resolving disputes as to compensation for claimants alleging injury from exposure to hazardous substances. The tort liability system as it has evolved over the centuries -- and as it continues to evolve today -- is designed to serve three functions: justice, compensation, and incentives for proper conduct. Ideally, a plaintiff will receive compensation in the courts only if it is just to require the defendant to pay, and if requiring such payments overall will tend to provide proper incentives for prudent behavior and to minimize the incidence and seriousness of such damage in the future.

Under traditional principles, a defendant whose fault or abnormally dangerous activity is determined to have caused an injury must compensate an injured claimant; such a determination is consistent with our notions of justice and fair play, and also serves as an incentive to that defendant and others, to do better in the future. Moreover, an injured plaintiff may not obtain compensation from parties randomly selected out of the general population who have not caused the injuries at issue and who have not engaged in any improper or abnormally dangerous activity; compensation is not provided in such a case because it would not be consistent with our notion of justice, would not penalize the parties actually at fault or encourage them and others to be more careful in the future.

The Study Group majority, and the sponsors of various bills subsequently introduced, have advocated radical departures from the present common law tort system to ease plaintiffs' burden of obtaining damages for personal injury or property loss allegedly resulting from exposure to certain hazardous substances. These proposals include devices such as:

1. A presumption that hazardous substances caused a plaintiff's injuries or disease where plaintiff cannot show that this is the case.

2. Absolute liability, without any regard to the presence or absence of fault on the part of the defendant.

3. The imposition of liability on a particular defendant far in excess of the harm that defendant caused, through the use of presumptions that a particular defendant's substance caused harm when no proof of that fact is available, and the use of joint and several liability.

4. The use of administrative remedies partially or completely funded by a tax on certain industries, which falls on good and bad actors equally and removes any incentives for proper conduct.

5. The imposition of retroactive liability.

6. The use of an administrative "compensation" scheme as an add-on to potentially unlimited tort liability, thus providing both widespread recoveries under relaxed standards of proof, and no limitation on the amount of recoveries that are available.

The American Insurance Association opposes such radical proposals because they detract from the combined ideals of justice, compensation and incentives for proper conduct that are the basis of the present tort system, and because it has not been demonstrated that such legislation is necessary or will improve the present system.

The proposals made thus far have the potential of providing awards for every case of cancer, tumor, genetic damage, and other diseases of the type claimed to result from "exposure" to hazardous substances. The cost of the proposed legislation would run into tens of billions of dollars per year for American industries -- a cost far in excess of any harm that has been demonstrated to be caused by hazardous substances, as opposed to the many other factors that affect our everyday lives and health.

Enactment of the specific proposals recommended by the Study Group majority and others, in addition to providing costly and unfair presumptions of causation not warranted by scientific or other evidence, would remove all incentives for industry to use due care in handling hazardous substances, since everyone would be penalized (through absolute, joint and several liability and through taxes) without any regard to fault or lack of fault. Thus the goal of preventing future harm would be abandoned in favor of an overbroad system of after-the-fact compensation. Moreover, the use of an add-on system of administrative recovery in addition to a system of unlimited courtroom recovery would constitute perhaps the most expensive and cumbersome compensation system that could possibly be devised.

The American Insurance Association believes that the proposals, which combine staggering costs, unlimited and unpredictable liability, and the abandonment of the traditional requirements of fault and causation, would be uninsurable, unaffordable, unjust and unwise.

III. THE STUDY GROUP MAJORITY'S RECOMMENDATIONS

Because most of the proposed legislation suffers from the same generic problems that are inherent in the Study Group majority's Report, a brief summary of the Report is included here.

The Study Group was comprised of twelve lawyers, three each appointed by the Presidents of the American Bar Association, American Law Institute, American Trial Lawyers Association, and the National Association of (State) Attorneys General. No medical, scientific, epidemiological, economics, industrial or underwriting experts were included in the Study Group.

The Study Group majority recommended that a two-tier recovery system be established. Tier One would provide an administrative remedy administered by the states but governed by federal law. (Report at 206).* Tier Two -- which would also be available even if a claimant first received a Tier One administrative award --

---

* Citations in this form refer to the pagination of Volume One of the Report as printed by the Government Printing Office, Serial No. 97-12. Volume Two contains lettered appendices to the Report.

would consist of the judicial tort-claim process, modified to make recovery of damages (including damages for pain and suffering, and punitive damages) far easier for plaintiffs.* Vehement dissents from these proposals were recorded in the individual comments of certain Study Group members, especially Chief Judge (ret.) Charles D. Breitel and George Clemon Freeman, Jr.**

Tier One

Tier One administrative remedies as recommended by the Study Group majority would permit recovery of full medical costs (without limit) and 2/3 of lost wages (up to a fixed monthly limit). Death benefits would also be paid to family members who had relied on the decedent for support. (Report at 206, 234).

Tier One administrative recoveries would be based in many cases upon a presumption of causation:

> "If the claimant in an administrative compensation proceeding proves:

---

* Through the use of joint and several liability, broader strict liability principles, liberal joinder rules and a more liberal statute of limitations. (Report at 255-60).

** Comments by Charles D. Breitel, Study Group Member (Report at 295); Comments of George Clemon Freeman, Jr. (Report at 305)

> 1) that the source involved in the claim was engaged at the time of exposure in the production, transportation or disposal of hazardous wastes; and
>
> 2) that the claimant was exposed to such hazardous waste by proximity, contact, ingestion, inhalation, or by some other form of exposure; and
>
> 3) that the claimant suffered death or the kind of injury or disease which is known to result from such exposure

then the following rebuttable presumptions should arise:

> (a) that the exposure to the hazardous waste generated, transported or disposed of, by or in the source, contributed to the death, injury or disease of the claimant; and
>
> (b) that the source by or in which such hazardous wastes were generated, transported or disposed of was responsible for the claimant's exposure and for the resulting death, injury or disease." (Report at 213-14 (indentation added)).

A claimant would not be required to demonstrate any fault on anyone's part in order to recover. (Report at 196, 209).

The Study Group majority made no study of the expected or potential costs of its proposed program. It did recommend that the fund out of which these administrative recoveries would be paid be provided initially through a tax on industry. (Report at 245). Further funding would be provided by subrogated agency claims against the owner, operator, generator, transporter, or other "alleged responsible party" after the agency had paid a claimant. (Report at 246). Such subrogated claims by the agency would be made on the same basis as a claimant's original claim -- i.e., including the presumption of causation and lack of any required proof of fault; subrogated claims would not require proof that an owner, operator, generator, or transporter, etc., knew or should have known of the hazard. (Report at 246-47). Thus, a defendant's liability would be nearly absolute.

Tier Two

A Tier One administrative award would not bar a claimant from pursuing further damages in court under Tier Two. The agency granting a Tier One award would be reimbursed from any court award. The Study Group majority recommended that the courts be empowered to assess costs against a plaintiff who had previously obtained an administrative award, if the plaintiff failed to receive an award in court at least 25% larger than that granted by the agency. Such cost assessment, however, would not be mandatory. (Report at 197-98).

The Study Group majority recommended that the judicial process adopt a very liberal statute of limitations (based not only on discovery of the injury or disease but also on discovery of the cause of the injury or disease), liberal joinder rules, and joint and several liability for each defendant who has "contributed" to the injury, above some de minimis level. (Report at 255-58).

IV. DEFECTS IN THE PROPOSALS

A. Proponents' Failure to Demonstrate a Need for Radical Change

The proposals of the Study Group majority and others have been put forward despite the complete absence of evidence that large groups of plaintiffs exist with injuries caused by hazardous substances who will not be compensated by the present common law tort system. In the absence of any such showing, the American Insurance Association opposes legislation that would so radically alter traditional common law remedies and would render uninsurable those who would be subject to the new liabilities.

The lack of any reliable scientific basis underlying these calls for legislative reform is admitted in the Report:

> "The discussion of legal issues relating to injuries from hazardous wastes must proceed in a setting of factual and scientific uncertainty because, at this time, in mid-1982, it is impossible to determine the number of persons who

> have been injured or who could be injured by exposure to such sites." (Report at 21, footnote omitted).

Study Group Member George C. Freeman, Jr. in a letter dated March 2, 1982 (included in Volume Two of the Report) noted:

> "We have very little reliable information about how much truly toxic wastes are out there and how many persons may or may not have been exposed to them in circumstances that have caused, or are likely to cause, death, serious bodily injury or disease.
>
> * * *
>
> If relatively few people have in fact been injured by (or even exposed to) toxics, the fact that few cases for damages have been successfully brought should not be regarded as evidence that the current law is inadequate or unfair." (Id.)

Premature public outcry is not unprecedented in the field of hazardous substance legislation. In 1980 the Environmental Protection Agency released a study purporting to show chromosome defects among residents near the Love Canal. Based in large part on this study, more than 700 people were evacuated from the area by the federal government; a public outcry was launched and CERCLA was passed later the same year. Subsequent reports, however, reveal that this study "was so poorly designed that it should never have been undertaken."* A subsequent study released on May 17, 1983, by the Centers for Disease Control found no increase in chromosomal abnormalities among Love Canal residents (including 17 such residents who had participated in the original study) when compared to a comparable control group.** This newest study also noted that other "[e]xtensive studies at the Love Canal dump site in Niagara Falls, New York, giving particular attention to reproductive abnormalities and to cancer, have thus far defined no firm evidence of increased disease incidence or mortality . . . ."***

---

* Boffey, "Study of Love Canal Finds No Direct Link to Genetic Disease", New York Times, May 18, 1983, at A1, col. 6. No comparable control group was used in the original study.

** Centers for Disease Control, Brookhaven National Laboratory & Oak Ridge National Laboratory, A Study of Cytogenic Patterns in Persons Living Near the Love Canal (hereinafter "CDC Study"); see "Study of Love Canal Finds No Direct Link to Genetic Disease", New York Times, May 18, 1983, at A1, col. 6. See also Dionne, "U.S. Finds Love Canal Neighborhood Is Habitable," New York Times, July 15, 1982, at A1, col. 1.

*** CDC Study at 1. Similarly, there is no evidence that the tort system has failed in the oft-cited Environmental Law Institute study entitled Six Case Studies of Compensation for Toxic Substances Pollution: Alabama, California, Michigan, Missouri, New Jersey, and Texas (Senate Comm. on Environ. and

(Footnote continued)

Given this background, legislatures should be cautious and not rush headlong into enacting overbroad "reforms." For example, in September 1981 the State of California established a Hazardous Substance Compensation Account (Cal. Health & Safety Code §§ 25300-95) to provide compensation "for loss caused by a release, in California, of a hazardous substance" if the release was from an unknown source or an unknown liable party, or if the liable party could not be found, or was judgment proof. As of March 1983, not a single direct claim had been asserted against the fund.* Despite publicity concerning the lack of claims made against the fund,** at

---

(Footnote *** continued from previous page)
Public Works, 96th Cong., 2d Sess., Serial No. 96-13, Comm. Print, June 1980) (hereinafter "Six Case Studies"). Of the six cases studied -- which six were chosen specifically because they were believed to demonstrate "substantiality of harm" and not on any random basis -- only two included any evidence of serious personal injuries due to chemical exposures, and certain injured persons received compensation in each of those two instances. This two-month study heavily reflected the personal views of the authors, but failed to afford those views an evidentiary support.

* See Hazardous Waste Management Council, Compensation: An Analysis of Hazardous Waste Facility Insurance Requirements and Alternatives 28 (January 1983).

** "California Cleanup Fund Has Money Begging," New York Times, Monday, March 21, 1983, at A12, col.6.

the present time less than a dozen claims have been filed.

In view of these facts, North Carolina has recently adopted a more cautious approach. The 1982 Annual Report and Special Reports of the North Carolina Governor's Waste Management Board, while recommending certain limited changes in the application of strict liability principles under the tort law system, rejected an administrative remedy or any presumption of causation. (_Id._ at 53-56). With respect to administrative remedies:

> "The Board concluded that it is premature at this time to assume that the volume or complexity of hazardous waste liability cases will be so great that the general court system cannot handle them adequately." (_Id._ at 56).

B. Proponents' Failure to Consider the Staggering Costs of Their Overinclusive Proposals

It would be disastrous to structure a radical new "solution" in such a way as to eradicate the traditional tort law requirements that a plaintiff show a defendant was at fault and caused the harm complained of.* Such a "solution" would, in effect, require the chemical and oil industries to pay the costs of cancers, tumors, genetic damage, joint pains, headaches and other diseases or symptoms every time a claim of "exposure" to toxic waste was lodged, even if (as would almost always be the case) the claimant's disease resulted from a combination of other causes such as normal environmental or genetic factors unrelated to exposure to toxic waste. (See further discussion of the specific legal principles below).

---

* Moreover, any "solution" that abandons these elementary principles might have serious ramifications for tort law in other areas, which no one intended to "reform."

For example, consider the present cancer statistics - just one disease that _might_ result from exposure to hazardous substances. In 1983, an estimated 440,000 Americans will die of cancer, and an estimated 855,000 people will be diagnosed as having cancer.* Statistics show that more than 20% of the total deaths among Americans resulted from some form of cancer -- the second highest cause of death, after heart disease.** Yet, it has been estimated that approximately 2% (and no more than 5%) of cancer deaths are caused by air, water and food pollution in all its forms;* 1% or less may result specifically from exposure to pollutants found in hazardous waste sites.** However, the Study Group's proposal, echoed in many of the pending legislative proposals, would permit recovery by anyone who can claim non-occupational "exposure" to hazardous waste dumps and whose ailment cannot be demonstrated _not_ to have resulted from such exposure -- an impossible burden for a defendant to meet, as more fully discussed below. Such a skewed system would certainly involve many times the number of recoveries than would be warranted by the small percentage of diseases arguably "caused" by hazardous substances.

---

* E. Silverberg & J. Lubera, _Cancer Statistics, 1983_ 10 (reprinted from _Ca-A Journal for Clinicians_, Vol. 33, No. 1, 1983 (American Cancer Society).

** Figures for 1978 (the last available year). _Cancer Statistics, 1983_, _supra_, at 11.

In light of these facts, the cost of the Study Group majority's overinclusive "solution" would be staggering. Just as with other types of compensation programs begun in the 1960s and early 1970s the costs can be expected to balloon to truly massive proportions. See "Toxic-Liability Bills Plant a Time Bomb of Entitlement Costs," The Wall Street Journal, Friday, June 3, 1983, p. 20, col. 3; Office of Management and Budget, Compensation for Toxic Substances Exposure (May 19, 1983). The experience under the federal Black Lung Benefits Act provides an apt warning:

---

* _See_ R. Doll & R. Peto, _The Causes of Cancer: Quantitative Estimates of Avoidable Risks of Cancer in the United States Today_, 66 J. Nat'l Cancer Inst. 1192, 1245-50, 1256 (1981); Technology Assessment Board, 97th Cong., _Assessment of Technologies for Determining Cancer Risks from the Environment_ 91 (June 1981).

** Comments of Jim J. Tozzi at a conference on May 7, 1983 concerning Office of Management and Budget-sponsored Inter-Agency Study of Toxic Torts.

> "The Black Lung Act provides an example of what can happen when a compensation system is not well thought out. A General Accounting Office report issued in January 1982 found that 84 percent of claims were paid without adequate medical evidence.
>
> The result: In 1969, Congress estimated that the total program would cost between $40 million and $385 million. By 1972, costs to the federal government alone amounted to $33 million per month. In 1979, such costs amounted to $1.5 billion and reached $2 billion in 1982. The total cost of the program, including benefits paid directly by industry, is unknown."*

As a result, in 1981 Congress eliminated many of the presumptions of causation in the Black Lung Act because they had "led to an excessive number of claims and vastly greater expenditures than had been anticipated." (Report at 228). Black Lung Act costs are expected to level off or slightly decrease over the next few years.* Nonetheless, one critical presumption remains -- a rebuttable presumption that certain identified diseases were work-related if the employee could show 10 years of employment. Consequently, costs will not decline very quickly, and in fact continued to rise in 1982.**

---

* J.B. Browning (Chemical Manufacturers Association), Public Compensation: A Chemical Industry Perspective 9 (April 5, 1983); see Problems Relating to the Insolvency of the Black Lung Disability Trust Fund: Hearings Before the Subcomm. on Oversight of the Comm. on Ways and Means of the House of Representatives, 97th Cong., 1st Sess. 2-15, 159-88 (1981).

The Black Lung Act is very limited in scope; costs for a sweeping hazardous substance program would be enormous, given the broad presumptions, unlimited awards and huge administrative costs inherent in the pending proposals.

To obtain a rough concept of this cost, assume that the number of cases that would be filed for all the types of diseases which plaintiffs may claim could result from exposure to hazardous substances -- cancer, respiratory ailments, tumors, genetic defects, coronary disease, etc. -- might be so low as one-fourth of the diagnosed annual number of cases of cancer alone. Rounding downwards, such an assumption yields an incidence of approximately 200,000 claims filed per year.*

---

* Office of Management and Budget, Compensation for Toxic Substances Exposure, Chart 2 (May 19, 1983).

** Id. Further, the use of a presumption that a disease is work-related in the context of the Black Lung Act or workers' compensation statutes is inherently a limited one; the list of employees on the roster is finite and easily ascertainable. Such a presumption relating to hazardous substance exposure is open-ended, uncontrollable and potentially limitless in scope.

At this conservatively estimated rate of claims, and given the same average recovery in Tier One that is estimated for current workers' compensation cancer cases of $130,000 per award,** the Study Group's program would result in an annual cost of $26 billion in Tier One claims payments alone.*** Assuming allocated loss adjustment expenses (i.e., defense legal fees, etc.) of approximately 10% added to the total cost of these cases,* the annual bill in Tier One alone might be on the order of approximately $28 billion.

---

* In view of the claims of the Environmental Protection Agency ("EPA") and legislative proponents, this number of cases is entirely within the bounds of possibility. EPA has claimed there are over 80,000 sites in the nation with contaminated surface impoundments, 90% of which "are believed to pose at least a potential threat of ground water contamination." Technology Assessment Board, 98th Cong., Technologies and Management Strategies for Hazardous Waste Control 5 (March 1983). Under the Study Group majority's approach, residents around these sites showing "exposure" may be able to recover, even where such "exposure" did not actually cause their disease or injury.

** Source: National Council on Compensation Insurance. See Technical Appendix A.

*** I.e., 200,000 claims times $130,000 per award. To put this annual cost in perspective, it represents more than twice the total workers' compensation loss and loss expense incurred by private carriers and state funds in 1981 (almost $12 billion), and would (Footnote continued)

Additional awards to plaintiffs in Tier Two would add massive costs such as pain and suffering awards, attorneys' fees and litigation expenses. To the extent this estimate is conservative in its assumptions, it follows that the actual cost of the program will run even higher.

To require that this extraordinary cost -- far in excess of any proven level of injuries caused -- be shouldered by a few American industries would seem very

---

(Footnote *** continued from previous page) add 7.0% to the inflation rate of chemical and petroleum product prices (given 1982 sales of $371 billion), along with a similar effect on the prices of all other goods and services that incorporate these products, if an industry tax were passed through to consumers.

* The National Council on Compensation Insurance figures showed allocated loss adjustment expenses of 10%, but it is reasonable to expect that for cases proceeding on through Tier Two litigation, such expenses would be three to four times higher. The Study Group majority's proposal provides no abatement in these transaction costs, since plenary court lawsuits are not barred; indeed, the Study Group's proposal merely adds the administrative costs to the present system.

unwise, especially in the face of foreign competition which would not be burdened by similar costs. See Letter dated March 10, 1982 by Study Group Member George C. Freeman, Jr. (included in Volume 2 of the Report). In addition, as the cost of complying with the law rises, the incentive to engage in illicit, secret dumping or to employ other illegal means of waste disposal rises.* Further, to assume that such an extraordinarily costly scheme is insurable, or worse yet to dismiss the issue with the Study Group majority's assertion that:

---

* Concern has already been expressed that organized crime may be involved in the garbage and waste disposal industry. See, e.g., "Corruption Cited in Waste Business," New York Times, Sunday, May 1, 1983, at A52, col. 4; "Attorney Denies Dumping, Mob Connection," UPI Regional News story, Friday, April 29, 1983; "Poison Dump Stirs Alarm in Poconos," New York Times, Sunday, April 24, 1983, at A20, col. 1. As the New York Times reported last year in connection with the conviction of Russell W. Mahler:

> "New York can handle only 60 percent of the 1.4 million tons of industrial waste that companies in the state produce annually, and the pressure to get rid of some of it by illegal means is tremendous, according to state officials. 'If you pay the price, you can dispose of hazardous waste, but the price can be prohibitive,' said Jeremiah B. McKenna, counsel to the State Senate's Select Committee on Crime."

Chavez, "Toxic Waste Entrepreneur," New York Times, Thursday, May 27, 1982, at D1, col. 1.

> "insurability is not the sole or even the dominant factor that ought to determine whom the law protects and how,"*

is to court disaster. If no insurance were written to cover these risks, or if industry is unable to afford the premiums, there would be no effective means of spreading the enormous cost of the proposed system while at the same time offering the incentives to careful conduct that are traditionally provided by variable commercial insurance rates. Without insurance, it is unclear that our vital industries would even be able to meet this level of risk without jeopardizing their very existence. Unfortunately, this is precisely the perilous course which the Study Group majority, and proposed state and federal legislation modelled on its recommendations, would have us adopt.

---

* Report at 185. See Letter dated May 17, 1982 from George C. Freeman, Jr. (included in Volume Two of the Report), which questioned the availability of insurance to cover the Study Group's proposals.

C. Proponents' Failure to Consider the Ramifications of the Specifics of Their Proposals

1. The Presumption of Causation

The heart of both the Study Group's Report and many of the legislative proposals introduced is a presumption that diseases contracted by an "exposed" person were caused by that exposure. But in fact, such diseases have a multiplicity of possible causes, of which hazardous substance exposure may be one of the least significant when compared with diet and certain habits (such as smoking).* The Study Group majority's attempt to legislate science, without regard to the actual facts that are available, is echoed in the vast majority of the bills that have been submitted to state and federal legislatures.**

---

* *See* R. Doll & R. Peto, *The Causes of Cancer: Quantitative Estimates of Avoidable Risks of Cancer in the United States Today*, 66 J. Nat'l Cancer Inst. (1981); Technology Assessment Board, 97th Cong., *Assessment of Technologies for Determining Cancer Risks from the Environment* (June 1981).

** *See*, *e.g.*, Massachusetts H. 5179, § 7(a); S.917, § 5(c)(3); S.946, § 3(b); H.R. 2330, § 102(a); *cf*. Minn. Stat. § 115B.07. Indeed, Senator Mitchell's proposal in S.946, after providing a "rebuttable presumption", goes on to state:

> "Evidence as to the physical weakness or personal habits of the individual on whom

(Footnote continued)

It may be impossible for a defendant to prove lack of causation from an exposure, given the long latency period for many toxic waste related diseases. Plaintiff, and not defendant, is in possession of all the facts concerning the onset of disease and the symptoms involved, personal diet and habits that might be the cause of the disease, and all background information concerning plaintiff's history and exposure to this or other hazardous substances. None of this information is public, unlike much of the information about hazardous substances in dump sites collected by the federal government under CERCLA. See, e.g., 42 U.S.C. § 9603(c).

Given ordinary human sympathies, a burden to disprove causation would be much harder for a defendant to sustain than it would be for a claimant to prove causation affirmatively. Thus, industry members would become virtual guarantors for the costs of all diseases and

---

(Footnote ** continued from previous page)
the claim is based shall not be used to rebut the presumption created by this paragraph."

Thus, for example, a person who contracted lung cancer after an exposure to hazardous substances would presumably recover under this formulation on the basis of the exposure, no matter how heavy a smoker he is. Smoking, however, might be many times the more significant contributory factor.

genetic defects occurring in an indeterminate population that lives, works, and vacations in, and perhaps even passes through, the vicinity of every hazardous waste site, without any real regard for whether the harms claimed were actually caused by the hazardous substances, or whether they resulted from or were primarily contributed to by other causes.

Insurance industry representatives and members of the Study Group itself also expressed concern that, despite a lack of any recommendation so providing, the presumption of causation available to claimants in a Tier One administrative proceeding would likely be imported into Tier Two by the courts,* resulting in full recoveries (including pain and suffering damages) to a large number of plaintiffs without proof of causation. This concern is heightened by examples such as the Minnesota Environmental Response and Liability Act (the "Minnesota Act"), passed in May 1983, which provides in Minn. Stat. § 115B.07 for restrictions on directed verdicts -- a provision that amounts in practice to a presumption.* This de facto presumption is by its terms made applicable to actions brought under the Minnesota Act "or any other law to recover damages for death, personal injury, or disease arising out of the release of a hazardous substance . . . ." Id. (emphasis added).

---

* Report at 175, 264-65; Comments of Study Group Member Charles D. Breitel (Report at 300); Comments of Study Group Member George Clemon Freeman, Jr. (Report at 318).

2. Liability Without Regard to the Defendant's Fault or Lack of Fault

The Study Group majority recommended that all consideration of fault be eliminated entirely in both Tier One and Tier Two proceedings.** Even the attenuated fault concepts embodied in the "strict liability" provisions of the Restatement (Second) of Torts § 519-52 would be disregarded by the Study Group majority.

---

* Minn. Stat. § 115B.07 prohibits a directed verdict for the defendant on the issue of causation if plaintiff "produces evidence sufficient to enable a reasonable person to find that" (a) the defendant is responsible for the release of the hazardous substance; (b) the plaintiff was exposed; (c) "the release could reasonably have resulted" in the amount and duration of plaintiff's exposure; and (d) "the death, injury, or disease suffered by the plaintiff is caused or significantly contributed to by exposure to the hazardous substance in an amount and duration experienced by the plaintiff." The statute continues:

> "Evidence to a reasonable medical certainty that exposure to the hazardous substance caused or significantly contributed to the death, injury or disease is not required for the question of causation to be submitted to the trier of fact." Id. (Emphasis added).

** Report at 196, 209, 260, 265-66.

The Second Restatement applies a strict liability standard to abnormally dangerous activities. At the same time, it:

> "cautions against defining a type of activity as 'abnormally dangerous' in and of itself, however, and advocates considering the activity in light of surrounding circumstances on the facts of each case. This, in essence, shifts consideration from the nature of the activity to the nature and extent of the risk."

Clark-Aiken Co. v. Cromwell-Wright Co., 323 N.E.2d 876, 887 (Mass. 1975) (stated with respect to the Tentative Draft of the Second Restatement). Section 520 of the Second Restatement provides:

> "In determining whether an activity is abnormally dangerous [and thus gives rise to strict liability], the following factors are to be considered:
>
> (a) Whether the activity involves a high degree of risk of some harm to the person, land or chattels of others;
>
> (b) Whether the gravity of the harm which may result from it is likely to be great;
>
> (c) Whether the risk cannot be eliminated by the exercise of reasonable care;
>
> (d) Whether the activity is not a matter of common usage;

(e) Whether the activity is inappropriate to the place where it is carried on; and

(f) The value of the activity to the community."*

Thus, the Second Restatement requires a court to consider whether an activity is necessary to society and is being carried on in an appropriate location, among other things, before finding it to be "abnormally dangerous" and imposing "strict liability" for injuries that result from such an activity.

The Study Group majority, however, would impose strict liability without first considering all the circumstances. The Study Group majority stated:

> "Formulations of strict liability that balance the hazard of the activity against its utility and its appropriateness to the locale import considerations of negligence that entail significant barriers to the recovery of damages for injuries from exposure to hazardous wastes. To remove these barriers, the application of a theory of strict liability is needed that focuses on the nature of the hazardous waste activity itself, and on the magnitude of the risk." (Report at 260).

The trend in tort law today is not toward absolute liability such as was recommended by the Study Group majority, but rather toward more limited "strict liability" concepts based on the Second Restatement.* Today the overwhelming majority of states that have considered Section 520 of the Second Restatement have utilized its factors in determining cases.**

---

* Under the case law, disposal of hazardous waste has not uniformly been found to be abnormally or inherently dangerous. See Ewell v. Petro Processors of Louisiana, 364 So.2d 604 (La. Ct. App. 1978).

This acceptance of the Second Restatement's factors is based upon sound considerations. These same factors are, in part, the criteria used by underwriters to determine insurance premium rates for a particular insured. Absolute liability, without any regard to proper conduct, on the other hand, leaves no room for consideration of fault, and provides no incentive for companies to behave well in handling their hazardous substances. An absolute liability system would penalize necessary industries conducted in a reasonable manner just as heavily as marginally useful, irresponsibly conducted activities; careful conduct would become irrelevant. The balanced approach of the Second Restatement should not now be abandoned in favor of an ill-considered stampede to an absolute liability standard.

Super. 210, 440 A.2d 455 (App. Div. 1981).

3. Imposition of Excessive Liability on Non-Responsible Defendants

The use of absolute liability without regard to fault is particularly far-reaching in light of the Study Group majority's recommendation that defendants be jointly and severally liable in a court proceeding. (Report at 257-58). Thus, a very prudent manufacturer who merely had the misfortune to place his waste in the same site as another, who acted intentionally or even criminally, could be held liable for the entire judgment. If the negligent enterprise cannot be found, or is judgment proof, the prudent manufacturer will be forced to bear the entire liability without recourse despite careful and proper behavior.

This situation is exacerbated further by the presumption proposed by the Study Group majority. Under that presumption, for example, a claimant might simply prove his exposure to "Substance X" and that a particular manufacturer deposited "Substance X" in the dump site the claimant asserts is the source of the contamination affecting him. In a subrogated liability proceeding against the manufacturer, liability would be found unless the manufacturer meets a burden of showing that somebody else's "Substance X" was the source of the contamination. If there was a lack of historical evidence, as may often be the case, such a burden could not be maintained. Thus, a perfectly prudent, careful and non-responsible party who dealt in "Substance X" might ultimately bear a liability for harm it never caused, but which was instead caused by the irresponsible activities of another person. The unpredictability of this liability, coupled with its potentially huge amount, would make it extremely difficult to insure.

4. The Initial Funding Tax and Further Removal of Incentives for Careful Handling of Hazardous Substances

The proposal that a compensation program should be initially funded through taxes on industry* would place an impossibly high burden on domestic industries already faced with stiff foreign competition unburdened by such expenses. See Comments of Study Group Member George Clemon Freeman, Jr. (Report at 311-14). Funding by such a generic tax burden prevents an enterprise from reducing its cost by prudent behavior.

> "The Study Group claimed that the costs of injuries should be carried by the industry or enterprise that creates them 'because efforts to reduce the cost will result in greater care, more safety and protection of the public' . . . [see Report at 248]. Though this generalization is often true, it is an inappropriate justification of the proposed tax.
>
> The Study Group's rationale is wrong on at least two counts. First, a tax on industry output provides little or no incentive for any single enterprise to reduce its liability. A firm does not reduce its tax burden by taking due care to avoid hazardous waste damages; therefore, such a funding mechanism simply does not act as a deterrent. Secondly, the fund is only applied to exposures that have either happened in the past or for which there is no responsible party; obviously, it is impossible to deter this type of exposure and, consequently, the tax provides no appropriate incentives. . . ."**

---

* Report at 245.

(Footnote(s) ** will appear on following pages)

Such a tax would eliminate the use of commercial insurance, thus further removing any incentive to handle hazardous substances properly, and eliminating a valuable social mechanism of industrial self-regulation.

Insurance is a method of assessing and spreading risk, which has proven to be efficient in determining proportionate potential liability. Each insurer, in competition with all other insurers, puts itself at risk based upon its determination of an insured's potential liability. Using underwriting criteria that include not only statistical data but also loss control and loss prevention expertise, an insurer makes a determination as to which facilities or activities it will insure. In so doing, insureds that may treat or deal with the same quantity and type of toxic substances may be charged different premiums for their coverages because of judgments made by underwriters that reflect tangible and intangible qualities ranging from record keeping, to attitude toward loss control, to the level of personnel dealing with loss control and prevention.

** National Economic Research Associates, Inc., The Role of Economics in Tort Law Reform, (Draft Memorandum by F. Dunbar), at 10-11 (November 8, 1982).

Myriad factors, together with the personal experience of the underwriters, will determine the effectiveness of the underwriting process. This process is totally unlike a tax system, which treats the facilities disposing of the same or similar quantity or type of toxic substance in an identical manner, as though they were identical. The insurance mechanism, operating in conjunction with a sound tort system, provides carefully honed financial incentives to proper behavior and injury prevention, which can never be duplicated by a tax-based system.

5. Retroactivity

> "[I]f regulation under RCRA is effective, there is hope that there will be few cases of injury from hazardous waste in years to come. The recommendation for the compensation remedy is based on the possibility and concern that past hazardous waste disposal practices may have created a backlog of injuries and exposures that the legal system will need to clean up." (Report at 195).

With these words, the Study Group majority focused its attention on the issue of retroactive liability, relying heavily upon the speculative "possibility" that past practices "may have created" an as yet unidentifiable "backlog" of cases for the legal system to "clean up."

The pitfalls for the insurance industry of creating new, massive, retroactive liability for past practices are well known. The imposition on insurers of new obligations beyond those contemplated by the parties to the insurance contracts could be devastating to the entire insurance industry. Insurers have collected their premiums and set aside reserves based upon the law as the parties understood it at the time of contract. It is neither just nor sound practice to expand these obligations by legislative fiat. Further, as to future underwriting, the idea that such a massive liability might be created at any future date would certainly chill the most courageous underwriter. This type of sudden liability expansion is more likely to deter the growth of insurance markets than it is to provide a financially sound system of injury compensation; it would therefore defeat its own objectives.

The Study Group majority itself was aware of the problem that an overtly retroactive liability scheme would present; it attempted to circumvent retroactivity to some extent. While its recommended scheme would allow a number of retroactive claims by claimants* against the

---

* Claims could be filed within three years of discovery, whether discovery occurred before or after passage of the implementing legislation. (Report at 209). Further, since discovery of injury might take place many years after the initial exposure to

(Footnote continued)

administrative agency (Report at 209-10), it would permit subrogated claims against industry members only for injuries or damages caused by exposure to "wastes disposed of, transported or spilled after the adoption of this proposal. . . ." (Report at 246). However, this is not an effective remedy to the problem of retroactive liability. Industry would end up footing the bill retroactively anyway because, under the Study Group majority's recommendations, unsubrogated claims would be paid through a tax on industry. In all fairness, if society decides to pay such retroactive costs, society in general should foot the bill, rather than attempting to load it unfairly on a small segment of its members.

Further, as we have seen, "toxic torts" may often involve diseases that take as long as 20 or 30 years to develop; claimants may have been exposed to a combination of substances deposited by a number of different companies both before and after implementing legislation is passed. It might be virtually impossible to sort out injury resulting from substances deposited both

---

(Footnote * continued from previous page)
toxic waste, many claims -- and certainly the most catastrophic ones -- would in effect be "retroactive."

before and after the cut-off date, or from substances deposited by different companies. Subrogation suits would thus become an expensive nightmare of claims and cross-claims.* Alternatively, legislative proposals such as the Minnesota Act have permitted suits retroactively unless there is proof that "the substance was placed . . . in or on the facility wholly before" a cutoff date -- in Minnesota the date is set at January 1, 1980.** But for activities that continued after the cutoff date, the Minnesota Act provides extensive retroactive liability as a practical matter, and also fails to solve the problem of cross-claims, thus creating the worst possible "solution."

6. Add-On Remedies

> "[F]ree access to the plenary tort action after the claimant had already had a compensation award on Tier One would be prohibitively expensive from the insurance point of view. A system which called for a binding election between the tort remedy and the compensation remedy

---

* The continued or increased use of joint and several liability of defendants in Tier Two lawsuits would also presumably result in a tangle of cross-claims for contribution in the courts.

** Minn. Stat. § 115B.06(1)(b). The Minnesota Act also provides an additional defense if the substance was deposited prior to January 1, 1973 and defendant's activity was not an "abnormally dangerous" one. Minn. Stat. § 115B.06.

> would be more readily insurable." (View Expressed to the Study Group, Report at 174).

Administrative remedies, in order to be practical, have traditionally involved a trade-off: relaxed standards of proof and easier awards must be balanced by a limitation on the amount recovered. Despite its claims that Tier One is modelled on workers' compensation (Report at 195), the traditional quid pro quo associated with such a compensation system has not been adopted by the Study Group majority's recommendation. Instead, the Study Group majority:

> "adopted the worst of both worlds: an administrative compensation system with liberal evidentiary standards and generous benefits, as well as continued availability of traditional tort law." Office of Management and Budget, Compensation for Toxic Substances Exposure 13 (May 19, 1983).

By providing an administrative recovery with reduced evidentiary burdens for plaintiffs, while doing nothing to provide either a bar or a binding election against further tort claims in court, the Report has gone far beyond the workers' compensation model it claims to follow. Since plaintiffs will typically be seeking large "pain and suffering" awards, which they would not receive in Tier One, the incentive to "go for it" in court would be high. A plaintiff could use his Tier One administrative recovery to fund a subsequent lawsuit in court, thus (in effect) causing the likely defendants to pay the cost of suits against themselves.

The Study Group majority's sole attempt to limit the use of both Tiers by plaintiffs was to permit (but not require) a judge to impose court and expert witness costs on the plaintiff if the plaintiff fails to recover at least 25% more in court than he did in the Tier One administrative proceeding.*

> "Such an assessment, to be made at the discretion of the judge in the plenary court proceeding, is to take into account whether the plaintiff's action was brought in good faith, with a view of avoiding frivolous and duplicatory proceedings." (Report at 202).

In reality, it is doubtful that such costs would be assessed with any frequency. Plaintiffs will usually be individuals of limited means suing defendants who are large corporations; as a practical matter, it would be a rare case in which a judge would find plaintiff's pleading sufficiently frivolous to warrant the imposition of a cost sanction.

---

* A Joint Statement of dissenting Study Group members proposed that once an administrative award was given, claimant should be required to submit to a hearing in court to determine if a lawsuit is warranted, before being allowed to proceed with the lawsuit itself. (Report at 286). Even that system, however, involving yet another hearing, would proliferate legal proceedings and transaction costs. In this regard, consider the view expressed by Study Group Member Jeffrey O'Connell (Report at 354-55) that the three-proceeding structure proposed by the Study Group (i.e., administrative claim, subrogated claim, claimant's lawsuit) was excessive. Mr. O'Connell nonetheless joined in the Joint Statement.

With much to gain and virtually nothing to lose, it is unlikely that many plaintiffs would be deterred from going forward in both Tiers. Thus the Study Group majority's proposal would simply increase the administrative costs of the system overall by adding the Tier One proceedings and administrative costs to the present proceedings and costs of court litigation continued in Tier Two. Such an expensive, cumbersome system lacks any logical support.

V. CONCLUSION

The recommendations of the Study Group majority, and the legislative proposals based on those recommendations, are both unfair and unwise. It makes little sense to rush into such a radical "solution," involving so many pitfalls and draw-backs, as well as staggering costs well in excess of the harm caused. Instead, concerted effort should be devoted to the prevention of such problems in the future, by rigorous enforcement of existing laws, such as the Clean Air Act, Clear Water Act, and RCRA, and by retention of the incentives for proper conduct inherent in the tort system.

In addition, funding should be increased for professionally-conducted studies to determine in a rigorous way what causal links exist between exposure to hazardous substances and the harms claimed to result from such exposure. Once science has established what causal connections exist, there will be little need for Congress or state legislatures artificially to ordain such connections by legislative fiat, or to require compensatory payments from those who are not at fault and not the responsible parties. The American Insurance Association suggests that dispassionate scientific inquiry, coupled with traditional tort law principles assigning liability to those at fault who caused the harm, is the best and most rational means of achieving a just, economic, insurable and workable compensation system for injuries caused by hazardous waste.

TECHNICAL APPENDIX A

Estimation of Average Claim Costs for Workers' Compensation Cancer Cases

The National Council on Compensation Insurance (NCCI) has estimated the current average cost of a worker's compensation cancer claim to be $130,000 based on data for claims which have already been filed, as explained below.

Worker Benefits

A review of reported workers' compensation cancer cases showed that the typical claimant was a fifty year old male who lived for three years after he became disabled and incurred medical expenses approximately equal to his wage loss benefits during that period. The costs of these claims were calculated using current wage rates so that no adjustment for inflation was made.

Survivor Benefits

Existing rules allow for the worker's widow to continue receiving benefits after his death for a duration of up to ten years unless she dies or remarries prior to that time, whereupon benefits cease. Widow's benefits were limited according to these rules using standard mortality tables and the results of an NCCI remarriage study which provided distributions, by age, of the number of women expected to die or remarry in each subsequent year.

Mr. **Levitas**. Ms. Birnbaum, first let me say without objection we would like to receive from you the listing of the types of cases or settlements that you are aware of. That would help us.

Ms. **Birnbaum**. Yes, sir.

Mr. **Levitas**. We heard the other day from at least one witness, who said we ought not to create a system of victims' compensation because there isn't enough scientific evidence to prove the case that people are injured by hazardous waste sites. You make the argument we ought not to establish a toxic tort system, statutory victims' compensation system because the tort system itself, the common law system, has not yet had a chance to prove itself to work.

My question to you would be—because you are approaching it from a different angle than Dr. Karrh did the other day—is that where we see a system, or a circumstance that has evolved in a relatively short period of time in terms of public awareness, and in this case the hazardous waste sites and the relationship to personal illness and ailments resulting therefrom, why should we wait 5 years to create a system that will address the issue, because one of the necessary hypotheses of the common law approach is that it has to be based upon precedent and unless the first case decided establishes a precedent from that time forward then you have literally hundreds or thousands of individuals who are not getting treated the way that they would at the end of the line.

Yesterday I mentioned the case of *Buick* v. *McPherson*. How many people went uncompensated before 1933 or whenever it was because they couldn't prove privity? That may be fine, but if we have the opportunity to let those people go uncompensated, shouldn't we avail ourselves of that?

At that point, I am going to give you plenty of time to think about your answer because those are the second bells of a live quorum which is taking place on the floor and we are also going to be asked to leave this room because they need it for another meeting at a later time this afternoon.

So what I am going to suggest—I said there would be a luncheon break—we will recess now until 20 minutes until 2 and reconvene in room 2253 on the second floor of this building and we will start off with your answer to that last question.

Ms. **Birnbaum**. Thank you for the opportunity to reflect on it.

Mr. **Levitas**. Thank you.

[Whereupon, at 12:35 p.m., the subcommittee was recessed, to reconvene at 1:40 p.m., in room 2253, on the same day.]

Mr. **Levitas**. The subcommittee will please come to order.

While Mr. Cheek has not yet returned, I think, Ms. Birnbaum, you have the floor in any event.

Ms. **Birnbaum**. Would you like to restate the question, Mr. Congressman?

Mr. **Levitas**. No.

Ms. **Birnbaum**. Well, I think the gist of the question was, if we wait for the common law system, maybe some people will not be compensated while the common law system is developing. The response to that is that the common law system is already in place. It is not in a developing stage with repect to doctrines and standards of liability. They are in existence now. Over the last 10 years, especially as a result of the asbestos litigation, a whole body of law has been developed which is being applied in all types of toxic substance cases.

I think that, when I was talking about waiting and seeing, I meant that we should wait and see whether the common law will keep expanding to meet new situations, which in the past it has done. The precedents are in place. The concept of strict liability, whether through product liability law or through the restatement of torts principles applicable to abnormally dangerous activities, is in place. I believe there is no need to wait for precedents. There are some questions in the relatively new context of hazardous waste litigation that might remain unanswered in a particular lawsuit but the courts are dealing with these, and that has always been the process of the tort system and common law development.

I think it would be something of a mistake not to allow the courts in the first instance to try to handle these problems as well.

Mr. Levitas. Let me ask you this. Based on your experience as an attorney in toxic tort cases, you made reference in answer to Mr. Molinari's question of the situations in which claimants or plaintiffs have recovered. You are going to furnish us additional information.

Let me turn that around. Tell us about the cases in which the claimants have failed or been denied compensation, and why.

Ms. Birnbaum. I think we can look at the asbestos cases, which is a category of toxic torts in which there has been much litigation. In many of the cases where the plaintiff does not recover, it is because of the insufficiency of the evidence as the issue of causation. In other words, the plaintiff has failed to establish to the satisfaction of the jury either that he has the illness he is alleging he has, or that he has been exposed to the particular toxic substance alleged to have caused his injury.

So in most instances, after a jury trial in the asbestos cases, which I think we can use as some sample of what has been happening. The plaintiff who does not recover has failed to establish causation: that is, failure to establish that in fact there is an injury that is associated with any degree of reasonable medical certainty with the particular toxic substance involved, or that the plaintiff does not have the injury that is allegedly associated, on a statistical basis, with the toxic substance. And it is in those two areas—general and individual causation that I think, if we reviewed the cases, we would find that most of the plaintiffs have failed.

Mr. Levitas. We have heard a lot of testimony over the last several weeks by persons who are advocating changes in the tort system that suggest a shifting burden of proof, or a shifting requirement to go forward with evidence, or a presumption under certain circumstances. This morning we heard Ms. Hall suggest three criteria for threshold of shifting, of either going forward or burden of proof, or as a requirement to raise the presumption.

I think the first was a showing of exposure that is reasonably related to the chemical or toxic substances involved. A scientific link between the chemical and the injury or ailment that the person complains of. And finally, the injury itself. Those were her three criteria.

Would you address yourself to the question of shifting burdens, presumptions, thresholds, and so forth?

Ms. **Birnbaum**. Thank you for the opportunity to do that. I think that if a plaintiff proves those three elements, the plaintiff doesn't need the burden to shift. The plaintiff has met the burden of proof at least as it is spelled out in most courts today. So there is no need to shift the burden. In fact, as a practical matter, the burden shifts to a defendant in a courtroom in any event if the plaintiff is able to establish the elements you describe.

Now, I think what you might have been suggesting is that the burden of all of those elements should be lessened so that the plaintiff could meet the burden and then a presumption would arise. That is, the plaintiff would have met his or her burden by establishing exposure over a sufficiently long period of time to have gotten the illness; a scientific link, that is, an expert is going to be able to testify with some degree of medical certainty that this injury may be caused by exposure to this substance and that the person is injured.

That is not very different from what is happening in most courtrooms today. That is what the plaintiff has to in effect prove by a fair preponderance of the evidence. In my opinion in most of the cases I have seen, the plaintiff has, in cases have established causation or in cases where causation can be statistically shown, or there is a statistical association, the plaintiff has not had a great burden at least after the initial cases were brought, in establishing that a product or exposure to a substance has caused the plaintiff's injury.

I think what we are hearing a lot about now are the newer cases where in the first instance the proofs are uncertain. Even in these cases, however, juries do what their job is—that is they sort out the facts and try to come down with a reasoned determination after listening to the experts. We are dealing in areas where there is not a great deal of established scientific fact. This raises the whole issue, I think, of whether there should be presumptions in the first place as to causation. It seems to me that the tort system, where one group of experts attempt to spell out the plaintiff's theory, and another group spell out the defense theory, and then the jury or trier of fact attempts to sort all this evidence out, makes more sense than a presumption.

She is suggesting really is what in reality in most instances we have in the courtroom today. The plaintiff has the burden. Once the plaintiff meets that burden, then the plaintiff goes to the jury. If the defendant does not rebut it, even though the jury may not be told this is a presumption in real life, that is what occurs.

Mr. **Levitas**. What about the other point Ms. Hall made about the fact that a great deal of the evidence in cases of this sort are of a statistical or epidemiological nature? What is your view about dealing with the questions of admissibility of that type of evidence?

Ms. **Birnbaum**. I don't have the statistics on it, but what we are seeing more and more is that courts are permitting that type of evidence in, I think as you pointed out, through expert opinion. The expert gives an opinion based on all that the expert has read or experienced. Part of that opinion could be based on epidemiological studies, animal tests, pathological tests. All of these are things that the expert, when he testifies, depends upon in supporting his opinion.

Now, the problem in some cases is that some of this evidence is so speculative that it may be stricken, or not be given a great deal of weight. But then again, perhaps it shouldn't be given alot of weight because of its highly speculative nature.

In Federal courts and many State courts, medical articles and other scientifice articles that the expert relies on are admitted into evidence for the truth of what they say. In the asbestos cases, for example, all of this data gets put in evidence through the plaintiff's experts. In the future courts will have more and more of that kind of evidence put before them, and are going to deal with that because this is the way cases get proved.

Mr. LEVITAS. I believe that is the point I was getting to, using the expert.

Mr. Cheek.

Mr. CHEEK. I apologize, Mr. Chairman, for being late. It is very hard to get lunch outside of the building.

Mr. LEVITAS. Do you want to hear my sad story?

Mr. CHEEK. The two questions you raise are very closely interrelated. Many of the bills that have been introduced so far would allow virtually any kind of statistical evidence to be put into the record and would give that evidence the status of a presumption in favor of the claimant.

The problem really lies in giving what Professor Birnbaum calls highly speculative evidence the status of a presumption. I think it would be useful to get on the record some discussion of the problems that statistical evidence presents.

First of all, in the context of long latency diseases, it is just not medically possible, except in a handful of cancers, to assign a single cause to any of those diseases. And proof of causation in such cases, therefore, becomes necessarily a statistical exercise as to which of the multitude of possible causes is the most probable among the causes.

That brings to mind the old adage that "statistics don't lie, but liars use statistics." As you have seen in other contexts, I am sure, statistics can be extremely misleading. But in most other contexts, absent a presumption, as Sheila points out, the misleading effects of statistics can be offset by either expert testimony on the other side or empirical proof. But that is really not possible in these hazardous substances injury claims. If you load up the statistical proof with presumptive weight, it becomes almost impossible to create any kind of rebuttal to that.

Abuses are possible in each of the three major categories of tests commonly used to establish associations between certain substances and the onset of certain diseases—epidemiological studies, animal bioassays, and bacteria and mammalian cells in tissue culture.

First, epidemiology. Although every human carcinogen we know of has been identified by means of epidemiology, it is very expensive. Epidemiology's expense and relative statistical insensitivity are complicated by cancer's long latency, which requires the studied population to review decades of personal habits and occupational and medicinal exposures, and to estimate the dose levels of suspected causative agents.

Epidemiology is further complicated by multiple exposures and possible interaction between suspected agents like smoking and asbestos, for example.

Finally, epidemiology is helpless to deal with the countless new chemicals which are put on the market each year, to which very few humans have been exposed. But the fact remains that epidemiology is the only tool that we have that can directly identify human risk factors and the only tool that does not have fundamental problems of interpretation.

Turning now to the second major tool, animal bioassays, they are subject first to the criticism that they are really just surrogates for human experience and therefore can't tell us with any certainty that a given substance even can cause human cancers, much less that it in fact does cause human cancer.

More importantly, animal bioassays are subject to dosage abuse so severe that it is possible, for example, to establish that such common substances as sugar, pepper, eggs and vitamin D can cause cancer in animals. In fact, there are now instances in the scientific literature where epidemiology has been unable to confirm a cancer risk suggested by rodent tests. Examples include saccharin, hair dyes and DDT.

Given the potential for abuse in such tests we would think that if you were looking at the use of such evidence in a victim compensation measure, you would want to be very sure to prescribe the protocols that would have to be met in any animal test submitted in support of a claim that a hazardous substance caused the claimant's disease.

Third, and finally, bacteria and mammalian cells in tissue culture. These, too, are proxies for human experience. They are used to examine capacity of the test substance to induce mutations or other genetic damage. While the results of the tests do correlate highly with those in animal bioassays, the Okey-Ames test, as it is called, misses certain chemicals, like dioxin, for example, that are proven carcinogens in animal tests and humans. Thus they have inherent limitations that should be identified and safeguarded against in any victim compensation legislation.

If you don't have controls on the kind of evidence a claimant is able to bring into a system, the Congress would be inviting what I call "junk science" in support of claims for compensation. We have already seen, for example, in the first so-called study of chromosome damage at Love Canal the dangers of junk science. If you don't have, for example, a control group in an epidemiological study, it is essentially worthless.

Finally, there are ways, I think, to assure that the best science is available to both toxic substance claimants and defendants. There is underway, of course, the new Toxic Substances and Disease Registry, but we think that the Congress might want to consider going further than that, by combining the capacities of that new organization and all the other existing Federal agencies that are looking at aspects of disease causation: the National Science Foundation, National Academy of Sciences, NIOSH, etc.

If all of that expertise could be brought together in a single entity, a great many of the problems that are leading to pressures for presumptions could be solved by making sure that there was a source of reliable and good scientific evidence to back up or rebut claims of hazardous substance disease causation.

I am sorry for the length of that answer but I thought it was something that should be covered thoroughly.

Mr. **Levitas**. I want to get back to your answer in a minute. I think I will save it for my next go round. But I do want to get back to that because you come perilously close to another concern that I think we have. But I will save that.

You, in your testimony, Mr. Cheek, put out a proposition that at the time struck me as being fascinating. I had never heard it put that way before. Not being an expert in this field, I can't say that it is novel, but it struck me. You were making the point that in the use of statistical evidence to ascertain the causal effect between a toxic substance or hazardous waste site and individual ailments, that one of the methods that is used and that certainly has persuasion to the layman such as myself is that in a particular community where you have an unusual incidence of a particular disease, and that particular disease has scientific linkage with particular toxics, that that is utilized as a basis for the cause and effect requirement.

Then you went on to say that whatever the statistics, the numbers were, but the numbers you used was what, liver cancers as I recall, a hundred——

Mr. **Cheek**. Normally expected.

Mr. **Levitas**. Would be the normal. There is two percentages which you used, but let us say 5 percent incidence, which places it in the abnormal category. Then you make the point, which I thought was very interesting, you say you thereby create a situation of over-inclusivity, because not only are the additional five people or two people the ones who presumably——

Mr. **Cheek**. Could have.

Mr. **Levitas** [continuing]. Have had this ailment because of the toxic substance, but how do you know which of the two—of the 105 or 102 it is. Thereby everybody in that community would be a potential claimant. When I first heard that it sort of struck me that, gee, that is very, very interesting. And it creates a problem, because the other hundred would have developed the cancer under any circumstances, or without this hazardous waste site, or the toxic chemical relationship.

And now they would qualify theoretically at least as potential claimants. On the other hand, as I began to think about it, it occurred to me that there are some at least possible mitigating pieces of evidence that work against that. You take the situation in Congressman Molinari's district, where they ran a number of tests in a particular community. And they used the Staten Island area really as a control for this, what is it, Brookfield?

Mr. **Molinari**. Brookfield.

Mr. **Levitas**. The Brookfield community is close to the dump where hazardous wastes were illegally disposed. In the Brookfield community they found an unusual number of these particular types of ailments, far in excess of what you would find elsewhere in the Staten Island area. I remember in the decision that EPA made on, I forget the numbers, but it was the herbicide that they sprayed out in Oregon, if I recall correctly. And there were a number of abortions, miscarriages, that were not tremendous in terms of the number over what was occurring, but it was abnormal as compared to the rest of the population where this particular substance was not sprayed.

Now, having laid out the dilemma, surely a layman such as myself would conclude based on Mr. Molinari's statistics or the statistics in an Oregon or the Mirex statistics in Mississippi and some other places, that there is a cause and effect relationship. And since we are able to place the people in Brookfield close to the toxic site, and those further away not close to the toxic sites, doesn't that provide a cutoff?

Mr. CHEEK. It does in many instances. The only place you would have a problem is where you have something that is common to the whole area. Clearly, if you are talking about people in proximity to a dump site, yes, that would seem to be almost a self-sealing off kind of population that would admittedly be eligible to bring either a tort claim or some kind of administrative claim.

It would seem to me that where there is so clear a relationship between the exposure and the health effects that those people are suffering, a normal tort action would not only lie, but would almost certainly succeed given, what is it, a 50 percent higher incidence among the people around the dump than elsewhere on Staten Island? That is an extraordinary——

Mr. MOLINARI. One hundred percent.

Mr. CHEEK. That almost by itself exceeds the normal tort threshold of 51 percent in effect of proof. It would seem to me that there is a clear instance where, if the people in that community brought a class action, they would be certified as a class and presumably have very little difficulty in establishing that there is tort liability on the part of the defendants involved in placing that or those hazardous substances in that dump.

There I think is a clear instance where you would not need either the benefit of a presumption, or what I would call junk science, to substantiate the claim.

Mr. MOLINARI. Suppose there were only three people—would the Chairman yield?

Mr. LEVITAS. Yes.

Mr. MOLINARI. Suppose there were three people living in the area, all three suffering from the same symptoms. You don't have 1,000, 1,500.

Mr. CHEEK. There, too, I would think, if there were a common association in their view as to the cause of that illness, and no similar illness elsewhere in the community, there, too, there would be no need for any presumption that the disease was related to the exposure.

Mr. LEVITAS. Well, I happen to agree with that conclusion, that judgment. On the other hand, it still poses the problem to me intellectually that there would obviously be some people who would be certified as being appropriately part of that plaintiffs' class who developed the particular ailment, but developed it quite apart from their proximity to the toxic waste site. I don't think there is anything you can do about it. It is either a question of compensating some people who were not in fact injured by that toxic waste site, or not compensating those who were.

If you are going to err, you have to err, it seems to me, on the side of compensating victims, and, you know, the old theory of some of the guilty go free. Or innocents get convicted, whatever.

Anyway, Mr. Molinari, I will come back to that other line after you have had an opportunity.

Ms. **BIRNBAUM**. Could I speak to that?

Mr. **LEVITAS**. Yes. I thought you would.

Ms. **BIRNBAUM**. In part to that.

Mr. **LEVITAS**. Yes.

Ms. **BIRNBAUM**. I think the answer to that is that the over-inclusive nature also has an impact on the costs. If, say, just using those statistics, we are talking about 100 people that are going to be able to recover, maybe only two of them have been injured by exposure to a hazardous substance; the other 98 may have developed disease from extremely unrelated sources.

We have 400,000 cancer deaths in this country a year, 880,000 people were diagnosed with cancer last year. Statistically there are all kinds of numbers that people throw out of what may or may not be caused by toxic substances in the environment or the work place. The latest studies, the Dahl study which I make reference to in my paper, seems to indicate that less than 2 percent of cancers, 2 to 5 at most, come from chemicals and pollutants in all areas of the environment: air, water, food.

So what we are talking about here is compensating anybody who not only might live near a hazardous waste site, but even those people who just passthrough the area or work there for several hours. I mean it is very hard to draw the kinds of lines in an administrative proceeding that you are talking about. And the costs I think would really be prohibitive under that kind of system. But that is only a partial answer I think.

Mr. **LEVITAS**. Thank you.

Mr. Molinari.

Mr. **MOLINARI**. I don't know where to start. I am trying to recall the source. But there was a source—it might have been the Chemical Manufactures Association paper—which indicated that people who work in chemical companies, with all of the protective equipment, would be exposed to a risk greater than that of the public on the outside because of some opportunities for exposure when there shouldn't be exposure.

Yet it was interesting to note in their final statistical analysis that the chemical workers have a lower incidence of cancer than the general populace. Of course they want you to believe if you want to avoid cancers you should work in a chemical company.

Ms. **BIRNBAUM**. Chemicals are good for you.

Mr. **MOLINARI**. There is no doubt that they have done a lot of good. I can understand, Mr. Cheek, your statements indicating the difficulties with the predictability of loss and how that poses a problem in determining rates that you would charge to one of your insureds. But take a person in my area who would die, let's say, from lung cancer, which is one disease for which we do have a very high rate.

If the person lived in the Brookfield area, and was to sue the party responsible for the chemicals, the chances are that he would be hit with the comment that his cancer could be caused by smoking or some other problems, for example, coal burning power plants. But if we go to the Tobacco Institute we would hear, as I heard here as recently as a week ago, a vigorous denial of the assertion that smoking will cause lung cancer.

Then we go to the remaining source, and that is the smokestack emissions coming from coal burning sources. And I listen to the coal industry and they say it is a lot of ballyhoo. They don't to this day admit, for example, that there is any causal relationship between coal burning power plants and acid rain, though the evidence is starting to come in to the contrary.

Brookfield is not an isolated case. I listened to your assessment as to the legal position of the residents of Brookfield. I couldn't help but think that if we wanted to, on this subcommittee, put on a parade of witnesses victims who have had the same health problems as the people near Brookfield, we could have hearings every day of the week, go forever, and never catch up. I am sure we would hear the same story time and time and time again. As a matter of fact, we have had witnesses before us that told us the same thing.

Now we have also heard from lawyers whose views somewhat sustain your position. Mr. Baron, in particular, was one who said that given a set of facts lawyers generally can prove a case.

But the overall picture, looking at the masses, is one in which we are not necessarily looking at those who have been in severe straits, debilitated. What I am hearing from the trial lawyers about toxic tort litigation is that given the serious case, they will take their chances. But I don't think the average case is that serious. I put quotes around "that serious" because I don't think anybody knows what really "serious" is because of latency periods in particular. But we do know that lawyers have a way of evaluating a case when it comes into their office in order to determine whether they are going to take it on on a contingent fee basis and invest the amount of time and resources that they have to, in order to, hopefully, come out ahead at the end.

But the average case is not a cancer victim. Maybe the case will involve special damages that might amount to several hundreds of dollars. The victim is still faced with the difficulty that we have heard time and time again of getting medical experts. In fact, we heard the rates they were charging were $350 an hour for their time. So how can we say that the system is in place for these people? When I think in terms of Brookfield we may be talking about 1,000 people. But again I don't want to isolate on Brookfield because I don't view Brookfield as a unique case.

I think that there are thousands of Brookfields throughout the country. In fact, there are over 1,000 sites under investigation in New York State alone. So I really see out there the possibility of many hundreds and hundreds of thousand of people who have injuries that are caused by exposure to nearby dump sites and toxic chemicals at the sites. But they don't have sufficient amounts to warrant a lawyer's time.

In my community, as I have said to the chairman, we have maybe 600 or 700 lawyers. If any one individual of those Brookfield residents went to a lawyer, I suspect he wouldn't get 15 minutes of the attorneys time. The lawyer would dismiss them and say to his partner, "Thank God I got rid of that one. That is another loser." You know, lawyers can go broke taking cases like that.

Now, if toxic tort litigation is such a lucrative practice, and if the system is in place and the technology emerging as is claimed, why is it we only have Mr. Baron's firm, which is eight lawyers and, I think he mentioned, only one other firm in the country, which has two lawyers, handling toxic tort litigation. I have difficulty reconciling the assertion with the reality.

Ms. **Birnbaum**. Let me just say, my own experience is that there are many, many, many lawyers practicing in this area of the country. Mr. Baron may be one of the most outstanding ones and one of the better known ones. But if you look around at what has happened in the asbestos litigation, all of those lawyers are trained, competent people. Not all.

Mr. **Molinari**. I would like to stay away from asbestos.

Ms. **Birnbaum**. But that is where you find the cadre of lawyers that are going into this whole new area. That is how Mr. Baron, among others, started out learning the toxic tort area.

Mr. **Molinari**. Sure, but it is a lot easier because you are dealing with cases where you have a known source—asbestos.

Ms. **Birnbaum**. Yes, but you have——

Mr. **Molinari**. You have an isolated source that you are dealing with. Ninety percent of your problem is solved before you start. If you are living near a dump, you may have hundreds or thousands of chemical compounds. You don't know what you are facing when you don't even know what the compound is. How much does it cost to prepare a plaintiff's case in a toxic tort litigation case? What would be a minimum sum required?

Ms. **Birnbaum**. I think it is impossible to give you an estimate without knowing the dump site: what has been put into the dump site: what are the relationships statistically and in the medical literature between those particular substances and what is being alleged. And what I think happens, and I would be surprised if it wasn't happening in your area as well, is that if there are people who are injured, a lawyer doesn't handle just one case. What happens is a lawyer begins to handle hundreds of cases involving people in that neighborhood, sometimes consolidating the actions and bring them together.

So it isn't a question of handling one case, either through joinder or through class actions, what happens is lawyers go out there and sign up. "victims." And if there are real injuries it seems to me there is no shortage of lawyers in this country to handle the cases.

Mr. **Molinari**. Let us go to the next step then and I will tell you what happened.

Ms. **Birnbaum**. OK. I would be curious to hear. It sounds like you may need a lawyer.

Mr. **Molinari**. Some Staten Island residents living near Brookfield went to the attorney who handled the Love Canal case. From the information I have received, he came in and apparently made some type of evaluation. He reportedly wanted a certain flat fee from each one, I suppose to cover the initial work that they would have to do. There was a great reluctance on the part of a rather substantial percentage of the people to put up that money.

These people have had so much difficulty for 19 months trying to get any of the health agencies to tell them what is there and what remedial action can be taken, that they are just totally puzzled. In fact, what some of them have done, frankly, is to sell their homes and get out of there.

So that when I hear that the present system is adequate and then try to equate that with what I know is happening back home, it doesn't square with the experiences that I have seen.

Mr. CHEEK. Mr. Molinari.

Mr. MOLINARI. Yes?

Mr. CHEEK. I think Fred Baron referred yesterday to several lawyers that he knows in New York who would be more than happy to hear about the Brookfield case. As I recollect, he was willing to supply you with their names. I think he even mentioned a couple during his testimony.

Mr. MOLINARI. I made note of that, as a matter of fact. However, as a Congressman, I would not as a matter of practice recommend an attorney. If somebody calls my office, I would likely refer them to the Bar Association.

Mr. CHEEK. I think New York City is certainly one of the centers in which toxic tort law is developing at its most rapid pace.

Mr. MOLINARI. We talked the other day about a 6-year-old child, not from Brookfield but from another area of Staten Island, who is dying from a condition which it is thought might be the result of exposure to toxic chemicals. One of our attorney witnesses said he would take the case of the 6-year-old child. But he was speaking off the cuff, and probably assuming everything else was in place.

I also think he was influenced by the young age of the victim, as opposed to an older individual whose life expectancy would have some impact upon the measure of damages. But I still see this very serious question of trying to prove causal relationship. I don't truly believe that the state of the art is such today that, with the tests that we have, you can indeed prove that.

I took a population health survey. The city did one, also. We came up with amazingly similar results which told us there was a problem in the area. That was enough for us to be satisfied that further action had to be taken by the health department. Whether there was enough evidence to enable these people to go into a court of law, to seek redress and collect damages, I wouldn't want to speculate.

But I would suspect they had a lot further to go.

Ms. BIRNBAUM. I think that is probably true. But isn't it a concern of where you draw lines?

Mr. MOLINARI. Yes.

Ms. BIRNBAUM. Let us say there is someone in your area near that dump site, and that person has headaches. Now, is that person living a half a mile from the dump site, 1 mile from the dump site, 2 miles from the dump site? What about the person who has headaches and lives 3 miles from the dump site? Once you start on this route, the question of whether the headache is related to the dump site becomes extremely difficult to resolve.

The question of where to draw lines is a very hard one. I think even around Times Beach, what occurred at first was the Government was willing to buy the houses of residents that were *x* feet or miles from the dump site. And very soon after that, there was a question of should they buy the houses that were the next *x* miles, and then the next *x* miles until the Government might have to pay for all the houses in Missouri.

That is an enormous problem with the way all these bills have been put forth, even assuming there is causal——

Mr. **Molinari**. Have you read much about Times Beach?

Ms. **Birnbaum**. Just from what I have read.

Mr. **Molinari**. Would you hesitate to live there?

Ms. **Birnbaum**. I live in New York City. That is polluted enough. I am not sure if someone asked me that question where I would live. I don't think I would move to anywhere in Missouri, but that is lifestyle. But I don't think I would move to Times Beach, either.

Mr. **Molinari**. Would you move to Staten Island?

Ms. **Birnbaum**. I sometimes visit.

Mr. **Molinari**. You don't stay too long. How about you, Mr. Cheek, would you live there?

Mr. **Cheek**. Would I live in Times Beach? I don't think I would want to, sir.

Mr. **Molinari**. I appreciate that candor. The chemical manufacturers' representative said he would have no hesitancy to do that. I asked, "How long would you stay?" He said he would have no problems staying there 4 or 5 years. I think it was the following day that NIOSH came out with the report indicating that indeed there might be some causal relationship between dioxin exposure and cancer.

Mr. **Cheek**. Mr. Molinari, could I ask you a question about the people around that dump?

Mr. **Molinari**. Yes.

Mr. **Cheek**. Is there concern that they are not being made whole for the medical expenses and lost wages that they are now incurring?

Mr. **Molinari**. No, not really. Their concern is a health concern.

Ms. **Birnbaum**. Of the future?

Mr. **Molinari**. Present and future. Those people have health problems now, themselves and their families. There are some interesting phenomena. We had a witness from the area last week testify that when the family goes away for a vacation for a limited period of time, a lot of the symptoms disappear. Hours after they come back to the home the symptoms reappear.

Mr. **Cheek**. My sense of what your concern is is not that they are not being compensated for the out-of-pocket expenses associated with those health effects, but rather the perception that they don't have the front money to, in effect, bring a lawsuit for other than economic loss associated with those health effects.

Mr. **Molinari**. Let me lay it out for you. My primary concern is for the unknown health effect. I do know that they have health problems. How serious they are, I don't know. I get asked for example, "Congressman, should I move?" How do you answer the question? What a terrible question to be asked. What a terrible position to be in, trying to answer it.

If you say yes, you will probably instill a sense of panic in the neighborhood. If you say no, then you have your own conscience to answer to if they stay there and they do have a problem.

I know of another area where toxic dumping has been alleged to have occurred. It has not been publicly divulged. I have been attempting to prove that that is the case before I release any information so I don't send panic through the neighborhood. We've been a year working on that and have not really made any progress. Organized crime is involved, compounding the difficulty in getting information, and I rest very uneasy on that.

But now let's go from there. If, in fact, the people there have legitimate health problems caused by the existence of toxic chemical substances, then, yes, indeed, they should be compensated. I assume the amount of their recovery should be like any other negligence case, depending upon the nature of their injuries, permanency of their injuries, their special damages.

As I said before, Brookfield is not an isolated case; I am totally convinced that there are thousands of Brookfields in this country. And I have, myself, done some more limited inquiries into sites throughout the country. I appeared on C-Span here in Washington for an hour. For the first half hour we talked about this problem. Then the second half hour I took phone calls, which came in from all over the country, from people alleging the same kinds of things and asking me for help.

As is true for any of my colleagues, I have enough problems trying to do my job here and answer to the people of my own district. People out in Starrett City called me and asked me to go out there and help them. They are terrified. I would love to do it, but I don't have the time and I don't know how much help I can be. My point is this: we do have a toxic waste victim problem in this country. I think the primary concern for all of us is to try to assess how serious it is so we can try to assist those in need of some kind of help. Then, if there is a guilty party, just like in any other area of the law, that guilty party should compensate the innocent person that has been injured as a result of the guilty party's practices.

Ms. BIRNBAUM. You just used the word that is the heart of what I think I have been saying. If there is a guilty party. If there is a party who was at fault. Many of the suggestions are to hold companies liable who may not have been guilty parties at all, who may have just had the circumstance of dumping properly in the same dumpsite as——

Mr. MOLINARI. The joint and several liability aspect. I understand. That is a very valid point. You mentioned that point before and I made a note of it because I think it is very legitimate. I have other questions, but I think I am going to have to cut them short because one of our other witnesses has a time limitation. But I appreciate your help.

This may be difficult for you to answer, but how about punitive damages? Do you believe there is a place for punitive damages in this area? One of the witnesses used the term "outrageous conduct," stating he felt that punitive damages might appropriately be improved in such a situation.

Ms. BIRNBAUM. Speaking for myself, and I can speak only for my own personal feeling about punitive damages in this context, I think there is a place for punitive damages where there has been outrageous conduct that is in disregard of human safety. When companies try to cover up information, knowledge that they have, to the detriment of people's safety, then the common law response is to hold them liable for punitive damages. I think the problem may be that in some instances we are using punitive damages in the products liability area too expansively, taking in other than outrageous conduct.

But the deterrent effect of punitive damages is a very valuable one in common law, and there is a place for it, so long as there are correct guidelines and standards.

Mr. **Molinari**. Is that insurable?

Ms. **Birnbaum**. It depends on the State you are in.

Mr. **Cheek**. New York, for example, I think prohibits insurance of punitive damages as being contrary to public policy.

Mr. **Molinari**. Public policy.

Mr. **Cheek**. We, and I think most other companies, routinely exclude the coverage of civil fines and punitive damages from normal general liability contracts.

Mr. **Molinari**. I find the testimony intriguing and I thank you both. I am sorry we have to cut it short.

Mr. **Levitas**. There is one question that I want to ask you, Mr. Cheek, because I don't want to let you leave without shedding some light on the record for this.

I have wondered ever since this whole question began to arise several years ago, how in the world do insurance companies arrive at their premium costs in an area that there is really no statistical data on in terms of historic liability. Normally you set your rates on what you have had to pay off in the past. Now, this is a new field. You don't have this historical basis. Do you do it on the types of chemicals produced, the methods of production, the matter of disposal?

You know, I am very curious in finding out how the insurance industry decides how much to charge for its premiums to people who manufacture toxic chemicals or who dispose of or transport toxic chemicals. How do you do it?

Mr. **Cheek**. We are required by State law to look back at our previous loss history. In product liability, for example, we take statistics countrywide over a period of 5 years. The loss and expense experience in that period and the trend in it is the basis for setting the future rates.

The law is changing very quickly in this field and in many States we are finding that past experience is not really a useful guide when new decisions come down that overnight entirely change the whole basis of liability.

The *Beshada* case in New Jersey last year is an example. A productmaker in New Jersey is now in effect an insurer in perpetuity for any harm caused by his products because, the court said, a manufacturer may be held liable for failing to warn of a defect in his product even if at the time of his manufacture of same he did not and could not have foreseen the harm that it might cause.

But the short answer to your question is that we have to look backwards at actual loss and expense experience. We cannot speculate on the relative toxicity of a chemical or its reactivity with other chemicals, or its carcinogenicity. We have to look back at the aggregate of experience for that particular chemical maker and for chemical makers as a whole in setting product liability rates.

Mr. LEVITAS. Could you provide us, if you have it now, if not, provide it for the record, the premium cost increases that have occurred over the last 10-year period?

Mr. CHEEK. We can easily provide that.

Mr. LEVITAS. Would you do that? I would like to have it for the record.

Mr. CHEEK. In the product liability area?

Mr. LEVITAS. Whatever category. When you insure the ABC Chemical Co., how do you fix its premium when they are disposing of hazardous wastes?

Mr. CHEEK. In most of the big chemical companies we are as an insurance industry in what we call an excess or reinsurance posture. Most of the major chemical companies are to one extent or another self-insurers of their exposure. Often they are insured per occurrence as in the tens of millions of dollars which means it has to be a real disaster before their insurance is called upon to respond.

So that much of the data we would give you leaves out a very large universe, probably the major portion of the chemical manufacturing universe.

Mr. LEVITAS. Because they are self-insured.

Mr. CHEEK. Yes.

Mr. LEVITAS. We will be speaking to chemical companies before the hearings are over and I would like to ask them the same question.

Mr. CHEEK. We will give you what we have.

Mr. LEVITAS. There have been other cases where new technologies have come into play that have created insurance—new avenues of insurance coverage. The automobile, for example, the airplane.

Mr. CHEEK. Jumbo jets.

Mr. LEVITAS. That is right. All of those things have created new dimensions. I have a feeling that this is an area where it is going to happen a lot quicker than it has in these other areas. I see in the last few years and certainly in the next 4 or 5 years, I see just a real upward curve in lawsuits and claims.

Mr. CHEEK. So do we.

Ms. BIRNBAUM. And premiums.

Mr. LEVITAS. You may wish to submit something further for the record on how the insurance industry is looking to the future in trying to ascertain how they insure these risks as we are moving into a new area. I think that would be very, very helpful to us.

Mr. CHEEK. I would be delighted to do that.

[The information received from Mr. Cheek follows:]

Crum & Forster Insurance Cos.,
Washington, DC, October 29, 1984.

Mr. Robert S. Prolman,
Professional Staff Member, Subcommittee on Investigation and Oversight, Committee on Public Works and Transportation, House of Representatives, Rayburn House Office Building, Washington, DC.

Dear Bob: Thank you for sending me the transcript pages from my appearance before Congressman Levitas' subcommittee on July 27, 1983. I appreciate your reminding me of the information that I agreed to provide for the Subcommittee's record.

The progress of a hazardous substance from production through use, storage and treatment, to final disposal as a waste involves several lines of insurance, a fact that did not clearly emerge from my exchange with Mr. Levitas. I think it would help clarify the record if I described various coverages involved in our exchange.

First, when a hazardous substance is a "product," the coverage involved is product liability, which is usually sold as part of the manufacturer's Comprehensive General Liability (CGL) policy, which, with certain exceptions discussed below, provides insurance protection against any liability arising out of the operation of the business. The product liability component of the policy will cover the manufacturer's liability arising out of harm caused by the products he produces, whether that harm results from defects in the products, breach of express product warranties, defective product design, or failure to adequately warn of possible product dangers.

For example, if a manufacturer warrants that its product will remove grease and it fails to do so, his product liability coverage will compensate the product user for the resulting damages. Similarly, if the product is caustic, and the manufacturer fails to provide a product warning to this effect, his product liability coverage will provide coverage for the damages suffered by persons burned by the product.

As noted in my testimony, most of the chemical industry is self-insured for its product (and most other) liability, so that there is very little commercial insurance data that would indicate, in any meaningful fashion, the frequency and average amount paid in product liability claims against chemical manufacturers.

Indeed, the best data we can provide is the enclosed table from the Insurance Services Office, the industry's principal statistical and rate advisory organization, setting forth rate level increases for all product liability country-wide, for both basic and increased limits products liability coverage. It should be noted that the rate level changes in the table are those indicated by industry-wide loss and expense experience; they are not necessarily a reflection of actual price increases in the insurance marketplace. For the past several years, because of intense competition among insurance carriers, product liability insurance rates have generally lagged far behind the trend in loss and expense experience.

The second line of coverage involved in our exchange is the "sudden and accidental" pollution coverage commonly found in CGL policies. This coverage is designed to respond to situations in which the manufacturer's products or operations result in sudden and unintended pollution. For example, if a chemical tank on the manufacturer's premises ruptures, and floods a neighbor property, the "sudden and accidental" pollution coverage in the CGL policy will pay for any ensuing bodily injury or property damage.

Unlike loss and expense data involving product liability, losses and expenses associated with "sudden and accidental" pollution are not separately coded by insurers reporting their CGL experience to the Insurance Services Office. Thus, although the industry knows that claim frequency and average claim severity in pollution incidents are increasing, it cannot isolate precise pollution loss and expense experience from its other CGL data.

Because of the growing importance of pollution-related losses, the Insurance Services Office Executive Committee decided last month that, effective no earlier than January 1, 1986, all pollution coverage (except for that relating to the product liability or completed operations peril) would henceforth be excluded entirely from the CGL policy. "Sudden and accidental" and "non-sudden or gradual" pollution coverage would henceforth be provided under a separate pollution liability insurance form, whose loss and expense experience would be separately reported.

However, because the changeover will not be mandatory until January 1, 1987, there is likely to be little meaningful pollution liability insurance data available before the end of the current decade. And the credibility of such data as does become available will be affected by demand for the coverage and the frequency and severity of claims under it.

The third major coverage involved in our discussion is the so-called Environmental Impairment Liability (EIL) contract, which is designed to cover "non-sudden or gradual" pollution and thereby dovetail with the "sudden and accidental" coverage now provided under the standard CGL form. The EIL market is quite small, with a premium volume of perhaps $40 million last year, as contrasted with the $7.4 billion in general liability premiums during the same period.

The small size of the EIL market results not only from the relative novelty of the coverage (the first policy was written in 1973), but also because of the relative instability of the EIL reinsurance market and the high degree of uncertainty about the need for EIL coverage created by court decisions holding that transparently non-sudden damages are covered under the "sudden and accidental" language of the CGL policy. Some courts have gone so far as to hold that "sudden" is simply another word for "accidental," and that, as long as the insured's polluting act was not intentional, coverage is provided even for pollution incidents of many years' duration. These holdings have discouraged the growth of the non-sudden pollution liability insurance market.

As would be expected in such a small and fragmented market, EIL insurance loss and expense data is sparse and insufficient in either duration or dollar volume to be credible for rate making purposes. Indeed, as Mr. Levitas surmised during our exchange, rate-making in EIL, and in the pollution component of the CGL, is more a matter of judgment than of reliance on (occasionally non-existent) loss and expense experience.

Mr. Levitas was intuitively correct in identifying some of the factors that underwriters consider in granting and pricing pollution coverage. These factors include, as Mr. Levitas suggested, "the types of chemicals producted, the methods of production, (and) the manner of disposal." However, these considerations, and others, are applied with respect to a manufacturer's entire product line, rather than to individual chemicals, because all of his liability, from whatever product line, is covered by the contract. Only in rare instances (e.g., asbestos, swine flu vaccine) have specific products been explicitly excluded from a given manufacturer's product or environmental liability coverage.

It has been suggested on a number of occasions that insurers could isolate, and separately rate, individual products or wastes produced by insured manufacturers, on the theory that more dangerous products and wastes should carry a higher liability insurance premium than less hazardous substances. However, because of the paucity of experience with individual chemical products or wastes and the critical role that management attitude plays in loss prevention, it's simply infeasible to separately price the exposure for all, say, 20,000 chemicals produced by a single manufacturer. The expense would bear no relationship to the manufacturer's exposure. Moreover, volume is usually a more reliable indicator of potential loss exposure than either toxicity, reactivity, or even carcinogenicity. There is clearly more opportunity for leaks and spillage in handling hundreds of tank cars of a low toxicity product than in delivering a few drums of a highly toxic material.

Most chemical manufacturers' insurance coverage provides enormous aggregate limits (usually in the hundreds of millions of dollars), but does not come into play until the liability arising out of a particular occurrence has exceeded the manufacturer's self-insured retention, which will typically be on the order of tens of millions of dollars. The rates for the coverage provided under these circumstances largely reflect actual loss and expense experience or, more recently, reinsurers' perception of the exposure involved.

Although there is little data on the rates charged for EIL coverage for firms who cannot afford to self-insure their gradual pollution liability, we can tell you, on the basis of our three years (1981–1983) experience in the EIL business, that rates increased drastically (an average of 30 percent) in each year of the program, not because large numbers of claims were paid, but rather because a relatively small number of possible claims were reserved for very large amounts, requiring our reinsurers to sharply increase their prices to cover their potential exposure under the policies we had written. It is fair to say, given the instability of the legal regime governing pollution liability, that our European reinsurance underwriters grossly underestimated their loss exposure. After three years of steadily worsening experience, they simply withdrew from the market, and we were forced to follow suit this year.

Our experience in the EIL market was not unique. A year ago there were perhaps a dozen active EIL markets in the United States. There are now perhaps three. The principal reason for the shrinkage of the market is the almost total withdrawal of foreign reinsurers from the American pollution liability market. Court decisions like that in the Jackson Township case, where $15.6 million was awarded to 97 families in which there was no evidence of any clinical illness, and the incredibly extreme liability standards being proposed in both State legislatures and the Federal Congress, combined with very poor loss experience, have driven even the world's most adventurous underwriters out of the market.

It is my judgment, one I believe is shared by most of my colleagues in the industry, that the pollution liability insurance market will remain unstable for several years to come. Indeed, there may be a serious availability and affordability problem in pollution liability insurance as early as next year, when the final phase of the Environmental Protection Agency's Resource Conservation and Recovery Act financial responsibility regulations become effective for all hazardous waste storage, treatment and disposal facility owners.

The source of future instability will obviously not be loss and expense experience, since so little coverage is currently being written, but will rather be the unsettled state of the law governing liability for and coverage of harm caused by exposure to hazardous substances. Mr. Levitas was, as usual, perceptive in his comment that there will be "just a real upward curve in lawsuits and claims" in the environmental area.

Judging from the insurance industry's reaction to the Minnesota Superfund liability system (see enclosed article from the Wall Street Journal of October 23, 1984), and the violent conflicts in the House last summer over the "Federal cause of action" in H.R. 5640, it is likely that major insurers will wait until the law of pollution liability is more settled than it currently is before making a commitment to the pollution liability market.

Generally speaking, the industry has been able to insure tort liability in the United States for the past two hundred years because the common law evolved very slowly. As Congressman Levitas noted during our exchange, change in the "toxic tort" are "is going to happen a lot quicker than it has in these other areas." The very rapidity of that change cuts against the essential element in the insurability of any risk—predictibility.

I hope the foregoing is sufficient to answer the questions left unanswered during my appearance before the Subcommittee. I would be pleased to discuss these issues in more detail if you feel it necessary. I also look forward to visiting with you about the Subcommittee's report on its "victim compensation" hearings at your convenience.

Best wishes.

Sincerely yours,

LESLIE CHEEK III,
Vice President-Federal Affairs.

MINNESOTA'S POLLUTION STATUTE GENERATES BOYCOTT BY INSURERS

(By Eugene Carlson)

Minnesota is a paradox. Few states are so blessed in terms of educated workers, squeaky clean environment, honest government and productive industry. Yet few states in recent years have been so thoroughly bashed by their own business community.

Like North Woods wolves on the prowl, Minnesota business executives have ganged up on their state government, howling about high taxes and onerous regulation that they say have bled the state's business climate. The Legislature, cornered by the business lobby, has redressed a number of these complaints.

Now business smells blood again. The target this time is Minnesota's year-old Superfund law that deals with the problems of toxic waste. The focus of anger is a section of the law that lays out a new, strict standard for liability in the case of personal injury, if that injury can be traced to the delayed effects of toxic material. The standard is so tough that the insurance industry has taken an unusual step: It has stopped writing peronal-liability coverage in Minnesota for damages stemming from "non-sudden" pollution.

Example: A train crashes, chlorine leaks from a tank car, and people are injured by the fumes. That's a "sudden" occurrence in the eyes of insurers. Claims are covered by the railway's normal liability coverage. But cancer that a family says resulted from toxic chemicals leaching into their residential water supply over 20 years is a "non-sudden" occurrence. Coverage against claims from this sort of long-term pollution has dried up in Minnesota.

The Minnesota environmental-insurance boycott is being closely watched by other states, among them Massachusetts, Michigan, New Jersey and North Carolina. These states are studying Superfund-type laws of their own. Minnesota, with the first and only such state law to date is the model.

So far, Minnesota's Superfund experience hasn't been a model for anyone. Ask Gov. Rudy Perpich, who signed the Superfund bill into law in May 1983, after his predecessor had vetoed it a year earlier. Last week the governor was in London with a state economic development delegation, selling Minnesota as a swell place for British business to invest. But Gov. Perpich also had the awkward assignment of visiting Lloyd's of London. There, he listened to insurance underwirters explain the "Minnesota exclusion" that is now standard in the reinsurance policies that insurance companies buy from Lloyd's to cover their own risk in writing environmental-impairment liability (EIL) insurance.

When Lloyd's decided late last year that Minnestoa was a bum EIL risk, the rest of the industry fell in line.

The insurance industry says it has no choice but to give Minnesota the cold shoulder. Insurance executvies point to two parts of the liability section that they say are heavily biased toward plaintiffs. In the hands of a clever trial lawyer, the settlements could be enormous, the industry fears.

Under the "causation" section of the law, a defendant in a toxic tort case, say a company that handles hazardous waste, must prove that it didn't cause a worker's injury. Under common law, the burden of proof is traditionally the plaintiff's.

"Our conclusion was that if you can't keep causation away from the jury, the juring being sympathetic human beings, will find for the plaintiffs in virtually every case," says Leslie Cheek, vice president for government affairs of Crum & Forster, a property-casualty insurance holding company.

A second provision makes some toxic waste-generating companies liable for problems stretching back to 1960. And the liability is "joint and several," meaning that one defendant could get hit with all the damages if the others can't pay.

Critics also point out that Minnesota's victims aren't likely to be just the gritty smokestack industries normally associated with toxic waste. Most high-tech concerns cast off environmentally hazardous material as a manufacturing by product. This makes them potential Superfund targets. Attacking high tech in Minnesota is a jab in the gut.

Fans of Superfund, however, suggest industry fears may be overblown. EIL insurance itself is new and it is still a tiny market: about $40 million in premiums written nationwide last year, compared to $300 million in workers compensation premiums written in Minnesota alone, according to a state insurance survey.

"There's no history of claims data," says a state insurance official. "The industry's dealing with a new line and they don't know how to price it. It makes them overly cautious." Says Ralph Marlatt, president of the Insurance Federation of Minnesota: "We want to write this coverage. There's money to be made here. But all the parties have to sit down and come to some agreement."

That may just happen. Gov. Perpich says he'll gather the key players, including the Lloyd's underwriters, around a table in the next few weeks and discuss the feasibility of modifying the Superfund in the legislative session that begins Jan. 1.

And the two authors of the Superfund bill, while loyal to the principle, sound ready to compromise. Rep. Dee Long says that if a survey now under way shows the causation section to be a stumbling block, "then it behooves us to take a look at it. * * * I don't think we ever ought to pass something that's cast in concrete."

Superfund co-author Sen. Gene Merriam goes futher. "I think the only way to modify it is to get rid of the causation section if indeed that's what's causing the problem," he says. "It's a nice notion, but it may be ahead of its time."

Mr. CHEEK. If I could comment on one thing, historically the common law has tended to evolve, that is, the movement has been fairly slow but there has been a gradual adaptation to new kinds of liability and new concepts of liability. But there is some possibility that, as you suggest, that evolution is on the brink of becoming a revolution.

Mr. LEVITAS. I think so.

Mr. CHEEK. We have some concern about the concept that, as between an innocent injured party and an innocent product manufacturer, it is easier for the product manufacturer to be the insurer of that harm than otherwise. We see the law moving in that direction.

If that movement accelerates, then we may be the ones coming before you and recommending that the common law be arrested and that a nonfault kind of system be established.

Mr. LEVITAS. I predict that will happen. I was in the State legislature when we passed the no-fault insurance law and I remember who was there advocating it and I remember who was there opposing it.

Mr. CHEEK. That is right. We don't see in the data—we have to look backward—the evidence that that is yet translating itself into larger numbers of claims. There are certainly larger numbers of claims, but their costs have not yet become so uncontrollable that we cannot predict it and keep up with them.

But that day may come. I hope it doesn't frankly. I would be happy to provide something for the record.

Mr. LEVITAS. I think that would be very helpful and it might be useful even for your own industry to focus on that.

Mr. CHEEK. It certainly would, Mr. Chairman.

Mr. LEVITAS. I want to thank both of you very much for your testimony. It has been quite helpful and has opened up new thoughts for all of us on this subject and we appreciate your being here.

Mr. CHEEK. Thank you for having us.

Ms. BIRNBAUM. Thank you, Mr. Chairman.

Mr. LEVITAS. The next witness is Dr. John Beljan, provost and senior vice president, Wright State University, Dayton, OH. He is here representing the American Medical Association, and is going to be accompanied by Mr. Harry N. Peterson, director of division of legislative affairs, American Medical Association.

Gentlemen, if you would raise your right hand, please.

[Witnesses sworn.]

Mr. LEVITAS. We appreciate your being here for a number of reasons. First of all we are quite interested in the medical profession's view on the subject of toxic chemicals and specifically on the subject of one toxic chemical, the substance dioxin. I know, Dr. Beljan, that you were the chairman of a committee or study group, a task force on agent orange in which the compound dioxin is present, and therefore have a great deal of experience in this area.

In addition to that--this was just from my own perspective—when I read in the newspaper the resolution adopted at the meeting of the AMA in Chicago and then some subsequent action taken shortly after the original press report, I frankly was confused to begin with. I was bewildered to begin with and confused at the end and thought it would be very important to clarify for the record in these hearings—I know there has been other testimony, but in these hearings—just what occurred so we can put that one aside and get on to the substance of other matters in this regard.

So thank you so much, Dr. Beljan. We look forward to your testimony.

TESTIMONY OF JOHN R. BELJAN, M.D., PROVOST AND SENIOR VICE PRESIDENT, WRIGHT STATE UNIVERSITY, DAYTON, OH, REPRESENTING THE AMERICAN MEDICAL ASSOCIATION, ACCOMPANIED BY HARRY N. PETERSON, DIRECTOR OF DIVISION OF LEGISLATIVE AFFAIRS, AMERICAN MEDICAL ASSOCIATION

Dr. **Beljan**. Thank you, sir.

As you say, I am John R. Beljan, M.D., and I am senior vice president of Wright State University in Dayton, OH. I was the former dean of its school of medicine and I would like to say that I teach medical science and not law and with that stipulation, please, I would like to have that entered on the record.

I am currently a member of the Council on Scientific Affairs of the American Medical Association. I served as chairman of the Association's Advisory Panel on Toxic Substances that prepared the AMA's 1981 report on "Agent Orange" and dioxin contamination. Accompanying me is Harry N. Peterson, director of the Association's Division of Legislative Activities.

Mr. Chairman, we are pleased to have your invitation to appear here today to discuss the AMA's view concerning the human health effects of exposure to dioxin.

In 1981, the AMA House of Delegates adopted a report entitled "The Health Effects of 'Agent Orange' and Polychlorinated Dioxin Contaminants." Copies of this report were submitted to the subcommittee. I believe you have them in your possession, Mr. Chairman.

This report was developed by the Association's Council on Scientific Affairs and was based on the investigation of its Select Panel on Toxic Substances of which I was chairman. And with your permission I would like to take a few minutes after this testimony to describe how that was assembled.

This report was initiated because of concern about the reported adverse effects to humans from exposure to agent orange during the Vietnam conflict. Medical complaints noted by veterans included weight loss, liver damage, recurrent skin rashes, deformed offspring, stillbirths, cancer, sterility, personality changes, and other illnesses. The report, however, was not limited to studies involving exposure of U.S. forces to agent orange but included a review of all reported exposures during the last four decades.

Dioxin, TCDD, was present in agent orange as a byproduct of its manufacture. If you recall, agent orange is a 50/50 mix of 2,4,5-T, and TCDD, and dioxin is a byproduct contaminant in the manufacture of 2,4,5-T.

The information used in this study was the currently available scientific information published in the world's literature. This study by our panel was a major undertaking given the very substantial amount of literature reporting experience with animal and human populations that has been generated over the last four decades. This report states, "TCDD by itself is extremely toxic; along with botulinus bacillus toxin and aflatoxin, it is one of the most lethal organic chemical compounds known to man."

The report recognizes and describes the toxicity of TCDD, pointing out the varying toxicity among different animal species and the relationship between toxicity and the amount and type of exposure and ingress to the body. This position, formulated in 1981, is still the policy of the AMA.

The report concludes that the suggested adverse health effects on human beings attributed to dioxin exposure, there is conclusive evidence of a cause and effect relationship only with respect to chloracne. Chloracne is not an uncommon form of occupational dermatitis and may be caused by other chlorinated chemical compounds. It usually clears within several months after cessation of exposure, although severe chloracne may be persistent and has been known to last for as long as 15 years following cessation of exposure to the causal agent.

With respect to other human health effects that have been attributed to dioxin, TCDD, the Council on Scientific Affairs and its advisory panel concluded that there was insufficient published data subject to peer review to establish a definite relationship between exposure and adverse effects. The report reviews in detail the published scientific literature that supports these conclusions.

I would note that the report of the Congressional Research Service of the Library of Congress entitled, "Dioxin: Environmental Impacts and Potential Human Health Effects," published June 6, 1983, surveys the body of scientific opinion and its conclusions. This survey refers to and is consonant with the 1981 AMA report.

Mr. Chairman, we feel that the AMA has a continuing obligation to promote the pubic health in matters such as this and to inform the profession and the public of the most current information available. We note that this matter is not static and that new evidence will be reviewed as it becomes available. We do not intend to let this important matter drop.

Action taken by our House of Delegates last June calls for an updating of our report on agent orange and dioxin along with an active program to provide the public with the most accurate information available on dioxin. This review by our panel will begin next month. As a matter of fact it will be 2 weeks from today.

The findings are expected to be presented to the AMA Board of Trustees with subsequent consideration by the House of Delegates. We will inform you of our conclusions.

The AMA at present is also engaged in extending its studies beyond dioxin to the reproductive toxicity of other chemicals. A group of physicians with expertise in toxicology, occupational medicine, pediatrics and obstetrics has been asked to summarize the reproductive effects of chemicals in males and females, including prospects of mutagenicity.

The panel—by the way not necessarily all AMA members—has selected a group of chemicals commonly encountered in industry as an initial project, has developed a standard format for reviewing and describing the effects of chemicals, and is now summarizing the toxic effects of each. This process has been underway for more than 2 years and should be completed in about another year. We believe that this report will add substantially to current information concerning health effects of chemicals.

Another subject of great interest to us is that of the effects of toxic chemicals in waste dumps. Among the concerns are those that relate to the possible effects of the chemicals on drinking water, and effects on the public who are exposed through contact with agents through the skin or through the air. In addition to difficulties of identifying the effects of small doses over long periods of time, there is another concern stemming from the widely varying geologic characteristics of the disposal sites. There is also great variation of course, as you well know, among the sites in terms of the chemicals they contain.

While much scientific study is necessary on the problems hazardous wastesites may pose, it is important that data that is acquired and that is disseminated be sound.

Regarding the question of scientific evidence about human health effects of toxic substances, one significant point must be stressed. Positive findings in experimental animals may be suggestive, but they are not equivalent to positive findings in humans. This is especially true if there are great differences between the experimental animals and humans in terms of usual doses and usual routes of administration, and in terms of metabolism and system responses.

Accurate measures of exposure and of disease, and indeed the specific agents involved, are necessary. And it is almost always necessary to compare results with a group of nonexposed persons with similar characteristics before a definitive finding can be made about the health effects of exposure.

As I have indicated, on the broader issue of health effects of toxic substance exposure in general, the American Medical Association will continue to be active in reviewing the medical literature in this area. However, as I am sure you are well aware, we are talking about many different compounds and various ways in which the public may be exposed to these substances. I think you are aware we use the term "dioxin" but there are 22 isomers of that, 2,3,7,8-TCDD and in that family of agents there are at least 60 or 70 agents chemically related.

We urge the Federal Government and industry to continue to support necessary research in this area so that there will be better information on which to base future decisions related to toxic substance exposure, and they can be rationally made.

Mr. Chairman, we are appreciative for the opportunity to be here. We would like to assure you of the cooperation of and assistance of the association in addressing the investigation problems of this area and we would be pleased to answer any questions the subcommittee may have.

I would like, however, if I may, to just make two brief verbal addenda. One relates to the action of the House of Delegates and, two, how our committees are put together.

Let me first address the latter.

There is a body called the "Council on Scientific Affairs" which is elected by the membership which has within its structure individuals with broadly-based backgrounds in a variety of medical specialties. That council is the coordinating body for a variety of expert panels which are put together in which we draw experts from the United States both from the medical and biomedical community, members and nonmembers, who are experts in the area being addressed to review the world literature in terms of the subject at hand.

That was the committee I chaired and we did review the literature available as of 1981.

We will review the published available public literature available to us not in the New York Times but that which is in the scientific literature 2 weeks hence and in subsequent meetings to that initial meeting.

In regard to the unfortunate publicity regarding the action, the resolution of the last meeting of the House of Delegates, the resolution arose in the Missouri Delegation and was forwarded for review in the House of Delegates by means of the methodology of reference committees.

In those reference committees, although the whereases in the document are considered when they are recommended for adoption by the reference committee, only the resolves appear as official AMA policy.

I have in a previous hearing regretted some of the improvement language that was in the whereases, I was also bold enough to say that I thought Congress on occasion made imprudent comments as well. I can assure you that the AMA did not in effect endorse the language that was embodied in the whereases of that resolution but did in fact adopt as a social policy the two resolves, to wit, the first resolve that the American Medical Association institute an active public information campaign to get accurate information on dioxin before the public to prevent irrational reaction and unjustified public fright and to prevent dissemination of possible erroneous information; and be it further resolved that the AMA Council on Scientific Affairs be requested to update the 1981 report on dioxin.

I would assure you the AMA did not change its policy one bit. We stand by the report and are prepared to revise that report if warranted by critical review of the scientific literature.

Mr. **Levitas**. Thank you very much, Dr. Beljan, for that explanation as well as the testimony you have given us on the subject of dioxin.

I know we have a number of questions and I would like at this time to recognize my colleague from Georgia, Dr. Rowland.

Mr. **Rowland**. Thank you very much, Mr. Chairman, and Dr. Beljan, may I welcome you, my colleague, and Mr. Peterson. It is very nice to have you here.

Dr. **Beljan**. Thank you, sir.

Mr. **Rowland**. And contrary to what I may have heard Congress is a great institution and contrary to what Congressmen may have heard, medicine is a great institution.

Mr. **Molinari**. What about law?

Mr. **Rowland**. I purposely omitted that.

My good friend from New York and I have had a running commentary as doctors and lawyers often have, but it has been fruitful for both of us.

I was particularly interested in the resolution and of course you cleared up the AMA's stand and what is in the "resolves," and what it is not involved in the "whereases."

Dr. **Beljan**. That is right.

Mr. **Rowland**. I was particularly interested in the fact that this resolution was a product of the Missouri Delegation.

Dr. **Beljan**. Yes.

Mr. **Rowland**. And Missouri is where Times Beach is located.

Dr. **Beljan**. Right.

Mr. **Rowland**. We heard from the Mayor of Times Beach here a couple days ago about the illnesses of many, many people in Times Beach. She is convinced these illnesses came about because of the exposure to dioxin there.

Dr. **Beljan**. Yes.

Mr. **Rowland**. And yet the Missouri Delegation to the AMA didn't feel that dioxin was any particular problem. So I was wondering, had physicians from Missouri that may have had input into this resolution have any contact with the people from the Times Beach area? If so, what were their findings?

I found the testimony that the mayor gave somewhat astounding; many of the things that she said were somewhat astounding; and I have asked for some followup from physicians in that area to substantiate or refute many of the things she said. I would just like to have your comments on that if you do have some knowledge in that area.

Dr. **Beljan**. I don't have extensive knowledge and what I would tell you would be perhaps secondhand or hearsay information but I do believe that there were concerns in the Missouri Delegation that too much of the public information that had been released through the media and so forth was anecdotal, suggestive and if I could say, sir, contagious, and that in fact there were patients not from the Times Beach area approaching Missouri physicians with a variety of ailments and concerns about their environment and potential of dioxin and other agents in their immediate environs.

And if you will, there were, I think one of the motivating factors behind that was a sense of almost hysteria that had been generated by perhaps some of the anecdotal information and so forth that related to it. Undoubtedly some of our colleagues in the Missouri Delegation have treated or seen individuals from Times Beach. I am not personally aware, however, of those interactions or what they may have found.

Mr. **Rowland**. She mentioned one instance of a block where there were 15 homes and out of the 15 homes there, 7 of the homes had people with seizure disorders. I doubt if we would find that anywhere in the country out of 15 families.

That was just something that concerned me very much. Is that actually the situation that existed? Can you speak to that?

Dr. **Beljan**. I can't speak to that, sir, I do not know because it has not appeared in the literature that is available to us. I have learned not to rely necessarily on other media for sources of scientific information.

Mr. **Rowland**. From your experience then, in talking with physicians from that area, your experience is that much of what was thought to be symptoms or signs relative to dioxin was in fact not that at all?

Dr. Beljan. I do not want to make attributions to——

Mr. Rowland. I know I am asking you for hearsay.

Dr. Beljan. The concern that I think I saw reflected in the Missouri delegation was concern about how information regarding this agent had been made available to the public and how this was being reflected in the general medical practice of the Missouri physicians. I have not talked directly to physicians who were involved in the care of the Times Beach individuals. So it is a double hearsay thing in terms of their perceptions of what went on.

Mr. Rowland. Let me ask you something else then.

TCDD is an extremely toxic substance related to botulism and aflatoxin.

Dr. Beljan. Yes, sir.

Mr. Rowland. Since it is this toxic how would you explain the apparent lack of severe problems in humans who are exposed to it?

Dr. Beljan. First of all, the toxicity as you well know, Dr. Rowland, varies considerably even among experimental animals and even among families of experimental animals that are similarly related.

For example, one of the most sensitive animals is the guinea pig and yet there is a 500-fold difference between that and the hampster in the same general family.

The agent itself if it is exposed to air is rapidly focalized and under the influence of ultraviolet light will generally disappear within 24 hours. In the ground it binds tightly with soil and raises a whole series of questions, therefore, about bioavailability and ingestion and so forth.

There is a large body of evidence that would tend to indicate that there have been large populations who have been exposed to dioxin and it would appear as if the human being is one of those creatures who may be particularly resistant to it. I would not personally want to ingest it. On the other hand, I am aware of a critical review of the Oregon study, the industrial accidents that have occurred, I have just been provided with a copy of the report, primary report on the ranch hand study by the Air Force.

That is an exquisitely done statistical study.

I am aware of the early report of the Armed Forces Institute of Pathology with the cohort of Vietnam veterans surgical and autopsy material and I am impressed that there is not the clustering or patterning or increased incidences of problems that one would expect to see if the agent in fact were as dangerous as I would think it has been made out to be by some.

No question in the laboratory, it is a terrible agent. But as we pointed out, in the instances in which it has been used and in certain industrial accidents and where a whole town had been bathed in the stuff, and there is no clustering or unusual evidence of abnormality, it would indicate that there has been wide use that man may be particularly resistant, it may be a short exposure or even prolonged exposures of short duration are not particularly dangerous.

It would be useful perhaps, maybe not medically solubrious if we say the patterning and clustering that we see with other agents with direct kinds of relationships. But we have come to that conclusion as a body. The scientific panel on pesticides in Great Britain has come to that same conclusion. That is true of several others who have taken the scientific literature and done a critical analysis of it.

We have not seen some of the reported other studies that have been recently released. We would hope to have access to them. We would like to certainly have our panel and others review that in a critical framework. But from the standpoint of what is available to us in the current literature the AMA policy currently seems to be a reasonable one.

Mr. **Rowland**. Are you familiar with an instance about 2 weeks ago wherein the court ordered Dow Chemical Co. to release some information regarding dioxin.

Dr. **Beljan**. I am only aware of the event having occurred, having read it in the newspaper and hearing it on television.

Mr. **Rowland**. They talked about chloracne and it is well accepted that chloracne is the result of chronic exposure to——

Dr. **Beljan**. Or massive acute exposure as well.

Mr. **Rowland**. But there was also some revelation there that Dow Chemical had determined sometime back that fatalities may result.

Dr. **Beljan**. Again it is conjecture. It would be conjecture on my part. I have not seen the correspondence being referred to or what have you. I do know that words get garbled. For example, I am sure that they were aware of animal toxicity studies and I stipulated it is a terribly toxic agent in the laboratory animal. I think if I were faced with that, again conjecturely on my part, I would be concerned if there are some carryover effects elsewhere. I am not so sure—I have not seen that correspondence, I have not seen what was said, I don't know how it was interpreted.

I certainly believe that the Dow Chemical Co. generally is an ethical pharmaceutical company and conducts its operations in that framework.

Mr. **Rowland**. One other question I have, Mr. Chairman, regards immune systems. We have heard that some chemicals may break down immune systems. Is it possible that some chemicals may in fact activate immune systems?

Dr. **Beljan**. Yes, sir.

Mr. **Rowland**. So that a person might build up immunity rather than going in the other direction?

Dr. **Beljan**. Yes, sir.

Mr. **Rowland**. Do you have any idea about dioxin from that standpoint?

Dr. **Beljan**. We are aware that there are several laboratories conducting studies in the immune area, none of them have been published, none have made conclusive results. We heard of one study being done, testimony a week or two ago at a subcommittee of the Veteran's Affairs. It is a masters or doctoral thesis work currently in process. There is work by others who have shown some changes in the immune mechanism. But, yes, I would submit that this is a possibility with dioxin.

I would like to, again, we will incorporate whatever is available in the world's published literature on this in our review to commence very soon.

Mr. ROWLAND. Mr. Chairman, I have some other questions but I want to defer at this point.

Mr. LEVITAS. Thank you, Dr. Rowland, I appreciate your questions.

I will now recognize Mr. Molinari. We are going to try to get you out of here by 3:35.

Dr. BELJAN. Thank you, sir.

Mr. MOLINARI. Doctor, in your statement you refer to TCDD as being one of the most lethal organic chemical compounds known to man and yet it would seem that there is a lack of scientific literature or scientific evidence so far to be able to determine the impact upon human health.

Dr. BELJAN. Yes.

Mr. MOLINARI. The jury is still out on that, is that fair to say?

Dr. BELJAN. I think it is fair to say that in the laboratory it is a terribly hazardous compound, that the studies that have been available to us to date have not shown a direct carry-over experience with man.

Mr. MOLINARI. Is it true that dioxin is not comparable to other chemical compounds in terms of laboratory testing and that it doesn't exhibit the same relationships as to lethal doses administered to animals?

Dr. BELJAN. The problem in the literature is the problem I alluded to in my remarks, that people use the term "dioxin" and one does not know which of the 22 isomers is under discussion, or whether all of them are or any part of them; or the fact that in the dioxin-related family there are some 70-odd compounds, each of which has different toxic properties.

Mr. MOLINARI. The problem I read about was that in laboratory testing—I don't know which compound was involved, but I assume it was the same one administered to different animals—some animals didn't show the same dose response——

Dr. BELJAN. That is correct.

Mr. MOLINARI [continuing]. That others normally would. So it became more difficult to evaluate——

Dr. BELJAN. Yes.

Mr. MOLINARI. What quantity would be lethal, for example.

Dr. BELJAN. That is correct.

Mr. MOLINARI. Since we don't experiment with humans we don't know what quantity administered directly to an individual would be lethal.

Dr. BELJAN. That is correct.

Mr. MOLINARI. All right.

Dr. BELJAN. As I pointed out, even within families of related animals where one would expect there would be closer relationships in terms of dose effect responses that is not the case, specifically the hamster and the guinea pig is a 5,000-fold difference.

Mr. MOLINARI. Dioxin, correct me if there are some forms that don't fit into the general category, can be absorbed through the skin, can it not?

Dr. BELJAN. Yes.

Mr. **Molinari**. Although there may be a variance in the quantity that becomes lethal or harmful, isn't there some relationship between the toxicity of dioxin and the health hazard you might expect to result from exposure?

Dr. **Beljan**. It is extremely difficult to answer that question generally because one is talking I think in terms of dose response relationships with regard to either acute or chronic dosage, you are talking about the variability of subjects, we do know, for example, that in a variety of other ways that the very young and the very aged maybe because of their immune systems are quite different in their reactions.

We have the problem of route of ingestion, activity of the substance, the bioavailability of it; so it makes it very difficult, sir, for me to try to answer that question.

Mr. **Molinari**. I wonder how you can come up with the conclusion that it is indeed one of the most lethal organic chemical compounds known to man.

Dr. **Beljan**. We give it to animals and it kills animals. I would say that that would classify it as hazardous to animals.

Mr. **Molinari**. I understand that there are others that would be equally lethal or more lethal in doses administered to animals. What I am trying to do is see if there are other compounds, by comparison, which are equally or more toxic. You point out that there are so many varieties and chemical compounds within the generic term "dioxin" that sometimes we do not know what we are talking about.

Dr. **Beljan**. We know it is hazardous to animals; we do not have the same scientific basis with respect to man. That is desperately a missing area in terms of our fund of scientific knowledge, unfortunately. The dilemma, sir, about making assumptions about effects in animals and making translations to man is not restricted to dixoin. It is true with a whole host of almost all compounds; we always search for a per animal model and there is none. We look for other animals. The Ames test talked about earlier in terms of changes in microbes as a screening test for carcinogenicity, and that is imperfect. And cell growths and cell culture, and that is imperfect. Therefore it puts us in a difficult position of trying to look for accidental or inadvertent or other kinds of administration and then drawing data from that on some kind of epidemiological basis.

The fact is, however, there is no question in any of our minds that that agent has been used for 40 years has been used on the west coast extensively, it is still used in certain crop-dusting applications, and is less restricted in the United Kingdom than it is here. And so we—it is hard to reconcile then the fact that there is no clustering or unusual incidents of soft-tissue sarcoma or stillbirths or what have you in the populations of the west coast, particularly the large valley that has been treated for 30 years with this stuff.

Mr. **Molinari**. I am sure the good chairman has a number of questions, and I am going to abbreviate mine.

I would just like to close by asking this one question.

Dr. **Beljan**. Yes, sir.

Mr. **Molinari**. Taking your own statements that TCDD, by itself, is extremely toxic, along with the others you mentioned: that it is one of the most lethal organic chemical compounds known to man; and couple those with the reality that there is a community like Times Beach that is exposed to large quantities of this material and many of the residents have chosen to flee. Would that reaction really be characterized as an irrational reaction?

Dr. BELJAN. I do not think that that is irrational at all. I think that is a normal human reaction to fear and fear of the unknown and fear of a variety of things.

Mr. MOLINARI. What was the irrational reaction you referred to in your earlier testimony?

Dr. BELJAN. Is that in the resolution? It is again a preventive recommendation, it said that the American Medical Association institute an active public information campaign to get accurate information on dioxin before the public to prevent irrational reaction.

Mr. MOLINARI. That is the problem I have, though. We may be visiting some of those areas. If somebody came to the AMA and said we just learned there is a report that came out today that our neighborhood is loaded with whatever form of dioxin, and we all want to move, what shall we do?

What would you counsel them to do? We do get questions like that. You might have heard my comments before.

Dr. BELJAN. Sure, I understand.

Mr. MOLINARI. What would be your reaction to the people asking you that?

Dr. BELJAN. I think that I need to have more facts than are currently available to make that kind of judgment. If you would ask me the question, would I live there—because I heard you ask that previously of witnesses—that is a very difficult question to answer because I for one am comfortable with the Missouri environment, but I would have to respond to a variety of other kinds of criteria.

Mr. MOLINARI. Let me ask you a tougher question. Would you let your family live there?

Dr. BELJAN. That is the point I was coming to. If I had kids that would grow up in the dirt and eat the dirt, probably not. On the other hand, my last teenager is leaving the nest, that is a different lifestyle and different situation, and I do not think my wife and I are going to be eating soil, or in a position to be doing that. That is a totally different kind of situation.

So again it is hard to give you a general reaction to that kind of question. I can understand the public's concern. I can understand their worry about being in an area in which there is heavy dioxin exposure, and yet the documented public literature would indicate that we do not have the evidence that says that. So that does not resolve your problem because your problem is one, also, of public perception and public concern and those are as important to you as legislators as the scientific data, obviously, would be to the medical science. That does not say we are not concerned.

Mr. MOLINARI. I am sure of that.

Thank you, Mr. Chairman.

Mr. LEVITAS. Thank you.

I am going to be very brief because I do want to save time for Dr. Rowland. Let me ask you this and it follows up precisely on what Mr. Molinari was saying. I think the medical profession occupies a very special role in this entire subject area; and it occupies a very special role to the public generally, and to policymakers such as ourselves.

That role, while it is one that certainly should try to avoid unnecessary fear in the public, also, if it has to err, again should err on the side of protecting the public from undue exposure to potential hazards.

For that reason—and I am not trying to place any judgment—but I feel that the resolution that was adopted by the house of delegates of the AMA really does a disservice to the public because it comes from the medical profession, the organized medical profession.

I think it is a perfectly rational thing if a tank car containing TCDD broke down in my neighborhood, I do not have any hesitancy whatever to tell you what I would do, I would get the hell out of there, my wife, my family, everybody, get them out of there, because we make decisions based upon potential risk, and if somebody told me that one of the most lethal organic compounds known to man has just been spilled on the streets of my neighborhood I think I would have to really be nuts not to get out of there.

But here is my question to you——

Dr. BELJAN. Let me ask you the question, how long would you stay out of there?

Mr. LEVITAS. Probably until somebody assured me—if I were going to look for scientific certainty, it would be at that end. It would be when I make the decision to go back.

Dr. BELJAN. I agree. I would be with you. I would be moving out of there too with that kind of spill.

Mr. LEVITAS. I would be more inclined to move out on the basis of reasonable likelihood and more likely to expect scientific certainty to move back in. That is just speaking for myself. But that gets right to my question.

In prudent policy action, whether it be legislative action or medical action, is it not frequently the case that action is taken on something far less than scientific certainty? Based on reasonable likelihood, for example?

Dr. BELJAN. Absolutely, but I would like to differentiate action from what is fact, and those are very important concepts for a physician.

There is responsibility in other professions, too, and maybe that was part of the resolution. It is very difficult for a mother with a youngster to look at someone with a child and have an allegation made of potential problems, or that kind of anecdotal thing. How much balancing was done in the presentation of that information? Damn little, sir. That was a concern of our Missouri colleagues.

I would agree that there are many decisions in the public policy area that have to transcend fact alone but understand that our responsibility in the Council on Scientific Affairs is to deal with facts and then to adjust that fact as appropriate for the public situation.

Mr. LEVITAS. I am confident you will do that in your committee and your committee will do that and this recent report we have referred to that came out last Friday, I think it was, Thursday or Friday, by NIOSH or somebody will contribute to it. But Dr. Rowland for the last week has continually proudly made disclaimers by saying "I am not a lawyer" and then proceeded to pontificate on legal matters, which is his privilege to do.

Well, I am not a physician, but I suggest that based on my experiences with physicians that there are treatments administered every day where the treatment that the physician executes does not have very scientific certainty; that is that the particular treatment will treat or remedy the ailment involved, but it is taking the action based upon "What can I do to maximize the health of this individual?" People who are suffering from some range of diseases, for example, may get treated with broad spectrums of antibiotics and maybe it will hit someplace along the line. But you do something. You just do not sit back and wait until you have an absolute diagnosis of what the disease is before you treat it.

Dr. **Beljan**. That, sir, is the art of medicine, and there is art in science and in both of our professions.

Mr. **Levitas**. Thank you.

Mr. Rowland.

Mr. **Rowland**. I know you have to catch a plane and I would like to talk with you and ask a lot more questions, but I would first like to make this comment. I do have a problem with the word "irrational" in the resolution. If we are referring to the Times Beach situation, the EPA told these people it is a bad situation. They moved out based on that. I do not think their moving out was irrational. I do have a little problem with that word if it was used in that context.

What this hearing on victim compensation law is talking about is the possibility of creating a whole new area of toxic tort law which is relatively new to the trial attorneys, who have said so. I have been concerned about the developing of an area that will be mated more to the benefit of the trial lawyers than it will be to the people injured. You have been listening to some of the testimony here in the hearings?

Dr. **Beljan**. Yes, sir.

Mr. **Rowland**. Would you briefly give us your feelings on that? I know in the area of medical malpractice that the premiums for malpractice have just absolutely gone out of sight and a lot of that has been on the basis of frivolous suits that have not ever gotten to court. I am just concerned that we may be opening up another entire area. Would you briefly respond to that?

Dr. **Beljan**. Well, sir, I do not believe that the AMA has developed a policy related to this, so I do not want to speak for the AMA. There is certainly AMA policy that says if there has been injury there ought to be fair compensation.

I guess I would not like to speculate, but I do share personally a concern about spawning of excessive lawsuits and things of that sort, but there is no firm AMA policy regarding this specific area of new toxic tort legislation, and I think it is one that needs to be addressed and hopefully we can come back with a recommendation regarding that.

Mr. **Rowland**. Thank you both very much for being here. Thank you, Mr. Chairman.

Mr. **Levitas**. Thank you, Dr. Rowland.

Thank you, Dr. Beljan, and Mr. Peterson, you have been extremely helpful to us in what we are attempting to do, and I want to express my thanks to you for your attendance today. You can catch your plane now.

Dr. **Beljan**. Thank you very much.

Mr. **Levitas**. I would like also to express my appreciation to the witnesses who over the last several days have given us the benefit of their thinking. During our hearings in these last few days on victims compensation, we have heard from citizens who believe they have been affected by the presence of hazardous waste in the environment, and we have heard from those in the chemical industry, the legal community, the medical and scientific community. And today we heard from the environmental community and insurance industry, as well as the American Medical Association. Obviously that which we have heard has not exhausted the subject matter, nor have we necessarily heard from all the different groups and affected parties. Further, as we expected, our hearings did not resolve the controversies that surround the area of human health effects, nor did we eliminate the scientific or medical barriers to establishing cause-effect linkages between hazardous waste and human health. The subcommittee intends to review the record of the past several days very carefully as it considers how we should proceed in the question of victim compensation.

Among the things we intend to consider is the possibility of a few additional days of hearings so that we may hear from others in the medical community, such as people from the centers for disease control, Dr. Rowland, which you mentioned on a couple occasions; and from State officials, particularly those that have already taken some steps along the lines that Congress is contemplating which could include California, as well as Minnesota officials.

Further, with respect to making the record of these hearings as complete as possible, the hearing record will remain open for 3 weeks without objection to enable any other interested parties who may wish to submit comments to do so.

I have already announced some of our tentative plans for future hearings in the whole matter of hazardous waste cleanup, Superfund and the like, and we will announce in the next several days the schedule of hearings for the month of August and the weeks following after we return from the congressional recess. But there will be hearings scheduled during the district work period in August. Again, with my appreciation to the witnesses who have testified during this series of these hearings, I find no further business before the subcommittee and, therefore, the subcommittee stands in recess subject to the call of the Chair.

[Whereupon, at 3:35 p.m., the subcommittee adjourned, subject to the call of the Chair.]

HAZARDOUS WASTE CONTAMINATION OF WATER RESOURCES

(Compensation of Victims Exposed to Hazardous Wastes)

TUESDAY, NOVEMBER 8, 1983

House of Representatives,
Subcommittee on Investigations and Oversight,
Committee on Public Works and Transportation,
Washington, DC.

The subcommittee met, pursuant to call, at 10 a.m., in room 2167, Rayburn House Office Building, Hon. Elliott H. Levitas (chairman of the subcommittee) presiding.

Mr. Levitas. The subcommittee will please come to order.

This morning, the Subcommittee on Investigations and Oversight of the Committee on Public Works and Transportation continues its inquiry into the matter of hazardous waste contamination of the Nation's water resources, and as part of that inquiry, an examination of the problems that individuals have in obtaining compensation for the health and financial problems they face due to the presence of toxic wastes in their environment.

Earlier this year, in July, the subcommittee held several days of hearings on the subject, at which time we heard from a number of individuals—lawyers, doctors, EPA scientists, environmentalists, representatives of the chemical industry, and some victims as well.

The testimony that we heard clearly pointed out that there are uncertainties about the linkages between toxic wastes and human health problems. It also illustrated that there are limits in our ability to resolve absolutely these questions due to medical and scientific factors.

We also heard differing views on the adequacies and inadequacies of existing remedial or compensatory mechanisms, be they in the courts, workman's compensation, or the industry.

And finally, we heard differing views about the changes that many believe are needed. Some have argued that nothing need be done; others, that changes in either or both Federal and State laws are needed.

Indeed, it seems that the testimony revealed that the victim compensation issue is multifaceted, with perhaps as many considerations to be dealt with as there are toxic chemical wastes.

However, the testimony we have heard to date also clearly shows that there are individuals who live near or adjacent to hazardous waste sites that have serious health problems which they and others believe are associated with the hazardous wastes at those sites.

In a few cases, some of these individuals are getting compensation for their problems through the courts. But, it appears that the vast majority of people who believe they have health problems that are caused by hazardous wastes are not being compensated.

In part, this appears to reflect shortcomings not only in our medical and scientific capabilities, but in our laws as well. Indeed, it would appear that the system itself is in large part an impediment to the compensation of victims of hazardous waste pollution.

Under the Superfund law, we, as a Nation, will compensate for damages to our natural resources, but we will not compensate those who believe their very well-being has been impaired due to exposure to toxic chemical wastes. In short, we will pay for damage to trees but not for damage to people.

Certainly, it would seem that some change is in order. There remain, however, questions about just what should be done, and whether it should be done at the Federal level, or at the State level. I suspect that there will be a need for changes at both levels, and we look forward to hearing from today's witnesses who are particularly well qualified to enlighten us on these matters.

Before I invite the witnesses, I would inquire whether my good friend, the gentleman from Florida, Mr. Shaw, has an opening statement.

Mr. SHAW. Yes, I do, Mr. Chairman. I would first of all want to express my appreciation. I am sitting here in place of the ranking member, Mr. Molinari, who is on assignment for the President at the present time.

I also want to extend a cordial welcome to our witnesses. It is a rare opportunity for us to be able to engage in a frank exchange of views on the record with our counterparts from the State legislatures. I trust their experiences with toxics tort victim compensation will prove particularly enlightening.

I am pleased also that the Assistant Attorney General, Paul McGrath, will be appearing before the subcommittee today. Among other things I would hope his testimony would enable us to better understand why the administration has chosen to elevate the victim compensation issue to Cabinet-level policymaking, without the hyperbole I have recently seen in reaction to an OMB briefing memo which was selectively leaked some months ago.

Mr. Chairman, I want to commend you for initiating and now continuing the subcommittee's hearings on the victim compensation issue. I know I speak as well for the gentleman from New York, the ranking minority member—Mr. Molinari—in expressing their thoughts.

Victim compensation has, I suspect, proven to be a more complex issue than many of us considered when the subcommittee began its inquiry last July. I have been quite impressed by the testimony of the witnesses I have heard to date. Their views, although sometimes directly contradictory, have enabled the subcommittee to build a substantial record on the subject.

The testimony we have previously heard, together with that we will receive today and tomorrow, perhaps gives us an indication of why it was so difficult and ultimately impossible for the Congress to include victim compensation provisions in the 1980 enacted Superfund legislation. To my knowledge, an extensive record on the issues simply did not exist at that time. It seems to me that this subcommittee hearing, together with those of other committees with jurisdiction over the subject matter, will better enable the Congress to fashion well considered remedial legislation appropriate to the scope of the problem.

With that by way of introduction, Mr. Chairman, I again thank you for scheduling these hearings and look forward to a productive 2 days of hearings.

Thank you.

Mr. LEVITAS. Thank you, Mr. Shaw. Thank you for your comments.

Let me say that our colleague, the ranking member on this committee, Mr. Molinari, who, as you said, was unavoidably not able to be here today, carrying out a mission at the request of the President, truly has taken the lead in this entire matter of hazardous waste. I think it is no understatement to say had it not been for his persistence and urgings, the hearings we began 2 years ago would not have been undertaken. I know he wanted to be here, and I know he appreciates your filling in for him. He told me he had spoken to you about this, and I appreciate your participation.

Does any other member of the subcommittee have an opening statement to make at this time? If not, we are very pleased to have a colleague of ours with us today, a member of the full committee, who for a variety of reasons has played a very key role in our investigation and the whole subject of dealing with toxic wastes. In fact, yesterday, Bob, at a meeting in Memphis which was chaired by our colleague Don Sundquist, you had representation there. I know you wanted to be there, and your name was invoked on several occasions. I am sure that your interest preceded and extends beyond the immediate fact that you happen to represent the district in which Times Beach lies, but without doubt that has given you a special insight, as the citizens and witnesses from Times Beach and Imperial who have already testified before our subcommittee so poignantly demonstrated in their testimony before us. So we are glad to have you back with us today. You may proceed as you so desire.

TESTIMONY OF HON. ROBERT A. YOUNG, A REPRESENTATIVE IN CONGRESS FROM THE STATE OF MISSOURI

Mr. YOUNG. Mr. Chairman, because I want to move through the statement as fast as I possibly can, I don't want to forget to invite you out to the Metropolitan St. Louis area if you feel the subcommittee would be able to do that. I think it would be very interesting.

I would like to take this time to thank you for allowing me to appear before you today and share with you some of the very startling facts about the facts of hazardous waste. I also want to commend you for holding these hearings, because I feel the area of victim compensation due to hazardous waste contamination is an issue which will continue to plague America well into the next century.

I hardly consider myself an expert on the plight of victims. I honestly believe that I do have a contribution to make as I have grown all too familiar with the burdensome ordeal of reconciling one's life after such a catastrophic incident. My congressional district contains several dioxin-contaminated sites, as well as the famous—infamous Times Beach. Over the last year I have had to head the battle for Federal disaster assistance so that the thousands of residents could be placed in temporary housing, be provided with necessary emergency health care for injuries as well as food and clothing after a devastating flood ravaged the area in December 1982.

However, recovering from any flood is always a monumental task; however, to recover from a major toxic contamination is a nightmare.

Ladies and gentlemen, I am not exaggerating when I tell you that I, along with the residents of Times Beach, worked feverishly for months to convince EPA that the residents were exposed to a deadly chemical dioxin. It was an arduous, sometimes bitter, struggle for us to insist that immediate relocation was the only viable alternative until remedial action, whether on a temporary or permanent basis, could be found.

I am very sorry to sit here before you today and tell you that this was only the beginning. At this very moment we are engaged in these hearings, there are Times Beach residents who are still coping or grappling with the devastation of dioxin. It has been over a year since dioxin was discovered in Times Beach, and it is hard to realize that these people are still resolving fundamentals that seriously affect their lifestyle. I am talking about fundamentals which are crucial—fundamentals like a home, their health, well-being of their families, and their future.

As of October 23, 1983, only 43 properties in Times Beach have been bought out. Before anyone gets excited about the high number, I want to quickly add that is 43 pieces of property out of a possible 970. I can almost predict everyone's comment; and that is, EPA, FEMA, and everyone involved is trying to reconcile these issues as quickly as possible. Well, I can speak with authority when I say that I am aware of the efforts of FEMA and EPA and all the others involved, because I have been working right along with them since day one.

But the facts speak for themselves. I wholeheartedly concur when the headline reads "Missourians Forced Out By Dioxin Are Impatient, Distrustful and Worried," for all of these adverbs apply to me as well. The citizens of Missouri and the Nation have become increasingly aware of the serious health threats to the public health by the discovery of dioxin. However, when I have asked health experts in the field just what the health effects are of dioxin, no one, not one single person, could give me a straight specific answer. All I am told is that "it needs to be studied more" and "we're working on it," things like that.

However, I have noticed that the Center for Disease Control still continues to issue health advisories. I just feel that communication needs to be improved and the facts need to be made available now.

In response to several problems of the dioxin contamination, the Governor's task force has issued a final report calling for a super bunker to be built in Times Beach to house some 500,000 cubic yards of soil, or 50,000 truckloads, of dioxin-contaminated soil. I will make that—Mr. Chairman, I would like to make that report a matter of your committee's record.

Mr. LEVITAS. Without objection so ordered.

Mr. YOUNG. I question this proposal for several reasons. Primarily I am concerned about the structure being located in a flood plain or prone area. There are a myriad of other concerns about the construction of the bunker. There is also the very serious matter of the permit to be issued for the project. Cost estimates have been quoted at $200 million. May I remind you that this is $200 million just for a temporary solution?

My final concern is the soundness of the bunker from an engineering standpoint. Is there a danger of another public health hazard in 5 or 10 years?

During your July hearings, Mr. Chairman, many of the Times Beach residents provided a litany of medical problems and ailments that the citizens have linked directly to dioxin. This may—they are asking this subcommittee to provide some kind of victim compensation for taxpayers exposed to hazardous waste. I am aware of the efforts to include these kinds of provisions in prior legislation, and why, because of certain controversies, why they were not included.

It is not my intention to discuss the differences between acute toxicity as opposed to chronic toxicity and the probability of risk to victims genetically transmitting latent diseases or illnesses including cancers or birth defects. That I will leave for this distinguished panel which will appear before you today. However, it is my intention to encourage the subcommittee to arrive at some answer to these questions and provide Congress a clear direction.

Is it really a matter of our lack of scientific data to make these decisions, or is it simply a matter of cost? Does it cost too much money to find out the health effects? I believe building a super bunker will only defer many of these questions and not solve anything with regard to health risks and proper compensation.

It is clear to me that the scientific/medical community has adhered to the position that we do not have enough information to conclusively determine that persons are suffering as a result of toxic contamination. However, there are literally thousands of people, many in my district, that demonstrate medical problems that are at least connected to exposure of high levels of dioxin.

Lawyers and scientists offer no relief on the subject of how difficult it is to present and prove with sufficient evidence a toxic chemical tort case. The only thing a defense attorney can do is to provide enough negative facts and try to relax requirements for hard evidence in order to clear the procedures for a victim's just compensation.

What the subcommittee needs to determine for the American people is—Mr. Chairman, I have about five different questions here, and I think I will skip them because the other members are behind me.

The question of compensation, the long-term effect. And is this problem of such a magnitude that it requires an immediate Federal response? Mr. Chairman, all I can say is that no one knows how large a problem we are really faced with. What I do know is that the problem is large enough that it dictates a public policy be determined on a higher priority basis. In Missouri alone there are some 230 sites which are under investigation. This is a staggering number and easily demonstrates the need for congressional direction.

In conclusion, I want to stress that it is only through the leadership of this committee that I can envision a strong sense of hope which will enable us to grasp the complexities of the issue of dioxin.

Your efforts to continue to diligently monitor and oversee our Nation's Hazardous Waste Program are sorely needed. They will continue to be instrumental and effective in maintaining a policy that protects the health and safety and welfare of Americans.

I hope my remarks have been of value to you, Mr. Chairman, and the committee. And it is my sincerest wish that no other member should ever be faced with this most serious tragedy.

Mr. Bliss is like Dolly Levi, I think. He just spread that thing all over my district, and it just seems almost an impossible task at this point to try to resolve this very serious health problem. I appreciate the time of the committee, Mr. Chairman.

[The statement of Congressman Robert Young and the "Final Report of the Missouri Dioxin Task Force" follow:]

STATEMENT OF HON. ROBERT A. YOUNG

Mr. Chairman, and members of the subcommittee, I would like to take this time to thank you for allowing me to appear before you today and to share with you some very startling facts about hazards of chemical waste which I believe you will find very pertinent to your mission.

I also want to commend you for holding these hearings because I feel that the area of victims compensation due to hazardous waste contamination is an issue that will continue to plague America well into the next century. I hardly consider myself an expert on the plight of victims who have been shattered by the hazards of chemical waste, I earnestly believe that I do have a contribution to make as I have grown all too familiar with the burdensome ordeal of reconciling one's life after such a catastrophic incident.

My congressional district contains several dioxin-contaminated sites, as well as the infamous Times Beach. Over the last year, I have had to battle for Federal disaster assistance so that the thousands of residents could be placed into temporary housing, be provided with necessary emergency health care for injuries, as well as food and clothing after a devastating flood ravaged the area in December, 1982. Recovering from any flood is always a monumental task, however to recover from a major toxic contamination is a nightmare.

Ladies and gentlemen, I am not exaggerating when I tell you that I, along with the residents of Times Beach, worked feverishly for months to convince EPA that the residents were exposed to a deadly chemical—dioxin. It was an arduous and sometimes bitter struggle for us to insist that immediate relocation was the only viable alternative until remedial action, whether on a temporary or permanent basis, could be found. And I am very sorry to sit before you today and tell you that this was only the beginning.

At this very moment, as we are engaged in these hearings, there are Times Beach residents who are still coping and grappling with the devastation of dioxin. It has been over a year since dioxin was discovered in Times Beach and it is hard to realize that these people are still resolving basic fundamentals that seriously affect their lifestyles. And I am talking about fundamentals which are crucial—fundamentals like a home, their health, the well-being of their families, and their futures. As of October 23, 1983, only 43 properties in Times Beach have been bought out. Before anyone gets excited about the high number. I want to quickly add that that is 43 pieces of property out of a possible 907!

Yes, I can almost predict everyones next comment. And that is "EPA, FEMA, and everyone involved is trying to reconcile the issue as quickly as possible." Well, I can speak with authority when I say that I am aware of the efforts of FEMA, and EPA and all of the others involved because I have been working right along with them since day one. But the facts speak for themselves and it is still a traumatizing, almost hopeless ordeal at times for these residents.

I wholeheartedly concur when a headline reads: Missourians forced out by dioxin are impatient, distrustful and worried. For all of those adverbs apply to me as well.

The citizens of Missouri, and the Nation, have become increasingly aware of the serious health threats to public health and the environment posed by the discovery of dioxin. However, when I have asked experts in the field just what are the health effects from exposure to dioxin—no one, and I mean not one single person could give me a straight, specific answer.

All I am told is that it "needs to be studied more" and "we are working on it," etc. However, I have noticed that the center for disease control still continues to issue health advisories. I just feel that communication needs to be improved and the facts need to be made available—now!

In response to the severe problem of dioxin contamination, the Governor's task force has issued a final report calling for a "super bunker" to be built in Times Beach to house some 500,000 cubic yards of soil, or 50,000 truckloads of dioxin contaminated soil.

I question the proposal for several reasons.

Primarily, I am concerned about the structure like this being located in a flood plain or flood prone area. And there are a myriad of other concerns such as the construction of the bunker, again, the health and safety of the public, cost and timing factors, environmental concerns and public reaction. There is also the very serious matter of the permit to be issued for this project. Cost estimates have been quoted at 200 million—may I remind you that this is 200 million dollars for a temporary solution. My final concern is the soundness of the bunker from an engineering standpoint—is there the danger of another public health hazard in 5 or 10 years?

Mr. Chairman, during your July hearings on this subject, the mayor of Times Beach provided a litany of medical problems and ailments that the citizens had linked directly to dioxin. The mayor was asking this subcommittee to provide some kind of victims compensation for taxpayers exposed to hazardous waste. I am aware of the congressional efforts to include these kinds of provision in prior legislation, and why, because of certain controversies, why they were not included.

It is not my intent to discuss the difference between acute toxicity as opposed to chronic toxicity, and the probability of risks of victims genetically transmitting long latency diseases or ailments including cancers, or birth defects, or genetic mutation. That, I will leave for the distinguished panel which will appear before you tomorrow. However, it is my intention to encourage the subcommittee to arrive at some answers to these questions and provide the Congress with a clear direction on what is proper justice for victims that have suffered from toxic waste exposure.

Is it really a matter of our lack of scientific data to make these decisions, or is it a matter of cost—does it simply cost too much money to find out the health effects: I do believe that building a super bunker will only defer many of these questions and not solve anything in regards to health risks and proper compensation.

It is clear to me that the scientific/medical community has adhered to the position that we do not have enough information to conclusively determine that persons are suffering as a result of toxic contamination. However, there are literally thousands of people, many in my district, that demonstrate medical problems that are at least connected to exposure of high levels of dioxin. Lawyers and scientists offer no relief on the subject of how difficult it is to present and prove, with sufficient evidence, a toxic chemical tort case. The only thing a defense attorney can do is to provide enough negiative facts and try to relax the requirements for hard evidence in order to clear the procudures for a victim's just compensation.

What this subcommittee needs to determine for the American people is:

1. Are victims having extreme hardships in receiving compensation for their injuries?

2. What are the scientific and medical requirements associated with demonstrating a cause-and-effect of exposure to dioxin and the injuries from that exposure?

3. What are the institutional and legal barriers that are currently preventing or hindering victims compensation?

4. Is there a problem of such magnitude and urgency that it requires an immediate Federal response?

5. If a Federal response is needed, what is the appropriate and judicious response we in Congress can provide.

Mr. Chairman, all I can say is that no one knows how large a problem we are really faced with. What I do know is that the problem is large enough that it dictates that a public policy be determined on a high priority basis.

In Missouri alone, there are some 230 sites which are under investigation or which have been investigated for dioxin. Those staggering numbers should easily demonstrate the need for Congress' direction.

In conclusion, I want to stress that it is only through the leadership of this committee that I can envision a strong sense of hope which will enable us to grasp the complexities of the issue of dioxin.

Your efforts to continue to diligently monitor and oversee our Nation's hazardous waste program are solely needed. They will continue to be instrumental and effective in maintaining a policy that protects the health, safety and welfare of Americans.

I hope my remarks have been of value to you. And it is my sincerest wish that no other Member of Congress should ever be faced with this most serious tragedy.

FINAL REPORT OF THE MISSOURI DIOXIN TASK FORCE

---

submitted to
Governor Christopher S. Bond

OCTOBER 31, 1983

FINAL REPORT OF THE
MISSOURI DIOXIN TASK FORCE

SUBMITTED TO
GOVERNOR CHRISTOPHER S. BOND

October 31, 1983

October 31, 1983

Honorable Christopher S. Bond
Governor
State of Missouri
State Capitol
Jefferson City, MO 65101

Dear Governor Bond:

I hereby convey to you the final report of the Dioxin Task Force as requested in your executive orders 83-5 and 83-13.

In the eight months since its inception in February of this year, the Task Force has studied the volume of information on dioxin in the literature and as presented by experts in the field. The recommendations within this report reflect that study.

Please accept this report as adopted unanimously by the Dioxin Task Force.

Respectfully submitted,

James A Finch Jr

James A. Finch, Jr.
Chairman
Governor's Dioxin Task Force

JAF:brd

Definition of Dioxin

This report deals with one extremely toxic member of a class of compounds commonly called "dioxins". Within the 75 possible chlorinated dioxins, there are 22 isomers of tetrachlorodibenzo-p-dioxin (TCDD). In Missouri, the contamination is almost exclusively with one highly toxic member of this family, the member "2,3,7,8-tetrachlorodibenzo-p-dioxin". For simplicity and unless otherwise stated, this report uses the terms "2,3,7,8-TCDD", "TCDD", and "dioxin" interchangeably, all referring to one member of a family of compounds.

INTRODUCTION

On February 14, 1983, Governor Bond, by Executive Order, established the Governor's Task Force on Dioxin. It will be dissolved upon submission of this Final Report.

The Executive Order forming this Task Force included a charge to: "examine and evaluate all known methods, processes and technologies for the destruction and containment of dioxin, particularly as it exists as a contaminant in soil and sediment at various locations in Missouri;" and to "examine and evaluate the public health dangers associated with dioxin, particularly with respect to dioxin as it exists as a contaminant in soil and stream sediment at various locations in Missouri." The Task Force was then charged to "recommend a practical and effective plan of action for implementing comprehensive and permanent solutions to the public health and environmental problems caused by dioxin contamination in Missouri." The Executive Order mandated an interim report concerning the site at Times Beach as well as this final report.

In fulfilling the charges to examine public health and environmental problems and to examine and evaluate methods, processes and technologies the Task Force has examined extensive scientific literature and has heard testimony by a wide spectrum of experts from universities, governmental agencies, industries, and the public. It has heard over 50 hours of expert testimony and been provided with 10,000 pages of reports, scientific documents, and other related reading materials. In addition, in order to gain a better understanding of the Missouri problem, the Task Force made site visits to the St. Louis and Verona areas.

On June 1, 1983, the Task Force submitted its Interim Report to Governor Bond. It represented the preliminary opinions of the Task Force concerning immediate, yet temporary, remedial measures to be applied at Times Beach. In addition, the Report addressed the Minker and Stout sites because the Task Force believed there was sufficient urgency for interim actions at those sites. The report included important background materials and assessments of proposed dioxin destruction and remedial technologies.

This Final Report addresses the Governor's directions by giving an assessment of health effects based on currently available knowledge and by recommending remedial actions for all known sites, plus suggesting future research and study. In developing these recommendations careful consideration was given to the psychological and economic impact of the dioxin problem and proposed solutions on affected Missouri citizens.

The report includes additional background materials and acknowledgement of all experts who have been heard. These are attached as appendices. Transcripts of testimony heard and of proceedings of the Task Force meetings are available through the office of the Department of Natural Resources.

The Task Force wishes to thank the Directors of the Department of Natural Resources (DNR) and the Division of Health (DOH) and their staff members for their excellent cooperation in obtaining and providing literature, for arranging for witnesses whom the Task Force desired to hear, and for providing necessary staff work.

Based on our evaluation of all the testimony and data received, the Task Force recommends the following: (For explanation and amplification of these recommendations see the Section entitled Rationale for Recommendations).

RECOMMENDATIONS

I. The Task Force recommends that secure central storage of Missouri's soil contaminated with dioxin exceeding acceptable limits should be provided until proven technology is available to assure a comprehensive and permanent solution to dioxin contamination with minimum risk to public health and the environment.

II. The Task Force recommends that health studies on Missouri citizens potentially exposed to dioxin in residential, manufacturing or other occupational settings should be continued and expanded to assess the long-term public health effects due to dioxin.

III. The Task Force recommends that the Missouri Dioxin Strategy for secure storage of dioxin contaminated soils and for assessment of health effects, as stated in this report, be adopted and thereafter periodically updated. The Strategy includes the following components and provisions:

A. The Missouri Dioxin Strategy must include all sites regardless of CERCLA status.

B. High priority should be given to development and publication of an expedited schedule for sampling and analysis at all suspected sites, and for extensive grid sampling at known sites.

C. High priority should be given to the siting for and construction of a central storage facility and interim storage as required.

D. The central storage facility should be utilized only for dioxin contaminated solids.

E. A primary aim should be the reconstruction and reinhabitation of all sites.

F. The state should establish criteria and follow a uniform policy regarding residents and owners of dioxin sites.

G. The experience gained at Seveso, Italy, should be utilized to the extent possible.

H. The residual level of dioxin allowed to remain after excavation and decontamination must be specified.

I. The State should begin immediately to communicate the criteria for safe transportation of dioxin contaminated soils on Missouri roads and highways to address public concern.

J. A Missouri Program in Toxicology should be established.

K. An advisory panel, similar in composition to this Task Force, but including two dioxin site resident representatives, should be formed to advise the Director of DNR.

HEALTH RISKS

In order to responsibly assess the possible remedial actions, it is necessary to understand the public health dangers associated with dioxin. For purposes of this report, the health effects of dioxin are classified as acute, chronic and carcinogenic. There is some overlapping of these areas which means that the symptom-complex interrelationships also must be examined. The following is a brief summary of each of these areas:

1. Acute Toxicity. The acute toxicity of relatively large doses of dioxin incident to industrial accidents is well documented. Chloracne appears within several weeks and may persist for many years. It is disfiguring and may produce psychological stress. Liver disease may also be found but is not consistently evident in man. Porphyria cutanea tarda is another condition which may be produced by exposure.

Cell mediated immunity is decreased by dioxin in mice. There is minimal evidence on whether dioxin exposure causes immunosuppression in humans. In a study of 45 children from zone A, the area of highest dioxin concentration, of Seveso, Italy, Pocchiari, et. al. showed in four repeated examinations over the first year following the accident that there were no immunological differences between the exposed children (21 of which had chloracne) and a minimally exposed comparison population.

Dioxin is a potent inducer of aryl hydrocarbon hydroxylase (AHH) and at least a dozen other enzymes in animals.

2. Chronic Effects. The most obvious chronic effect is persistent chloracne. Other effects such as porphyria cutanea tarda, liver dysfunction, and functional changes in kidneys, pancreas, blood and lipid metabolism, have been reported following accidental exposure to dioxin and related compounds but it is difficult to determine whether the signs and symptoms observed were due to dioxin or other chemicals involved.

Neuropathologic findings including nerve conduction defects and demyelinization of nerves, particularly in the lower limbs, have been demonstrated. Numerous neuropsychiatric symptoms such as fatigue, depression and headache have been described, but cause and effect relationships with dioxin are difficult to validate with present methods.

Reproductive effects of dioxin such as fetotoxicity and teratogenesis have been shown in a number of animal species. However, human epidemiologic studies in Germany, the United States, Australia, and at Seveso have shown no apparent derangements of gestation, no fetal loss, no gross malformations and no cytogenetic abnormalities. A study in Oregon alleging an increase in abortions among exposed women was subsequently declared valueless by reviewers from Oregon State University and from Australia, New Zealand and the United States government. A North Vietnamese study alleging increases in birth defects in the children of exposed Vietnamese soldiers cannot be evaluated because the study itself is not available.

3. Carcinogenesis. Probably the most important and yet the least understood possible effect of dioxin is carcinogenicity. It is generally agreed that dioxin is an inducer of cancer in rats and mice. Therefore, it has a potential for causing cancer in humans. It is unnecessary, for the purposes of this report, to decide whether dioxin might be a cancer initiator, a cancer promoter, or whether its action is exerted through enzyme or cellular immunity changes.

Two methodological problems in the assessment of the possible carcinogenic action of dioxin are the long "latent period" of most cancers and the small numbers of exposed individuals from industrial accidents that occurred more than twenty years ago.

Studies in Sweden and testimony before the U.S. Congress by the Director of the NIOSH Division of Surveillance, Hazard Evaluations, and Field Studies have indicated a higher risk of soft tissue sarcomas among those workers exposed to dioxin and the phenoxy acids. The question of an increase in cancer rates among Vietnamese is not fully resolved. A study of participants in "Operation Ranch Hand" of the Air Force has not implicated dioxin in carcinogenesis nor have the studies in Finland and New Zealand. Definitive results from the Air Force study cannot be expected until a sufficient period of time has passed to rule out or implicate dioxin as a carcinogen among those exposed to "Agent Orange".

An EPA panel of experts in July 1983 prepared a draft report after considering all available evidence which stated dioxin must be considered a probable human carcinogen.

4. Dioxin Symptom-Complex Interrelationships. It is customary, from the clinical point of view, to describe a number of symptoms related to an infection or an environmental exposure as a symptom-complex with various stages of the disease. In the case of dioxin exposure there are those who would insist that chloracne is the "stage one" or hallmark of all subsequent chronic or carcinogenic effects and that without chloracne, no subsequent effects would be expected. However, considering the various routes of exposure, the degree of exposure, and the shortness of the time since such exposures occurred, it is impossible to state unequivocally that chloracne is a prerequisite for dioxin intoxication.

There is some published evidence that soft tissue sarcomas may occur in persons exposed to dioxin who had no preceding chloracne. The question of other adverse health effects such as nerve conduction defects and reproductive problems occurring without prior chloracne is not resolved. However, there is certainly enough concern about this issue to warrant continued investigation. An interrelated problem requiring further research is the reported background adipose tissue levels of dioxin among the "normal" population which varies from 0.007 to 0.020 ppb. These background levels have been established in studies by the U. S. Air Force, Veterans Administration, and Canadian government. Therefore, it is possible that there are other sources of dioxin in the environment. Such sources may include incineration and chemical derivatives of the trichlorophenol synthesis such as hexachlorophene and 2,4,5-T. The possible sources are not yet well defined.

MISSOURI HUMAN HEALTH RISK ASSESSMENT

The problem of dioxin in Missouri is that the potential for exposure of the affected population consists of protracted contact with soils contaminated by spraying with a mixture of oil and dioxin more than ten years ago. The only evidence presented to the Task Force of any acute human effects occurred at a horse arena where the level of dioxin was measured at 32,000 ppb - a level much higher than that measured at any of the residential sites. The fact that horses, pets, and birds died immediately following the road and horse arena spraying may be due either to species differences in sensitivity to dioxin in these animals, or to a high dosage and close contact with the sprayed material, the soil and the dust, or to other unknown contaminants in the sprayed material.

For most Missourians the likely exposure has been limited to dioxin in the soil, the dust emanating from the soil, and the erosion and mobilization of the soil as sediment in surface waters and the resulting contaminated fish. There is tight binding of dioxin to soil particles and it has low solubility and vapor pressure which reduces its solubilization and percolation into ground waters or vaporization into the atmosphere. Therefore, the risk assessment in Missouri is confined largely to the possible chronic and carcinogenic effect of low dosage exposure to dioxin in soil over a period of many years.

Bioaccumulation of dioxin in fish from contaminated streams has been shown in Missouri. It is believed that there is limited uptake into food plants. Therefore, the human food chain may be affected.

It must be cautioned that a complete assessment of the health risk at this time is not possible for the following reasons:

1. Recent health studies undertaken by the Missouri Division of Health and NIOSH are not complete. These reports when submitted must be carefully examined.

2. Further study is needed concerning the rate of absorption of dioxin from contaminated soils. Bioavailability of dioxin may be limited by soil binding which appears to increase over time.

3. The soil sampling procedures used by EPA to date have primarily been designed to detect contaminated areas and not to evaluate habitant exposure.

4. Much of the available information of health effects has come from exposure at industrial accidents where the level of the actual exposure was largely unknown and the route of exposure was quite different from soil contact.

5. The knowledge of background levels of dioxins in humans is inadequate at present.

6. The actual past dioxin exposure histories of Missouri residents are only gross estimates. Exact determination of an individual's exposure to dioxin is extremely complex and currently can only be estimated. In the future

it is expected that tests to measure tissue and blood levels of dioxin will be available and make human risk assessment more precise and simpler. For the present, using worst case assumptions, experts from the Centers for Disease Control have decided that a concentration of 1 part per billion in composite soil samples should be considered the upper limit of safe exposure in residential settings. It is important to note that children would have the most exposure to soil and dirt by ingestion and would probably receive the greatest dose per body weight. In adults with less soil contact the risk could be significantly less. Continuous and extended exposure to this soil level would be expected to increase a person's risk of cancer by one in one million in six to seven years. A review of this standard is being conducted by the Centers for Disease Control. A tentatively proposed maximum dioxin level in water is at the parts per quintillion (10 raised to the minus eighteenth power) level, based on the biologic concentrating capacity of aquatic organisms which may be found in the human food chain. It should be added that such levels cannot yet be analytically determined.

For the present, therefore, we have no choice but to use the limit of 1 ppb of dioxin in residential soils as the upper limit of allowable soil concentration, with the resulting stream sediment, water contamination and food chain content being some smaller concentration.

HEALTH CONCLUSIONS

The Task Force reaches the following conclusions on the health effects of dioxin exposure:

1. Dioxin is acutely and chronically toxic to humans as demonstrated in accidental large, but unknown dosage exposures.

2. Dioxin may be absorbed in the human by skin contact, by inhalation, and by ingestion.

3. In Missouri, the potential dosage exposure is complicated by the tight soil binding proclivity of the compound, the long-term (more than 10 years) exposure to soil levels ranging from one to more than one thousand parts per billion, and the variations in exposure to the contaminated soils due to differences in age, occupation, and living environment.

4. The review group convened in July 1983 by EPA and the Director of the Division of Surveillance, Hazard Evaluation, and Field Studies of NIOSH of the USPHS have characterized dioxin as a probable carcinogen.

5. Present risk assessment procedures based upon the reproductive and carcinogenic effect appear to suggest a maximum safe level of 1 ppb in residential soils of Missouri. Levels in water and human food chain vegetation, mammals and fish may be required. CDC and EPA are encouraged to establish standards for allowable levels of dioxin as soon as possible.

6. Little is presently known about: adipose tissue levels of dioxin in "normal" or unexposed individuals in comparison to those with known exposure; the absorption and metabolism of dioxin and related compounds; and the long-term effects of various dosages, entry into the human, and the biological availability of the compound in the various soil, water and air conditions in which dioxin is now being found.

7. Human contact and exposure to contaminated soil should be minimized.

8. Sufficient funding should be provided for appropriate follow-up studies to be conducted on the exposed populations.

9. Careful consideration should be given to dealing with the emotional stress of living in and near contaminated areas. Effective methods should be developed to consistently advise and counsel residents of contaminated areas.

10. There should be continuation of health education for the general public about dioxin. There should be continual review of all research concerning dioxin. Uncertainty about the health effects of exposure to dioxin has caused fear and psychological and emotional stress. Health education techniques, including the dioxin hotline, are essential to the well being and rational activity of our citizens.

11. There is no human health benefit attributable to dioxin which is usually produced as an unwanted by-product in chemical manufacturing processes.

A primary concern of the Task Force was the determination whether the dioxin contamination of the soils of various Missouri communities since 1970-71 required only continued surveillance of the health of the individuals exposed or whether the past decade of such soil-dioxin exposure had been, and continues to represent, a sufficient health and environmental hazard to require remedial action. Weighing the testimony given, and other information made available to us, it is the conclusion of the Task Force that the dioxin contaminated soil in Missouri does constitute a hazard to the health of citizens exposed to such contaminated soil. The degree of the hazard is not presently determinable; therefore, deliberate, prudent remedial action should be taken to eliminate future exposure and health studies should be continued and expanded.

RATIONALE FOR RECOMMENDATIONS

I. The Task Force recommends that secure central storage of Missouri's soil contaminated with dioxin exceeding acceptable limits should be provided until proven technology is available to assure a comprehensive and permanent solution to dioxin contamination with minimum risk to public health and the environment.

After considering all of the scientific literature and testimony provided, the Task Force concludes that a permanent solution to the dioxin contamination in Missouri cannot be recommended at this time because there is no proven technology for the safe destruction of dioxin in soils. Secure storage should be provided until destruction technology becomes available.

Secure storage will require about five years to accomplish. Based on the Seveso experience with excavation and storage, costs could be about $70.00 per cubic yard. However, after considering all available information on remedial technologies, health effects, and impact on Missouri and its citizens, the Task Force believes that this action must now be taken.

In the Task Force's interim report it was concluded that no proven technology then existed for the destruction of dioxin. (See Chapter 6 of that report for an assessment of available technologies.) The Task Force now concludes that adequately proven technologies for the destruction of dioxin in soils will not be available for several years.

Incineration is probably the nearest to being a proven technology, but it appears that perhaps five years of laboratory and EPA permitted pilot studies would be required before construction of an incinerator could begin. Also, it is not clear that an exemption could be obtained from the EPA requirement that residues from destruction of acutely hazardous wastes must be stored in a facility meeting the same requirements as the material before destruction. Since the incineration of soil would not drastically change its volume, a storage facility, as recommended above, might still be required. Incineration, then, is not a short term option, and all other technologies appear less likely to be applicable within the next decade.

The Task Force also concludes that technologies which require extensive processing, such as solvent extraction, are inappropriate at this time. These approaches create more waste than originally existed, are inherently expensive, and present considerable risk of environmental release and human exposure.

II. The Task Force recommends that health studies on Missouri citizens potentially exposed to dioxin in residential, manufacturing, or other occupational settings should be continued and expanded to assess the long-term public health effects due to dioxin.

The Task Force recommends that health studies should be expanded to include all identifiable Missouri citizens who potentially have been directly exposed to dioxin contaminated materials. In addition, Missouri should participate in studies similar to those recently reported on the dioxin content of human adipose tissue to assist in determining background levels due to other exposures.

III. The Task Force recommends that the Missouri Dioxin Strategy for secure storage of dioxin contaminated soils and for assessment of health effects, as stated in this report, be adopted, and thereafter periodically updated.

The widespread distribution of dioxin in Missouri is an unfortunate reality which has presented serious health concerns and a serious social and economic problem to the State and to many Missouri citizens. Lacking a technology for destruction of dioxin contaminated soil, a definite end to potential exposure of citizens and the environment should be provided by secure storage which would permit return of the affected areas to productive use.

Of particular concern to the Task Force is the public perception of inactivity followed by abrupt actions. Therefore, it is recommended that this strategy for secure central storage, as herein outlined and recommended, should be adopted by the DNR, DOH and the EPA immediately. To the extent possible, the State should assume leadership in the implementation of this strategy, even if some additional costs are incurred by the State. The public must know that a single coordinated strategy is being followed to achieve an attainable resolution to contamination in Missouri, and that sufficient funds are available to implement it. To address the concerns of Missouri citizens, implementation of this strategy should include an opportunity for public comment and public hearings. Once adopted, this strategy should be periodically updated to keep Missouri citizens informed and to permit their comment on actions to be taken.

The Task Force believes that specific responsibility should be assigned the Director of DNR to assure that priority is maintained on this problem until closure of the secure storage facility. A system for information release should also be established so Missouri speaks with one voice to residents and owners of dioxin sites and to the public. Such information release might be accomplished by an expanded Dioxin Update and periodic press releases. Regular listing of the implementation status at each site should be included. To the extent possible, information from State agencies should be supplemented with sufficient explanation to permit the public to view the information in the context of this Strategy. Information released or published by EPA, Centers for Disease Control (CDC), Veterans Administration (VA), National Institute for Occupational Safety and Health (NIOSH), or others should be summarized, evaluated, and commented upon to help the public to assess its impact on the Missouri Dioxin Strategy.

It is the opinion of the Task Force that the State of Missouri has a public image as the dioxin center of the USA. That problem should be addressed and solved, even if the solution requires the expenditure of some funds currently not available. Otherwise, that image will continue to disrupt the lives of its citizens and plague the economic well being of the State. A decisive plan and responsible action will clearly demonstrate to the public that Missouri is willing to make and execute the necessary decisions to ensure the health and well-being of her citizens and to provide a good environment in which to live. It is believed that this was the experience of the Seveso Authority, whose representatives presented to the Task Force a description of their response. Some of their decisions may prove to be inadequate or excessive, but the Seveso Authority took action according to a publicly stated plan and subsequently reinhabited the area, permitting life to go on until an ultimate answer can be found.

The extremely toxic properties and potential health effects of dioxin have caused an enormous effort to be mounted to rid the environment of this hazardous substance. While this high level of concern is certainly justifiable, dioxin also has several properties which greatly reduce exposure to humans and migration in the environment. These properties include its extremely low solubility in water, extremely low volatility, and tight binding to soils. While dioxin is extremely toxic, dioxin as it exists in Missouri soil may not be as serious a problem as other contamination by very toxic and carcinogenic hazardous wastes. Our zeal to rid the State of dioxin should not deplete financial and human resources to the exclusion of the other very important hazardous waste problems in Missouri.

In summary, the Task Force concludes that an orderly, planned removal of dioxin contaminated soil to a secure storage facility best serves the interests of Missouri and its citizens. Recognizing the potential effects of dioxin, it seems prudent to take decisive, but not panic-driven actions to eliminate potential exposure and control the spread of dioxin in Missouri. A planned approach will require several years to implement and will require delay at some sites relative to others. Some sites will require short term remedial actions due to relative risks of exposure or probable spread of contamination. Most other sites should be left intact until removal and storage can be accomplished. For a few sites it seems possible that the health and environmental risks may be eliminated without excavation. These sites might be left intact with only long term surveillance and maintenance.

A. The Missouri Dioxin Strategy must include all sites regardless of CERCLA status.

The majority of the confirmed sites in Missouri contain contaminated soil which can be treated in a similar manner. In the Task Force's opinion, these sites should be handled as one problem under the Comprehensive Emergency Response, Compensation, and Liability Act (CERCLA). If this is not possible under Federal law, Missouri should nevertheless follow a comprehensive strategy for all sites.

Under the present CERCLA Law all hazardous waste sites undergo a site evaluation and ranking procedure. Based on a large number of parameters, each site is assigned an overall priority number which determines if that site qualifies for remedial monies under CERCLA. Currently only 6 of 33 dioxin sites in Missouri qualify for these funds, which are being administered on a site by site basis.

To remedy this situation, the State has requested that EPA combine the 33 sites for consideration as a single CERCLA site and currently is conducting negotiations with EPA to that end. The Missouri dioxin problem is unique in that while the sites are not contiguous, they are linked together because of the same type of contamination, namely dioxin in soil, the common origin of much of the material, and uniformity of the method of disposal. Individual listing of the sites causes extreme duplication of effort within a number of state agencies in every facet of handling of the sites, including health studies, remedial actions, and attempts at cost recovery. Feasibility studies being done for EPA on several of the CERCLA sites are identifying the same range of solutions. Considering each of the sites separately adversely affects the type of solution selected and the cost of that solution. Since in Missouri the total cost of transporting materials off-site appears to be a small fraction of the total cost of remedial actions, a policy of treating all non-contiguous sites separately is not cost effective or logical. Therefore, it is recommended that the State continue to make every effort to have the 33 sites ranked as a single CERCLA site.

Should this primary course of action not be possible, the state of Missouri should still follow a uniform strategy to fully address the dioxin problem. The residents of non-CERCLA sites are no less concerned with the potential health problems, loss of property use, land values, and the overall psychological effects of the problem than those on sites which have higher CERCLA risk assessment point totals. If federal law cannot address their plight, the state of Missouri must provide the necessary uniformity of action.

B. High priority should be given to development and publication of an expedited schedule for sampling and analysis at all suspected sites, and for extensive grid sampling at known sites.

It is recommended that adequate sampling and analytical capabilities should be established or contracted by the State to provide this critically needed information as soon as possible.

An expedited timetable for comprehensive sampling of all sites, and prompt analysis of samples taken, should be developed to define the total problem in Missouri. It is recommended that the State should supplement its own resources with contract sampling and analyses to provide timely response. It is also recommended that a careful study by industrial hygiene experts should be made to determine the protective equipment appropriate to the sampling activity. Workers should be protected from expected danger, but residents should not be unnecessarily alarmed by overemphasis on worker protection.

C. High priority should be given to the siting for and construction of a central storage facility and interim storage as required.

A timetable for selection and construction of the facility and estimates of the period of time required to accomplish secure storage should be given at the earliest possible date.

The Task Force recommends that several potential storage sites should be selected and critically evaluated immediately. The criteria for the facility should include complete encapsulation of the dioxin contaminated soils and solid debris; collection, monitoring and treatment of water from the facility prior to release to the environment; prevention of rupture of the facility due to thermal expansion and contraction or moderate earthquake activity; and separation from the existing soil and ground water system. Criteria for the site should include State ownership; low land usage but with parks and wilderness areas excluded from consideration; accessibility for soil transportation; minimal risk of public exposure; and utility of the site following facility closure.

The Task Force specifically recommends that Times Beach should be included in the evaluation of potential sites. In spite of obvious concerns about flooding, Times Beach has several advantages as a location for a well constructed facility. It is estimated that about ninety percent of Missouri's dioxin contaminated soil is located in eastern Missouri with about sixty percent being in the Times Beach roadways. Potential for exposure and potential for spread to the environment and total cost could all be minimized by locating the storage facility on this site.

If about sixty acres of Times Beach were filled with clean soil to above maximum flood level, an above ground facility, similar to those built at Seveso, could be constructed to safely collect and control water from the facility. The construction of a levee, which may be required to permit excavation and removal of soil to another site, would provide additional protection for the facility. Following closure and replanting, the area should be made available for public use.

D. The central storage facility should be utilized only for dioxin contaminated solids.

It is recommended that alternate technologies, such as incineration, should be utilized for the small amounts of existing liquid wastes containing dioxin. The central storage facility must be constructed exclusively for the containment and control of dioxin contaminated soils and associated solid debris. The Task Force concludes that existing or proposed hazardous waste landfills are not acceptable alternatives.

The high probability that ultimate destruction of dioxin contaminated wastes may be required and become feasible in the future dictates that only solid dioxin wastes should be included in this facility. Non-contaminated solids, such as houses, trailers and trees, should not be stored in the dioxin facility simply because they are located on a dioxin site.

E. A primary aim should be the reconstruction and reinhabitation of all sites.

Decisions should be made for each site based on total assessment of risks of the spread of dioxin in the environment and risks to the health of residents and the public. Special efforts should be made to maintain the integrity of affected communities, and minimize the financial burden.

The Task Force recommends that the preservation of neighborhoods and communities should remain a high priority. The Missouri Dioxin Strategy must recognize that disruption of residents' lives has already occurred, with accompanying emotional stress, and that actions taken should be sensitive to residents' concerns. Property purchases do not solve the problem.

F. The state should establish criteria and follow a uniform policy regarding residents and owners of dioxin sites.

Included should be criteria for temporary relocation to reduce exposure, temporary relocation during excavation and reconstruction, level of reconstruction, replacement of personal property, title clearance on reconstructed sites, and maintenance and control of sites stabilized and left intact.

To build and maintain public confidence in the Missouri Dioxin Strategy, a uniform policy must be communicated and followed. While it is recognized that different actions will be required at different sites, and that all residents' concerns and expectations cannot be universally satisfied, actions that are taken must be administered fairly and equitably. In particular, during relocation of residents, adequate consideration must be given to protecting family structure and minimizing psychological and economic impact.

G. The experience gained at Seveso, Italy, should be utilized to the extent possible.

Much information is available on worker protection, sampling techniques and construction engineering data. This should be utilized to minimize response time and costs in Missouri.

The Task Force was impressed by the efforts of the Lombardi Government and its agent, the Seveso Authority, in addressing the problem at Seveso. A great deal of information was generated and should be utilized by the State to the extent possible. One of the problems they encountered was the delay in obtaining analyses during excavation. It is recommended that the State should address that problem before beginning excavation since it strongly affects both the timeliness and cost of excavation.

The Task Force recommends that a summary of the Italian health studies should be provided to Missouri citizens, along with their findings on dust monitoring and other aspects of excavation and storage.

H. The residual level of dioxin allowed to remain after excavation and decontamination must be specified.

The Task Force recommends that CDC develop residual levels of clean up which will permit return of residential and agricultural properties to unrestricted land use as soon as possible. In addition, certain other residual levels, which may be site specific, should be developed for restricted use in areas such as commercial and industrial settings. Contaminated soil, excavation and processing must take into account the health and safety of workers and the local population.

The Task Force concludes that properties should be returned to unrestricted use, and removed from the dioxin registry, at the earliest possible date. To accomplish this, acceptable residual levels for clean up must be established.

I. The State should begin immediately to communicate the criteria for safe transportation of dioxin contaminated soils on Missouri roads and highways to address public concerns.

A mechanism must be developed for educating and reassuring residents and the public near any proposed route over which transportation of dioxin contaminated soil will occur. The concerns of these citizens are no less important than those of residents, workers, etc. The Task Force believes that state-of-the-art technology can provide all of the needed protection and that a format must be found for conveying this information.

J. A Missouri Program in Toxicology should be established.

It must be recognized that dioxin is by no means the last toxic material which may threaten the health and well being of Missouri citizens. To assist in final decisions regarding dioxin destruction and to provide a system for informed and rational future responses to toxic substances, a State Program in Toxicology should be established. That program should include an efficient system for gathering information, state-of-the-art analytical development capabilities, and appropriate animal toxicological research facilities.

The Task Force recognizes that a program in toxicology cannot be implemented to provide immediate response to the present dioxin problem. However, once secure storage of dioxin contaminated soils is provided, many dioxin questions will still need to be addressed as the ultimate destruction of dioxin is considered. This program will assist in the continuing evaluation of dioxin and will provide for an early response to future toxic waste issues. The Task Force strongly recommends that such a program should be established as a State facility, utilizing, to the extent possible, the capabilities that already exist in the universities and industries in Missouri through cooperative programs. The recently enacted hazardous waste legislation will have limited success until it is possible to define and quantitate compounds and define their degree of hazard to human health through toxicological testing and research.

K. An advisory panel, similar in composition to this Task Force, but including two dioxin site resident representatives, should be formed to advise the Director of DNR.

This panel should exist only until secure storage site closure is accomplished. It should make recommendations concerning final remedial actions and long term health studies. The Task Force believes that such an advisory panel with citizen representatives from academia, public groups, industry and dioxin site residents could provide valuable public input and oversight of the implementation of the Missouri Dioxin Strategy.

SITE SPECIFIC RECOMMENDATIONS AND PRIORITIES

Recommendations on remedial actions to be taken at each site and the relative site priorities are based on the information presently available, and should be altered as new facts, particularly from more intensive sampling, become available. Recommendations are based on the assumption that the Missouri Dioxin Strategy for secure storage will be adopted and that necessary funding will be provided to implement the plan under CERCLA or by the State.

In developing recommendations and priorities, the following factors were given primary consideration by the Task Force: overall risk to residents, workers and the environment; exposure risks to residents (especially children) and workers; potential for erosion and dusting; maintenance of neighborhoods and property values; and long term effects on Missouri and its citizens.

Due to the similarity of circumstances at some sites, and the widely varying circumstances at others, the Task Force chose to assign priorities and make recommendations based on groups of similar sites. (Any future confirmed sites must be separately evaluated and acted upon.)

Our recommendations are as follows:

Group I: Sites where short term excavation and interim storage of excavated soils should be considered to prevent exposure and restore the neighborhood.

Sontag Road
Quail Run

It is recommended that extensive sampling, temporary relocation of residents, excavation of soil with removal to an off-site interim storage facility, reconstruction and reinhabitation should be planned and implemented as soon as possible.

Group II: Sites where short term stabilization actions to prevent exposure or erosion should be taken, with the site remaining intact until secure storage can be accomplished.

Minker
Stout
Saddle and Spur Club
Cashell Residence
Ruth Sullins Property
Romaine Creek

It is recommended that short term actions should be taken to determine the potential for exposure and erosion, then provide temporary protection, possibly including off-site storage, until permanent removal, secure storage, reconstruction and inhabitation can be accomplished. (See recommendations on Minker-Stout in the Interim Report of the Task Force.)

Group III: Sites which should remain intact until secure storage can be accomplished.

- Spring River
- Denney Farm
- Shenandoah Stables
- Bliss Farm Road
- Wall Property and Piazza Road
- Bubbling Spring Arena
- Timberline Stables
- Erwin Farm
- Rusha Farm
- Times Beach
- Methodist Church
- Bliss Oil Frontenac
- Mid-America Arena
- Sand Cut Road
- Baxter Gardens

It is recommended that these sites should be continuously assessed as new sampling information becomes available.

Group IV: Sites which should be assessed for potential exposure, dusting, erosion and the presence of utilities in affected areas. Depending on that assessment, the areas should be paved and excavation and use controlled, or they should be included in Group III for excavation and secure storage.

- Southern Cross Lumber Company
- Hamill Transfer Company
- Overnite Transfer, Inc.
- Jones Truck Lines

Group V: Sites where other remedial actions are in progress or being negotiated.

- Syntex Verona
- Syntex Springfield
- Neosho Digester, Trench, Tank, Spill Area and Wastewater School
- Bill Ray Farm

It is recommended that the current negotiations and remedial actions should continue with the State providing secure storage, as required, to expedite resolution.

Group VI: Sites where sufficient data is not available for recommendation.

- Bull Moose Tube Company
- Community Christian Church

RECOMMENDATIONS FOR FURTHER RESEARCH

The Task Force recommends that the following scientific studies should be done to expand the available data base on dioxin with emphasis on ultimate disposal solutions:

1. Physical properties of dioxin in water and other solvents should be determined.
2. The binding mechanism of dioxin to a variety of soils, and the soil water distribution coefficients should be determined.
3. The method(s) by which dioxin moves in the environment should be determined and quantified.
4. The natural decay rate of dioxin in water and a variety of soils should be determined.
5. The temperature-vapor pressure relationship for soil bound dioxin should be quantified, and the ambient rate of volatilization from soil determined.
6. Parameters for the volatilization of dioxin bound to soil and for incineration of volatilized dioxin should be determined.
7. The ash from incineration of dioxin bound to soil should be analyzed to determine if the resulting ash can be delisted under RCR'.
8. Continuing work should be done on insitu treatment of dioxin contaminated soils (e.g. chemical destruction).
9. Microbial degradation studies to find or develop an organism which can safely and economically degrade dioxin under field conditions should be continued.
10. Acute and long term health studies in multiple species to clarify the:
    a. Absorption of dioxin from soils and other media and from the food chain.
    b. The metabolism of dioxin.
    c. The toxicology and carcinogenic potential of a prolonged period of low dosage of dioxin.
11. The determination of tissue levels of dioxin to include: the normal or "base line" levels of dioxin in the tissue of "unexposed" humans; the possible low dosage cumulative tissue concentrations over time; the change in such tissue levels over time in highly exposed individuals; and the correlation of blood and tissue levels of dioxin with different types of exposure.

12. Continuation and expansion of the current epidemiologic and clinical studies of the individuals exposed to dioxin in industrial accidents; exposed through protracted soil contact such as in Missouri; and in groups otherwise exposed in the past and at present to other chemical product derivatives of trichlorophenol, possibly contaminated with dioxin.

We, as members of the Governor's Dioxin Task Force, do hereby approve the Task Force report this 31st day of October, 1983.

GLOSSARY OF MEDICAL TERMS

Acute: Having a short or relatively severe course.

Adipose tissue: Fatty tissue.

Aryl hydrocarbon hydroxylase (AHH): A normally occurring liver enzyme, the function of which includes the metabolism or break-down of borth natural and poisonous substances in the body. In certain laboratory animals, this enzyme has changed some substances into carcinogens.

Carcinogenic: Producing cancer.

Cell mediated immunity: Specific acquired immunity in which the role of small white blood cells called T-lymphocytes is predominant; it includes certain aspects of resistance to bacterial and viral infections, to cancer, and to organ transplants, and has a role in certain allergies.

Chloracne: Skin eruptions that are somewhat similar to but sometimes more severe than teenage acne, but unlike teenage acne are due to exposure to organic compounds containing chlorine or other related chemicals.

Chronic: Persisting over a long period of time.

Cytogenesis: The formation and development of cells.

Demyelinization: To remove the myelin which covers some nerve fibers. The myelin is a white fatty substance which forms a sheath around certain nerves.

Fetotoxicity: The quality of being poisonous to the fetus.

Immunosuppression: Diminution of the immune response.

Lipid: Any one of a group of complex compounds which include fats, oils, fatty acids, waxes, etc.

Neuropathologic: Pertaining to diseases of the nervous system.

Neuropsychiatric: Pertaining to diseases that may have both a neurologic and psychiatric basis.

Porphyria cutanea tarda: A disease in which the metabolism of porphyrins (a chemical produced in the liver) is disturbed resulting in chronic skin lesions and an enlarged liver.

Soft-tissue sarcomas: A type of cancer found in muscle, fat, nerve, or connective tissue.

Synthesis: The formation of a complex chemical compound by the combining of two or more simple sompounds.

Teratogenesis: The production of physical defects in the developing fetus in utero.

EXECUTIVE ORDER
83-5

WHEREAS, extensive laboratory testing has confirmed the presence of dioxin at several locations in Missouri; and,

WHEREAS, dioxin is a potentially deadly chemical which threatens the health and safety of thousands of Missourians,

NOW, THEREFORE, I, CHRISTOPHER S. BOND, GOVERNOR OF THE STATE OF MISSOURI, by virtue of the authority vested in me by the Constitution and laws of Missouri, hereby establish the Governor's Task Force on Dioxin (hereinafter the "Task Force") which shall be composed of such residents of Missouri as from time to time may be appointed by the Governor. The Task Force shall include representatives of Missouri higher education institutions and Missouri companies which have expertise regarding hazardous wastes, as well as concerned citizens. The Chairman of the Task Force shall be designated by the Governor.

The purposes of the Task Force shall be as follows:

1. To examine and evaluate all known methods, processes and technologies for the destruction and containment of dioxin, particularly with respect to dioxin as it exists as a contaminant in soil and stream sediment at various locations in Missouri;

2. To examine and evaluate the public health dangers associated with dioxin, particularly with respect to dioxin as it exists as a contaminant in soil and stream sediment at various locations in Missouri;

3. To prepare and present, not later than June 1, 1983, an interim report which, *inter alia*, provides specific recommendations for solving those public health and environmental problems occurring in Times Beach, Missouri which are the result of dioxin contamination exacerbated by widespread flooding; and

4. To prepare and present, as soon as practicable but not later than October 1, 1983, a final report which includes the evaluations set forth in paragraphs 1 and 2 above, and which recommends a practical and effective plan of action for implementing comprehensive and permanent solutions to the public health and environmental problems caused by dioxin contamination in Missouri.

The Director of the Department of Natural Resources and the Director of the Division of Health shall make available such staff and support resources as are needed by the Task Force in the course of its deliberations. All meetings of the Task Force shall be open to the public, and a record shall be kept of all Task Force proceedings.

EXECUTIVE ORDER
83-5
Page 2

Members of the Task Force shall receive no compensation for their services, but shall be reimbursed from funds provided through the Department of Natural Resources for their reasonable and necessary expenses. The Task Force may contract for the services of such consultants and experts as it deems necessary and shall pay for such services from funds provided through the Department of Natural Resources or the Division of Health.

The Task Force shall meet at the call of the Chairman, or at the call of the Governor or his designate, and shall dissolve upon the issuance of its final report, unless extended by subsequent Executive Order.

IN TESTIMONY WHEREOF, I have hereunto
set my hand and caused to be affixed the
Great Seal of the State of Missouri, this
14th day of February, 1983.

Christopher S. Bond
GOVERNOR

ATTEST:

James C Kirkpatrick
SECRETARY OF STATE

EXECUTIVE ORDER

83-13

WHEREAS, the Governor's Task Force on Dioxin was created by Executive Order 83-5 on February 14, 1983; and,

WHEREAS, said Executive Order provided that said Task Force was to prepare and present, as soon as practicable but not later than October 1, 1983, a final report, and that said Task Force was to dissolve upon issuance of said final report, unless extended by subsequent Executive Order; and

WHEREAS, need has arisen for said Task Force to obtain and evaluate additional information prior to preparation and presentation of said final report,

NOW THEREFORE I, CHRISTOPHER S. BOND, GOVERNOR OF THE STATE OF MISSOURI, by virtue of the authority vested in me by the Constitution and laws of Missouri, hereby extend the existence of the Governor's Task Force on Dioxin, as established by Executive Order 83-5 issued on February 14, 1983, until completion of its final report or until November 1, 1983, whichever sooner occurs, unless extended by subsequent Executive Order.

IN TESTIMONY WHEREOF, I have hereunto set my hand and caused to be affixed the Great Seal of the State of Missouri, this 31st day of August, 1983.

Christopher S. Bond
GOVERNOR

ATTEST:

James C. Kirkpatrick
SECRETARY OF STATE

GOVERNOR'S DIOXIN TASK FORCE

The Honorable James A. Finch, Jr.
Judge
Chairman, Governor's Dioxin Task Force

Mr. Dwight Douglas
Douglas, Douglas & Johnson Law Offices

Mr. Ray Forrester
Engineering Manager & Dioxin Project Supt.
Syntex Agribusiness, Inc.

Dr. Perry King
Director, Quality Assurance Chemicals
Mallinkrodt, Inc.

Dr. Robert L. Powell
Assistant Professor of Chemical Engineering
Washington University

Dr. Carl J. Marienfeld
Professor of Family & Community Medicine
Environmental Health Surveillance Program

Environmental Quality Chairperson
League of Women Voters

TASK FORCE STAFF SUPPORT

Department of Natural Resources

Fred Lafser, Director
Ronald Kucera, Deputy Director

Robert Schreiber, Director - Division of Environmental Quality
Linda James, Assistant Director

David Bedan, Director - Waste Management Program
Beth Rice, Environmental Engineer
Dan Tschirgi, Environmental Engineer
Dianne Luebbert, Clerk Steno
Martha Siegel, Clerk Typist

Mary Still, Director - Office of Public Affairs, Division of Management Services
Nancy Guyton, Office of Public Affairs

Department of Social Services

Dr. Robert Hotchkiss, M.D., Director - Division of Health

Dr. Denny Donnell, M.D., MPH, Director - Disease Prevention Section
Dr. Patrick Phillips, DVM, MSPH
Dr. Thomas Satalowich, DVM, MSPH
Jeff Staake, Dioxin Activities Coordinator

Mr. LEVITAS. Thank you very much, Congressman Young, for your additional contribution. Let me just say that I think you are right in that we have got to be diligent about this. Unfortunately, this is one of those areas it seems to me where the public goes back to sleep 2 months after Times Beach is over, and they only wake up when the next ticking time bomb goes off and there is another Times Beach someplace else. And then they go back to sleep again.

Fortunately there are more and more people such as yourself, such as the panel of witnesses we will be hearing this morning, and others, who are beginning to make this an ongoing issue rather than one which comes and goes as do the headlines. But I think until we do that, the enormity of the problem, the number of sites we are talking about, the now estimated $50 billion it is going to take to clean them up, the fact we haven't even identified some of the worse sites much less cleaned up those we already have identified, nor will we by the end of this century, and the tragedy of what happens to the people who are affected by hazardous waste sites, means that if we aren't persistent and if we don't persevere, the task will not be done. I think that would be a terrible indictment of all of us.

Mr. YOUNG. Mr. Chairman, if I might respond to your remarks, we are still wrestling with low-level radioactive uranium mill tailings in my district. A result of the activity of the creation of the atomic bomb. I still have many, many sites throughout my district. And here we are 40 years later and we have no resolving of that question. And it is a serious question to the people of my district and the State of Missouri.

I have got enough for everybody. If you could just spread it around a little bit like Dolly Levi.

Thank you, Mr. Chairman.

Mr. LEVITAS. Thank you. Mr. Shaw?

Mr. SHAW. I would like to add my words of welcome to you, Bob. I am privileged to serve with the gentleman from Missouri as his ranking member on Public Grounds and Buildings. I know of his continuing concern for the problems that his district has had to bear with regard to toxic waste. Unfortunately, we are just beginning to realize at this time the full impact this type of disposal has on the health of communities around the country.

I am sorry that Mr. Young's district has borne such an extraordinary waiting period of not knowing, and of course the potential health damage that this situation has caused. I know of your concern and work in this particular area, and I appreciate your coming before the committee this morning.

Mr. YOUNG. Thank you very much, Mr. Shaw.

Mr. LEVITAS. Mr. Rowland.

Mr. ROWLAND. No questions.

Mr. LEVITAS. Mr. Wise.

Mr. WISE. No questions.

Mr. LEVITAS. Without objection your entire statement will be made part of the record.

Mr. YOUNG. Thank you. Mr. Chairman, this is an important committee to the public health of this country. I am just real pleased that we had the foresight to move ahead in the investigation and oversight on this right from the beginning.

Mr. LEVITAS. Thank you. I appreciate your being here, Bob.

Mr. YOUNG. Thank you very much.

Mr. LEVITAS. Now, we look forward to hearing from a panel of State legislators who are going to share with us their experience. It is not just because I served for 10 years in the Georgia Legislature that I look forward to this testimony. But it is also because I know from experience here as well as the State level that most of the sound answers we get to the problems this Nation faces come from the innovative experience that our States bring to us.

So it is in no way coincidental that we have today as our next panel of witnesses three State legislators who have played a role in this entire matter. I would like to ask the panel of witnesses to come forward.

Also, I note the presence of our colleague Congressman Matsui from California, who is accompanying Hon. Lloyd Connally from the California Assembly. You may come forward, too, if you would, please.

Assemblyman Connally, Representative Joe Hackney of North Carolina, and Representative Dee Long of Minneapolis, MN.

TESTIMONY OF HON. LLOYD G. CONNALLY, CALIFORNIA ASSEMBLYMAN, SACRAMENTO, CA; HON. JOE HACKNEY, NORTH CAROLINA HOUSE OF REPRESENTATIVES, CHAPEL HILL, NC; HON. DEE LONG, MINNESOTA HOUSE OF REPRESENTATIVES, MINNEAPOLIS, MN

Mr. MATSUI. Mr. Chairman, I merely would like to come to just introduce my colleague.

Mr. LEVITAS. Please have a seat, and do so.

Mr. MATSUI. I would just like to introduce my colleague Assemblyman Lloyd Connally from Sacramento. He and I had served in local government, city council, for 5 years. Then I came back to Washington, of course, and then he went to the State capital.

He has been one of the leaders in the whole area of toxic waste disposal in the State of California. He has knowledge of victim compensation legislation that I am sure you are all interested in hearing about. I think his expert testimony today will be very helpful to the committee and the Congress.

I thank the chairman for inviting him, and myself as well.

Mr. LEVITAS. Thank you, Bob. We appreciate your coming here, and look forward to hearing from Mr. Connally as to his experiences in California.

Thank all of you for being here. I think the best way to proceed would be to have each of you make a brief opening presentation, and then we would like to put some additional questions to the panel and to each of you following your own presentation of your experiences in your State.

So why don't we start with Mr. Connally?

Mr. CONNALLY. Mr. Chairman, members, thank you for inviting me. Mr. Levitas, I don't know how you do it, but you started your committee meeting on time. I wish I could take you back to California. We never start on time; so whatever your magic is, it is good magic.

During the last week and a half or so I had occasion to peruse some of the testimony presented to you folks last summer. It is very impressive indeed. You have obviously put in substantial work. You are to be commended. It is a problem not only in California, as I can tell by the testimony, but indeed throughout the whole country.

California started in 1980 on a similar process in terms of evaluating the issue of compensation, and specifically folks who suffer health problems as a result of toxics. And as a result of a hearing process that extended over the better part of a year, we came to eventually two conclusions: One, that indeed there was a significant number of people, difficult to quantify but a large number of people who are exposed to toxics and suffer health effects as a result of that; two, we came to the conclusion that those folks who suffer serious problems—that is, the ones that are really damaged—have fairly effective remedies available now through the common law tort system, particularly in California where we are fairly progressive with regard to our plaintiff law.

However, we found that the smaller injury, the person who was in many instances isolated and suffered damages of a smaller character had no effective remedy. The costs of proving the causal link between the toxics and health problems they were experiencing was inordinately high; one that would not be borne by private attorneys, one that the individual could not pay.

As a result, in September 1981 the California Legislature adopted and the Governor signed a two-tier system of victim compensation recovery. We didn't know it was two tier at the time because the study group term "two tier" hadn't come into existence, but essentially the same thought pattern was there. One, it was designed so that the larger injury person would proceed under the normal tort action in the State. Second, for the person who suffered the smaller isolated case, there would be an administrative remedy through our own local or State superfunding mechanism whereby they could file a claim and seek the damage recovery from the harm that they had suffered.

Specifically, we set aside $2 million a year for that purpose, and we put forward the following system: First, we required that the folks either had to suffer the health effects from a source that they did not know where it originated from. For example, they were exposed to toxics at some point so far in the past that they didn't remember where that exposure point occurred, or it was the proverbial orphan site. In the alternative, they had to go to court and seek a judgment, and get a judgment against a nonpolluter, a nonsource, and then be able to collect that judgment either as a result of insolvency or because the person was no longer in business, or what have you. That was the first condition. The second condition was that they had to prove by the weight of evidence that the health harm they suffered was proximately caused by this exposure to toxics. Those are the two conditions they had to meet in order to come under the jurisdiction of the Superfund in order to file that claim.

Once they met those conditions they could recover up to 100 percent of their medical costs for 3 years, up to 80 percent of the lost salary they incurred up to 3 years, and there was the usual language with regards to double recovery.

This law, with the support of business and industry throughout the State, was enacted. Immediately after its enaction, the State moved aggressively to publicize the law. We sent out 60,000 letters to doctors throughout the State of California, to the bar; notices were required to be posted in hospitals and employers that employed more than 50 people.

We have received literally hundreds of inquiries about this law. Almost 30 inquiries a day come into the board of control in terms of how you file a claim. The bottom line is whether or not this law is working. And the answer to that question is that it is not.

The California experience, the law that I have identified, is so squeaky tight that anything short of calling it a failure would be misleading you. Out of the hundreds of inquiries we have received only two people have filed claims to date. Out of the $2 million setaside for the last 2 years not $1 has been distributed to claimants who filed these claims.

I think there are two reasons for this failure. Hopefully, from our experience here, you will not make the same mistake in the Federal legislation. The first mistake was the requirement for those folks who know what the source is to proceed to get a judgment before they can file a claim. That is, proceed to get a judgment, then be unable to claim it. If they are in a position to proceed to expend the funds required to prove they are in fact suffering from health effects caused by toxic substances, they or their counsel will make a determination at the outset whether or not there is going to be a deep pocket, a source to recover at the other end of that process. So those people don't come to our Superfund for claims.

The second group, these are the folks who don't know the source, the orphaned site group, have to meet the same burden of proof, essentially the same burden of proof that they have to meet in a court of law. That is, they have to prove by the weight of evidence that their health problem was proximately caused by the exposure to the toxic substance. To meet that burden of proof, if they have to do that, they incur the same kinds of costs, the same kind of difficulty and time that the normal process, or normal tort process puts in front of them.

There was in this past year by State Senator Torres, and I joined in this effort, an attempt to change the California law in these two areas so that our victims' comp process would work more effectively. The same groups that had supported the original law, supported the 1981 victims' comp law, opposed the amendments that would make the changes required so that it would work. If there is a lesson here that I could convey to you, it would be that in the fashioning of the Federal remedy you be extremely careful that you do not identify properly that there is not an effective remedy now and then set forward another remedy, as I think we have done in California, that is equally ineffective.

The single most important thing that you can address in that regard is if you move forward with this two-tiered concept in this victims' comp recovery mechanism is to put in some kind of rebuttable assumption so you don't have the same causal proof burden. I find almost unbelievably a consensus vote, one mechanism to provide that presumption. But it ought to be there, some way that is short of the extensive epidemiological studies required to prove that causal connection now, a person who suffers a small injury can make a claim and recover.

Mr. Chairman, that concludes the remarks I have. I did bring with me the California version of the study group. It is a report prepared by our hazardous waste management council, very similar to your report. It was published just this past month. Talks about the California law, the difficulty we are having; makes suggestions for revisions in the California law, which I know will have some applicability to the Federal legislation as well.

Mr. LEVITAS. Thank you very much, Mr. Connally. We would like to have a copy of that.

I have some questions for you, but I think it might be helpful at this time to hear from the other State legislators on the panel.

[The report of the Hazardous Waste Management Council follows:]

HAZARDOUS SUBSTANCE VICTIM COMPENSATION APPLICATION BROCHURE

The State of California has a fund to reimburse any person who has suffered out of pocket medical expenses or lost wages or business income resulting from injuries caused by exposure to releases of hazardous substances. The program is administered by the State Board of Control.

Where to obtain applications or additional information: Contact the Board of Control, 926 J Street, Suite 300, Sacramento, CA 95814-2772. Phone number (916) 324-1342.

Qualifications for filing an application: Applicant must have incurred a medical expense or loss of wages or business income as a result of injury caused by exposure to a hazardous substance which was released in California.

The following conditions must also be met:

(a) The source of the release of the hazardous substance or identity of the party liable for damages in connection with the release or the responsible for the cost of removal of the substance is unknown or cannot with reasonable diligence be determined. This means you must have made some effort to identify the responsible party before filing a claim for compensation with the Board of Control.

(b) The loss was not compensable pursuant to law, including Chapter 6.5 (commencing with Section 25100), because there is no liable party or the judgement could not be satisfied in whole or in part against the party determined to be liable. This means no one was able to identify who caused or was responsible for the release or after identifying the responsible party you were unable to get reimbursement for your damages from them. Lack of recovery could be due to the liable party being insolvent or no longer in existence or cannot be found by reasonable means.

Information that must be submitted when filing a claim under the hazardous substance compensation program:

The law requires that the Board obtain certain information from an applicant before considering the application. This includes the following:

(1) Certification by the claimant of dates and places of residence for five years preceding the date of the claim.

(2) Certification of the medical history of the claimant for the five years preceding the date of claim.

(3) Certification of the alleged physical injury or illness and expense for that injury or illness. The certification must be made by hospitals, physicians or other qualified medical authorities.

(4) Copies of the claimant's federal income tax returns for the three years preceding the incident to establish lost wages or income.

(5) A sworn statement by the claimant attesting to the authenticity of the claim to the best of his or her knowledge.

(6) A full description of the incident supported by appropriate evidence from government agencies of the release of the hazardous substance claimed to be the cause of injury or illness.

Losses compensable under this program:

(a) One hundred percent of uninsured out-of-pocket medical expenses for up to three years from onset of treatment.

(b) Eighty percent of any uninsured actual lost wages or business income caused by injury to the claimant or claimant's property not to exceed fifteen thousand dollars ($15,000.00) per year for three years.

The limits for filing a claim: A claim must be present to the Board under this program within three years of the date of discovery of the loss, or from January 1, 1982, whichever date is later.

Board decisions:

All decisions rendered by the Board under this program shall be in writing and shall be rendered within 90 days of submission of a claim to the Board, unless an extension of time is agreed to in writing by all parties to the claim.

The decision of the Board shall be considered a final agency action for the purposes of judicial review.

Payment of claims: Claims approved by the Board under this program will be paid from the Hazardous Substance Compensation account.

Miscellaneous information:

No compensation or decision by the Board under this program is admissible as evidence of any issue of fact or law in any proceeding brought under any other provision of law.

Compensation for any loss claimed under this program by any other source shall preclude compensation from this program for that identical loss.

Compensation of any loss under this program is subject to the state acquiring by subrogation all rights of the claimant to recover such loss from the party determined to be liable.

The Board has the authority to adopt and revise all rules and regulations necessary to implement the provisions of this program including regulations which specify the proof necessary to establish a loss compensable under this program.

What constitutes a hazardous substance: There are many types of hazardous substances listed under United States Codes and Environmental Protection Agency actions. If you have any questions about the agent which caused your injuries, refer to Section 25316 of the California Health and Safety Code for reference to determining which specific agents are considered hazardous substances under this program.

What the term "hazardous substance" does not include under this program: Refer to Section 25317 of California Health and Safety Code for specifics of agents not considered hazardous substances under this program. In general, they include petroleum, natural gas, liquid gas, or synthetic gas used for fuel or the ash produced by a resource recovery facility using a municipal solid waste stream. Also included is non-toxic, non-flammable, non-corrosive stormwater runoff drained from underground vaults, chambers or manholes into gutters or storm sewers.

What does the term "release" mean: It refers to any spilling, leaking, pumping, pouring, dumping or disposing into the environment.

What the term "release" does not include under this program:

(a) Any release which results in exposure to persons solely within a workplace, with respect to a claim such exposed persons may assert against their employer.

(b) Emissions from engine exhaust of a motor vehicle, rolling stock, aircraft, vessel or pipeline pumping station.

(c) The normal application of fertilizer, plant growth regulants and pesticides.

(d) Release source, by-product or special nuclear material from a nuclear incident. (See California Health & Safety Code Section 25321(c) for specific details.)

Air pollution: Section 25375 of the California Health & Safety Code prohibits the payment of a claim under the Hazardous Substance Compensation Program when that claim is the result of long-term exposure to ambient concentrations of air pollutants, commonly referred to as smog.

Submitting information: Submit only information that is accurate to the best of your knowledge as Section 25373(f) of the Health & Safety Code provides up to a $5,000.00 fine or up to one year imprisonment for knowingly giving or causing to be given false information as part of a claim under this program.

Mr. LEVITAS. Mr. Hackney, why don't we hear from you next, from the State of North Carolina.

Mr. HACKNEY. Thank you, Mr. Chairman. It is a pleasure to be here and to share with you some of our experiences in North Carolina as we grapple with the same problem that is facing my colleagues here.

I guess to describe what is going on in our State one would say that the main battle during the last legislative session was actually over what can be landfilled and what cannot be landfilled. The victim compensation issue was pretty much pushed to the back burner and only got on the calendar along about June or July. Nevertheless I will confine my comments to just that issue; that is, who will pay the damages.

In our State there was a study by our Governor's waste management board in 1981. Thereafter we established a permitting system to meld with RCRA in order to regulate hazardous wastes in our State in a safe manner. That legislation then called for a study, which was done. And that study did recommend adoption of the strict liability concept for hazardous waste occurrences. I have a copy of the study here.

It was found that the law, as my colleague Mr. Connally has so well described, simply is not adequate for the new concepts involved in proving toxic torts—it is often impossible to prove negligence in such a situation—and to define what a hazardous waste handler's duty might be under the negligence system. On the other hand, the strict liability system spreads responsibility for all injuries proximately caused by the "hazardous waste occurrence"—as we have defined it.

Strict liability does not, without some alteration of its pure form, solve the problem Mr. Connally described of proving causation. Sometimes you just can't do it. That is why you do need the Superfunds and governmental assistance. Likewise, strict liability in its purest concepts I suppose does not include the rebuttable presumptions that he mentioned.

I would like to tell you a little about our bill as it was introduced. It has not yet passed. It passed our house and is pending for possible action in our State senate when we meet again next June. As introduced, H.B. 738 contained these provisions:

One. It created a separate system of tort liability for "hazardous waste occurrences," based on strict liability. That is, it placed hazardous wastes, as defined by the Federal laws, in the same category with the ultrahazardous or abnormally dangerous substances that you find in the Restatement of Torts with respect to strict liability.

Two. This strict liability standard applied to generators, transporters, treaters, storers, and disposers, and the bill created a system by which, if the waste were passed on safely to the next person, under the manifest system set up by RCRA—except for the generators—then one was absolved of liability—thereby, we hoped, encouraging safe disposition of the materials.

Defenses allowed were assumption of risk, act of God and act of war, and no others. No punitive damages were allowed. The plaintiff could still elect a negligence theory and pursue that if that was desired. Statutes of limitations—more correctly, under the way our laws are written, called statutes of repose—a 10-year statute of repose in North Carolina was thought to be a bar and that was abolished in the original legislation.

During the committee hearings several objections were raised. Those are noted in my prepared statement, and some of those were credited and some not. There was put in a 30-year statute of repose to change the aforementioned 10-year statute of repose that is applicable in ordinary occurrences in North Carolina.

There was great debate about the subject of contributory negligence, as there is in the literature generally in the strict liability area. It was urged—in fact, the Governor's waste management board report suggested that contributory negligence be a defense. Those of us on the committee felt that that was totally inconsistent with the concept of strict liability and that assumption of a known risk was the proper defense to allow. That view prevailed in committee, and prevailed when the bill passed the House.

What to do about the State's liability was a major problem for us simply because there were no funds set up, as in some other States, for payment for these injuries. So we simply channeled those under the regular Tort Claims Act or State substitute for the workers' compensation.

There was discussion of an additional defense for acts of terrorism and vandalism and whether the strict liability standard, if adopted, ought to be the exclusive remedy.

I have indicated at the bottom of the second page of my statement the form in which the bill did pass the house of representatives. I have several copies of it here as it passed and would be happy to make one of those part of your record.

The emerging legislation we hope will be a part of the puzzle of victim compensation. We do not by any means consider it to be a complete remedy. I certainly support the formation of funds for compensation of victims. South Carolina has done this, and I have a copy of their legislation here if the members of the subcommittee have not seen it.

I do think that victims' compensation in the area of toxic torts requires the adoption of a strict liability standard at a minimum. We must not go into the late eighties and the nineties and expect victims to use the tort system as their principal means of recovery, and not have this strict liability standard. So I would urge the committee to consider some Federal incentive toward States moving their State laws in this direction.

I appreciate the opportunity to come here to tell you what small progress we are making in our State, and I appreciate the efforts of the members of the committee to struggle with this particular problem.

Mr. LEVITAS. Thank you, Representative Hackney, for sharing your experience with us. We, will as I indicated, have some questions in just a moment.

[The statement of Mr. Hackney follows:]

STATEMENT OF REPRESENTATIVE JOE HACKNEY OF NORTH CAROLINA

I have been asked to come to Washington today to tell of our efforts to enact legislation in the State of North Carolina imposing a standard of strict liability for accidents involving hazardous wastes. H.B. 738, after several substantive changes, passed our House of Representatives in July of this year, and is pending for consideration by the Senate in our June, 1984, session of the General Assembly.

H.B. 738 had its genesis in a recomendation by our Governor's Waste Management Board that the system of compensation for injuries in effect, the ordinary negligence system, was not sufficient to protect the public interest. There are many reasons why this is so. North Carolina has not yet adopted comparative negligence, and so any act of contributory negligence, however slight, completely bars any recovery. Secondly, the chances of proving negligence on the part of the hazardous waste handler are always problematical, and especially so in a case where the act of negiligence may have occurred many years previous to the injury.

In addition, current applicable statutes of limitations are simply not intended for present day circumstances. Thus our Governor's Waste Management Board recommended that our State adopt a standard of strict liability for hazardous waste occurrences, and H.B. 738 was introduced.

As introduced, H.B. 738 contained these provisions:

1. It created a separate system of tort liability for "hazardous waste occurrences", based on strict liability.
2. This strict liability standard would apply to generators, transporters, treaters, storers, and disposers.
3. Defenses were assumption of risk, act of God, and act of war.
4. Safe delivery to a hazardous waste facility would guarantee that the generator or transporter would not be liable, thus encouraging disposal in presumed safe depositories.
5. No punitive damages would be allowed.
6. A plaintiff could elect to pursue this remedy for negligence, if desired.
7. The statute of limitations was abolished for actions brought under the strict liability standard.

A series of committee and subcommittee hearings ensued, at which the usual environmental and business lobbies squared off against each other. Committee members heard a series of business objections to the bill:

1. It is unreasonable to have no statute of limitations at all, and industries may not be able to insure against the risk.

2. Not allowing contributory negligence as a defense will allow those at fault to recover. For example, a drunk could drive his automobile into a truck carrying hazardous waste, and still recover from the transporter and the generator.

3. It is unfair for the State to be liable for only $100,000.00 of damages under our Tort Claims Act, and industry to have no cap at all on damages.

4. An additional defense for acts of terrorism and vandalism should be included.

5. If the strict liability standard is adopted, it should be the exclusive remedy.

Our committee substitute bill which finally passed the House attempted to address some of the concerns expressed, but rejected the major ones as groundless:

1. Any statute of limitations would constitute a serious limitation of liability when injuries may become apparent 20-30 years after exposure. Nevertheless, in the committee substitute, there was inserted a 30 year statute of limitations.

2. Contributory negligence is manifestly inconsistent with the concept of strict liability, and its adoption as an available defense in the strict liability bill would make the bill ineffective.

3. The State should be liable in a limited way just as in other tort situations, but with a substituted standard of strict liability.

4. Providing an additional defense for acts of terrorism and vandalism acts as a disincentive to precautions to defend against such acts.

5. The dual remedies should remain, so that a plaintiff who can prove negligence within the applicable limitation period is free to pursue his remedy without the "no punitive damages" limitation included in the strict liability concept.

6. The act was clarified to assure that hazardous materials not yet "waste" were not covered.

7. A defense was established for intentional acts or omissions of third parties not connected to the defendant by an agency or contractual relationship.

Floor amendments which attempted to alter certain of these provisions were all defeated.

The difficulties of molding our traditional tort remedies to fit the modern requirements of victim compensation in the world of hazardous wastes are obvious. Yet this must be done, in fairness to the consuming public.

I fully support attempts to set up victim compensation funds, as South Carolina had done, from which damage awards can be paid. But a serious disaster can wipe out such a fund, leaving many victims compensated in small part or not at all. In my view, adoption of the strict liability standard should be an integral part of any attempt to solve the victim compensation problem.

The tort system, as modified by such legislation as H.B. 738, is a powerful incentive toward guaranteeing safe handling of hazardous wastes to prevent injuries and deaths from occurring. Victim compensation funds are essential to compensate those victims left out when even the tort system fails, as in the case of bankruptcy or inadequate insurance protections. And federal disaster relief will continue to be necessary when the hazardous waste occurrence is a true disaster.

As a state legislator who has struggled with the complexities of the problem, I applaud the efforts of the members of the committee to find a comprehensive federal approach. Your efforts, if successful, will provide a legacy of safe handling of hazardous wastes for our children and grandchildren.

GENERAL ASSEMBLY OF NORTH CAROLINA

H

SESSION 1983

2

HOUSE BILL 738
Committee Substitute Favorable 7/8/83

Short Title: Strict Liab. Hazardous Wastes. (Public)

Sponsors: Representative

Referred to: Water & Air Resources.

April 7, 1983

A BILL TO BE ENTITLED

AN ACT TO PROVIDE FOR STRICT LIABILITY FOR DAMAGES RESULTING FROM HAZARDOUS WASTES IN NORTH CAROLINA.

The General Assembly of North Carolina enacts:

Section 1. Short title. This act may be referred to as the Hazardous Waste Strict Liability Act of 1983.

Sec. 2. Purpose. The purpose of this act is to provide for a workable strict liability system for hazardous wastes in North Carolina as recommended in the 1983 Report of the Governor's Waste Management Board.

Sec. 3. Creation of a strict liability system for hazardous wastes. Chapter 130 of the General Statutes as it appears in Volume 3B of the General Statutes (and the Cumulative Supplement thereto) is amended:

(1) By adding the following at the end of G.S. 130-166.16:

"(23) 'Claimant' means a person damaged by a hazardous waste occurrence.

"(24) 'Hazardous waste occurrence' means any sudden or non-sudden occurrence in which damages result from any quality or characteristic of a solid waste, as defined in G.S. 130-166.16(16), which quality or characteristic causes the waste to be a hazardous waste under this Article and the rules and regulations adopted pursuant to it.

"(25) 'Strictly liable' means liable without regard to the defendant's negligence or fault. The defendant's foreseeability of danger or risk arising from or injury or other consequences caused by a hazardous quality or characteristic of the waste either at or prior to the occurrence shall not be relevant to a determination of liability.

"(26) 'Caused by' means caused in fact. If the evidence offered by any party tends to show that the damage of which the claimant complains was caused by both a hazardous waste occurrence and other causes, liability under G.S. 130-166.21G shall be limited to damages attributable to the hazardous waste occurrence."

(2) By adding a new section G.S. 130-166.21G to read as follows:

"§ 130-166.21G. Hazardous waste liability.--(a) This section applies only to hazardous waste occurrences caused wholly or partially by a defendant's operations or activities occurring after the effective date of this act. For the purpose of this section, waste polychlorinated biphenyls shall be considered a hazardous waste. Furthermore, for the purposes of this section, governmental immunity from strict liability for bodily injury or property damage caused by a hazardous waste occurrence is hereby waived, but only to the extent that damages do not exceed the amount of damages authorized by the North Carolina Tort Claims Act, G.S. 143-291. Any agency of the State of North Carolina that generates, transports, treats, stores, or disposes of hazardous waste is hereby authorized and empowered to procure proper insurance against such liability..

(b)

(1) Subject only to the defenses set forth in subsections (c) and (e) of this section, the generator, transporter, treater, storer or disposer in control of a hazardous waste at the time of a hazardous waste occurrence shall be strictly liable for bodily injury or property damage caused by the occurrence.

(2) Subject only to the defenses set forth in subsections (c) and (e) of this section, the generator of a hazardous waste, whether or not in control of the hazardous waste at the time of an occurrence, shall be strictly liable for bodily injury or property damage caused by hazardous waste occurrences arising from the hazardous waste generated. Under this subdivision, the generator shall be jointly and severally liable together with the transporter or any other person in control of the hazardous waste at the time of the occurrence. For purposes of this subsection, any person that accepts a hazardous waste from a transporter for storage and causes the hazardous waste to be again

transported shall be considered a generator.

(c) There shall be no liability under subsection (b) for a person otherwise liable who can establish by a preponderance of the evidence:

(1) that the claimant had knowledge of the danger and voluntarily and unreasonably encountered that danger; or

(2) that the hazardous waste occurrence was caused solely by any one of the following:

(i) an act of God;

(ii) an act of war or sabotage; or

(iii) an intentional act or omission of a third party (but this defense shall not be available if the act or omission is that of an employee or agent of the defendant, or if the act or omission occurs in connection with a contractual relationship with the defendant).

(d) Nothing in this section shall bar or otherwise affect the transfer of liability to the Post Closure Liability Fund, under Section 232 of the Federal Comprehensive Environmental Response, Compensation and Liability Act of 1980.

(e)

(1) Subject to the provisions of subsection (i), any defendant who proves that hazardous waste was transferred to and accepted by a hazardous waste facility duly permitted by appropriate regulatory agencies of which he is not the beneficial owner or

operator and that such transfer and acceptance is in compliance with applicable federal and State requirements existing at the time of the transfer and acceptance shall not be liable under subsection (b) for bodily injury or property damage caused by a hazardous waste occurrence after such transfer and acceptance.

(2) When signatures are admitted and established, production of a copy of a hazardous waste manifest entitles a defendant, who according to the manifest generated or transported the waste to a hazardous waste facility, to the defense under this subsection unless the claimant establishes that the waste was not in fact transferred to and accepted by the hazardous waste facility prior to the hazardous waste occurrence.

(3) Each signature on a hazardous waste manifest is presumed to be genuine or authorized unless the party opposing its admission offers prima facie evidence that it is not genuine or authorized.

(f) No punitive or exemplary damages shall be awarded in any action under subsection (b).

(g) Nothing in this section shall deprive a claimant from electing to pursue any other cause of action based upon a hazardous waste occurrence that may exist under statutory or common law, or to deprive a person liable under subsection (b) of any right of contribution or indemnity he may have under law in existence at the time of the occurrence, nor shall anything in this section restrict any right which any person (or class of persons) may have under any statute or common law to seek enforcement of any standard or requirement or to seek the imposition by any State and federal authorities of civil and criminal sanctions. If the principal action was decided on the basis of strict liability, the principles of strict liability shall also apply in any action for contribution or indemnification arising out of the same hazardous waste occurrence.

(h) If any provision of this section or its application to any person or circumstances is held invalid by any court of competent jurisdiction, the invalidity will not affect other provisions or applications that can be given effect without the invalid provision or application; and to this end the provisions of this act are severable."

Sec. 4. G.S. 1-52(16) is amended by changing the second sentence to read as follows:

"Provided that no cause of action shall accrue more than 10 years from the last act or omission of the defendant giving rise to the cause of action; except that for any cause of action arising out of a hazardous waste occurrence as defined in G.S. 130-166.16(24) no cause of action based on strict liability shall accrue more than 30 years from the last act or omission of the defendant giving rise to the cause of action."

Sec. 5. This act shall become effective October 1, 1983.

Mr. Levitas. The final member on the panel we would like to hear from is Ms. Dee Long of the Minnesota House of Representatives.

Ms. Long, we look forward to your presentation.

Ms. Long. Thank you, Mr. Chairman, members of the committee. I want to thank you for the opportunity to be here today to discuss this very substantial issue of great importance to all of us.

I have been asked to address a bill which passed the Minnesota legislature last spring and was signed by the Governor and is now law. The Minnesota bill addresses victim compensation in terms of statutory mechanisms rather than an administrative fund remedy.

Minnesota first considered a State "mini-Superfund," if you will, in 1981. The bill introduced at that time was patterned after S. 1480, the Federal Superfund bill which was not adopted by Congress. This bill contained liability provisions not only for cleanup of hazardous waste sites but personal injury and economic loss damages as well. That bill was heard that particular session in only one committee of the Minnesota House and one committee of the Minnesota Senate.

In 1982, after extensive work over the interim, the bill was heard in 12 committees and subcommittees and passed both the Minnesota House and Senate by wide margins, but was vetoed by then Governor Quie. Again after extensive interim work a revised bill again passed the legislature in 1983 and was signed into law by a new Governor on May 10 of this year.

From the time the bill was first introduced until it was finally enacted, the bill underwent intensive debate, fairly extensive amendment, and was the object of fairly significant controversy of whether we needed the bill.

The citizens in Minnesota have become increasingly aware of the serious threats to public health and the environment posed by the discovery of hazardous wastes not only at sites such as Love Canal in New York, but at sites within our own State. The FMC site immediately north of the city of Minneapolis was rated by the Environmental Protection Agency as the No. 1 site in the Nation.

Following passage of this act, that site has been cleaned up. At the time the bill was being considered by the 1982 legislature, the Minnesota Pollution Control Agency had identified 49 contaminated hazardous wastesites within the State in need of cleanup; that number has now grown to 61, and it is anticipated it will continue to grow. Some of these sites are causing serious pollution to ground water now. Many others will do so in the future if remedial action is not taken.

The Pollution Control Agency estimates it will cost $50 million to cleanup these sites. But that is only part of the problem. Injured victims also face substantial costs. The State Superfund Act addresses these problems, first, by giving the State authority to clean up hazardous waste dumps when there is no one else willing or able to do so. Second, it creates a fund to finance that cleanup. Third, it establishes a clear standard of strict liability for hazardous waste releases in order to make sure that dump sites are cleaned up and victims are compensated for their losses or injuries.

There was actually very little disagreement over the need to cleanup or need for a funding mechanism. The controversy centered specifically on how to deal with the issue of strict liability and over the retroactive application of this liability.

Industry in Minnesota did not seem to oppose applying strict liability for cleanup, but they did object to being held strictly liable for the injuries they cause to people. When the Federal law was passed, it did not address the issue of how to handle compensating victims for personal injury or economic loss. Instead, a blue ribbon panel of noted legal scholars was established to study the issue—this was the 301(e) study group established under CERCLA.

Last fall the panel issued its report; it recommended that States enact laws establishing strict liability for releases of hazardous substances which cause personal injury or economic loss. I am not sure if you heard from Prof. Frank Grad, but one of the bases for the veto in 1982 was the question of constitutionality. That study, and specifically Professor Grad has found there is no constitutional bar for imposing strict liability retroactively.

The Minnesota law does apply retroactively for cleanup and applies retroactively in a limited way for personal injury and economic loss. In its application to personal injury and economic loss, it does not apply for a substance placed in a facility wholly before January 1 of 1960. In addition, there is an additional defense for substances placed between that date and January 1 of 1973. Strict liability will not apply if the defendant can prove that the activity was not an abnormally dangerous one.

The Federal study group also recommended that joint and several liability be applied. The Minnesota law applies full joint and several liability for cleanup but there is only a limited application for personal injury and economic loss; defendants can be held liable for no more than two times their apportioned share. I yiew this as a part of the bill which needs strengthening. I think that, rather than putting a cap on liability for all responsible parties, it would be preferable to establish some level of de minimis exception. For example, a party who could demonstrate that he was responsible for less than 5 percent of the problem could be held liable for no more than his share of the apportioned damages.

The 301(e) study group also noted that proving causation and related evidentiary problems made it extremely difficult for injured victims to be compensated. In addition, the Minnesota authors looked at the findings of the six studies, the study which was prepared for the Congressional Research Service of the Library of Congress during the 1980 Federal Superfund debate, and again were convinced of the extreme problems resulting from causation issues.

The Minnesota Act does have a causation section. Substantial controversy also attached to this part of the bill. The section which was finally adopted as considerably weaker than that which was originally introduced. As it stands now, the law prohibits a directed verdict if the plaintiff can demonstrate a causal link between the defendant, the hazardous release and plaintiff's injury. There is no shift in the burden proof. That remains with the plaintiff, but it is now somewhat easier for the injured victim to get his case before a jury.

The 301(e) study recommended a federally established reviewing agency which was to refer to scientifically established toxic substance documents which show that injury results from such exposure. I am hopeful that Congress will adopt these proposals. It is clear to many of us in Minnesota that the causation issue remains a problem, at both State and Federal levels.

The study group also pointed to the problems which exist in terms of statutes of limitations. The Minnesota courts had already adopted a discovery rule, and we extended this actually in line with a Supreme Court finding for the statute; 6-year statute is common in Minnesota law. The statute of limitations under our Superfund bill stipulates that the cause of action commences, should be determined when the plaintiff discovered the injury or the loss, whether the personal injury or disease sufficiently manifested itself and when the plaintiff discovered or using due diligence should have discovered a causal connection between the injury, disease or loss.

Whether or not we have done enough in Minnesota law to assist injured victims in obtaining adequate compensation remains to be seen. The law has just gone into effect (July 1, 1983). At this time, the only case of which we are aware for personal injury and economic loss is a request to amend a suit which was brought before this bill was passed, and that is currently under consideration.

Assessment of the effects of the law on adequately compensating victims is to be done in a study which will be presented to the legislature next year. That will look at whether we ought to have a State fund and, if so, what form that would take.

I would like to address one additional aspect of the debate over the Minnesota Superfund. The assertion was made by some representatives of the insurance industry and by some hazardous waste generators that if the bill were passed, insurance would be either unavailable or unaffordable. We investigated the insurance issue in depth and heard from a number of insurance representatives. We heard differing views of the situation. Mr. Leslie Cheek, who I believe has testified before this committee, presented one extreme of the testimony we heard. He opposed virtually any change in the law which would ease the plaintiff's burden in recovering for toxic-related injuries and predicted dire consequences should any such change be made.

A different view came to us through a fairly thorough analysis of the bill done by a vice president of the Fred S. James Co. The study was not requested by us but by responsible parties; that being the Minnesota Waste Association, whose membership includes waste haulers and disposers. I have attached a copy of the study to my testimony and the committee should have it available.

Basically this report found that the Minnesota bill did not create any new liabilities for transporters and disposers other than those they would face either under the common law or under Federal law. A number of changes, however, were made in the bill to address the concerns of the insurance industry. We satisfied a number of representatives, but not all of them. In the final analysis, the legislature was convinced that passage of the bill would not make insurance unavailable or unaffordable to Minnesota companies. Since its passage we have seen no evidence indeed that it has.

Although there will still be questions raised regarding insurance and social and economic concerns, I think it is timely, appropriate and just for Congress to enact a Federal cause of action for third party claims arising out of releases of hazardous substances. Specifically, a clear legal standard of strict, joint and several liability needs to be established.

Also, I think the issue of causation needs to be addressed at the Federal level. I would recommend that the committee look at, as I am sure you already have, the model statute proposed by the Environmental Law Institute.

In regard to causation, I think it is imperative for Congress to fund Government research which can come up with scientifically established toxic substance documents that show the causal link between various injuries or diseases and toxic substances. This is an area which should have received greater attention several years ago. It is true that CERCLA has a provision that calls for monitoring hazardous waste dumps for their health effects on adjacent communities. But EPA has given this such low priority that no useful information has been gathered. It is beyond the means of individual citizens and individual States to do the kind of scientific and medical research that needs to be done—provision must be made in the law for the Federal Government to do it and to do it with all deliberate speed.

Although I know that there are many questions yet to be resolved regarding the establishment of a Federal administrative fund, I tend to support its creation in the context of a two-tiered approach as recommended by the study group. The funding for this certainly is up to Congress to decide. However, since the cleanup needs are so great, I believe it is not sufficient to simply extend the present Superfund tax to 1990 and have that money available for victim compensation. I believe that that money is needed for cleaningup the sites.

In conclusion, I support a two-tiered approach to victim compensation: (1) compensation to be paid from a Federal fund administered by the State and comprised of money generated by an industry tax—and possibly general revenue funds, and (2) redress through the State or Federal tort system with a Federal cause of action for third party claims enacted as part of the Federal Superfund statute.

These actions would go far in addressing the question of who should bear the costs of hazardous waste releases. Congress does not have the option of deciding whether there are going to be high costs for hazardous waste releases or whether someone is going to have to pay them. Regardless of what Congress does, or fails to do, the costs will be there and they will be borne by someone. Congress can move to make sure that the burden does not fall on innocent victims by acting affirmatively on these recommendations.

[The statement of Ms. Long follows:]

TESTIMONY OF DEE LONG, MEMBER, MINNESOTA HOUSE OF REPRESENTATIVES

COMPENSATING PERSONS EXPOSED TO THE RELEASE OF HAZARDOUS SUBSTANCES

Minnesota first considered a state "Superfund" in 1981. The bill introduced at that time was patterned after S. 1480, the federal Superfund bill authored by Senator John Culver which was not adopted by Congress. This bill contained liability provisions not only for cleanup of hazardous waste sites, but for personal injury and economic loss damages as well. The bill was heard in only one committee during that legislative session.

In 1982 it was heard in 12 committees and subcommittees, passed both the House and Senate by wide margins, but was vetoed by the Governor. The bill again passed the Legislature in 1983 and was signed into law by the Governor on May 10.

From the time when the bill was first introduced until it was finally enacted, the bill underwent intensive debate and was the object of significant controversy. What motivated the proponents of the bill to stick with the effort to get it passed and what convinced the Legislature that it was what was needed at this time?

Citizens in Minnesota have become increasingly aware of the serious threats to public health and the environment posed by the discovery of hazardous wastes not only at sites such as Love Canal in New York, but at sites within our own state, such as St. Louis Park, Fridley, New Brighton, and Oakdale. At the time the bill was being considered by the 1982 Legislature, the Minnesota Pollution Control Agency had identified 49 contaminated hazardous waste sites within the state in need of cleanup; that number has now grown to 61. New sites are being added at the rate of one a month. Some are causing serious pollution to groundwater now. Many others will do so in the future if remedial action is not taken.

The Pollution Control Agency estimates it will cost $50 million to clean up these sites. But that is only part of the problem. Injured victims also face substantial costs.

How does the State Superfund Act address these problems? First, it gives the State authority to clean up hazardous waste dumps when there is no one else willing or able to do so. Second, it creates a fund to finance that cleanup. Third, it establishes a clear standard of strict liability for hazardous waste releases in order to make sure that dump sites are cleaned up and victims are compensated for their losses or injuries.

There was usually very little disagreement over the need to clean up or for a fund to finance that cleanup. The controversy centered on how to deal with injured victims. Under existing law, it had been virtually impossible for persons harmed by hazardous substances to recover their loss. This act makes recovery only difficult instead of impossible.

Specifically, the controversy centered primarily over the issue of strict liability. Strict liability means that those parties responsible for producing an disposing of hazardous wastes are held legally liable for any damages that result even if actual negligence cannot be proved.

Risks from hazardous substances can never be completely eliminated. A person engaged in an activity involving hazardous substances may take all precautions that are humanly and technologically possible (i.e., he is not negligent) and yet an innocent person may still be injured as a result of exposure to a release. Those supporting the state Superfund believe that question this raises is one of fundamental fairness—should the loss fall on the innocent victim who is injured or on the person who created the risk? The policy of the act is that the loss should fall on persons who create the risk and who are in the best position to control the causes of injury. Thus, those who profit from the use of the substances will bear the cost of any injuries, not the innocent victims of those injuries.

Industry in Minnesota did not seem to oppose applying strict liability for cleanup. But they did not object to being held strictly liable for the injuries they cause to people. When the federal law was passed, it did not address the issue of how to handle compensating victims for personal injury or economic loss. Instead, a blue ribbon panel of noted legal scholars was established to study the issue—this was the 301(e) Study Group established under CERCLA.

Last fall the panel issued its report; it recommended that states enact laws establishing strict liability for releases of hazardous substances which cause personal injury or economic loss. Our state Superfund does that. The panel did not recommend for or against retroactive application; it left that decision to the states. However, the head of the study found that there is no constitutional bar to imposing strict liability retroactively, but rather that it is essential "because otherwise the victims would be without any effective remedy."

The Minnesota law does apply retroactively for cleanup and it has limited retroactive application for personal injury and economic loss.

The 301(e) Study Group also recommended that "joint and several liability was a useful and necessary rule to allow recovery by a plaintiff who had a valid claim, but who could not pinpoint the precise contribution to his injury by each of several defendants. Joint and several liability and the adoption of an expanded approach to concert of action would allow the allocation of liabilities among a group of defendants by the defendants themselves."

The Minnesota law applies full joint and several liability for cleanup but there is only a limited application for personal injury and economic loss; defendants can be held liable for no more than two times their apportioned share. I view this as a part of the bill which needs strengthening. I think that, rather than putting a cap on liability for all responsible parties, it would be preferable to establish some level of de minimis exception. For example, a party who could demonstrate that he was responsible for less than 5% of the problem could be held liable for no more than his share of the apportioned damages.

The 301(e) Study Group also noted that proving causation and related evidentiary problems made it extremely difficult for injured victims to be compensated. The Group found that "regardless of the cause of action—whether trespass, nuisance, negligence, riparian rights, strict liability or any other—the establishment of the causal connection between the exposure to hazardous wastes and the injury or disease suffered remains a difficult evidentiary problem because of long latency periods and the variety of exposures from one or more disposal sites or other potential causes of injury or disease."

The Study Group recommended that "the several states enhance and develop common law and statutory remedies, and that they remove unreasonable procedural and other barriers to recovery in court action for personal injuries resulting from exposure to hazardous waste, including rules relating to the time of accrual of actions, joinder of parties, apportionment and proof of causation."

In addition to the findings of the 301(e) Study Group, the authors of the Minnesota Superfund also found evidence for the need to address the issue of causation in the Congressional case study of six states on 3,600 incidents of toxic substances-related pollution. (Six case studies of compensation for toxic substances pollution: Study prepared by the Environmental Law Institute for the Congressional Research Service of the Library of Congress, at the behest of the Senate Committee on Environment and Public Works during the 1980 federal Superfund debate over victim compensation.) The summary of the Six Case Studies notes that:

"At least three things are immediately apparent from this study of harm and compensation in six states. First, the legal mechanisms in the states studies are generally inadequate for redressing toxic substances-related harms. Traditional tort law presents substantial legal barriers to recovery. For example, for chronic long-latency diseases associated with exposure to toxic substances it is difficult to develop legal proof that a specific substances was the proximate cause of particular injuries.

"Second, seeking compensation for pollution-related injuries is usually cumbersome, time-consuming, and expensive. Private parties may be unable to establish the complex technical findings for obtaining redress. Thus, injured parties in these six states filed few cases and rarely obtained final judgments. Of over 50 damage suits noted, only one was even partly resolved by judgment; the others were settled.

"Finally, and perhaps most important, the result of these difficulties is that the compensation ultimately provided to the injured parties in these cases is generally inadequate. Although the number of cases studied is small, this study suggests that the available avenues of legal redress and the compensation provided for environmenal pollution in other states may also be inadequate."

The Minnesota act does have a causation section. Substantial controversy also attached to this part of the bill. The section which was finally adopted was considerably weaker than that which was originally introduced. As it stands now, the law prohibits a directed verdict if the plaintiff can demonstrate a causal link between the defendant, the hazardous release and the plaintiff's injury. There is no shift in the burden of proof—that remains with the plaintiff, but it is now somewhat easier for the injured victim to get his case before a jury.

I think the causation section of the Minnesota law does not go far enough in easing the burden of proof on claimants. The 301(e) study proposed that they would merely have to prove an injury and exposure to a toxic substance, not a cause and effect relationship. A federally-established reviewing agency was to refer to scientifically established toxic substance documents which show that injury results from such exposure. I am hopeful that Congress will adopt these proposals. It is clear to many of us in Minnesota that the causation issue remains a problem, at both state and federal levels.

"Proving causation is clearly the most difficult factor in a hazardous waste suit and presents a burden so great that common law actions in this area are *proven losers.*" (W. Rogers, *Environmental Law,* Sec. 61.0 at 694 (1977); see Pfennigstorf, Environment, *Damages and Compensation, Am. B. Foundation Research J.*, 347, 353 (private common law actions not viable alternative to administrative controls). See also Trauberman, "Compensating Victims of Toxic Substances Pollution" An Analysis of Existing Federal Statutes, 5 *Harvard Law Review* 1,3 (1981).)

"For many parties the common law will prove inadequate to deal with the unique problems presented in a hazardous waste case. Because of the scientific uncertainty which surrounds this entire area a plaintiff will likely find it impossible to obtain evidence that will satisfy the traditional standards of proof." (Christine Ver Ploeg, *Suing on Behalf of the Victim of Hazardous Wastes: Minnesota Common Law and Statutory Relief*, (1982), (from a report for William Mitchell College of Law), p. 88.)

The 301(e) Study Group also pointed to problems which existing statutes of limitations could present to injured victims. There was little or no controversy on this issue when the bill was being debated. As adopted I believe the Minnesota law fully addresses the issues raised by the 301(e) Study Group and thus I believe the Minnesota statute could serve as a model for a federal law. It provides:

"No person may recover pursuant to sections 1 to 15 unless the action is commenced within six years from the date when the cause of action accrues. In determining when the cause of action accrues for an action to recover damages for death, personal injury or disease, the court shall consider factors including the following:

"(a) When the plaintiff discovered the injury or loss;

"(b) Whether a personal injury or disease had sufficiently manifested itself; and

"(c) When the plaintiff discovered, or using due diligence should have discovered, a causal connection between the injury, disease, or loss and the release of a hazardous substance."

Whether or not we have done enough in the Minnesota law to assist injured victims in obtaining adequate compensation remains to be seen. The law has just gone into effect (July 1, 1983). At this time, the only case of which we are aware is a request to amend a suit which was brought before this bill was passed. The request is to add a count under the provisions of the Environmental Response and Liability Act (Minnesota Superfund).

An assessment of the effects of the law on adequately compensating victims is to be done in a study which will be presented to the Legislature next year. That same study will also make recommendations on the creation of a victims' compensation fund, including the appropriate scope of compensation, methods of financing compensation, and whether the fund should be established or administered at the federal or state level and the appropriate degree of state and federal cooperation in providing compensation. This study was mandated in Section 30 of the state Superfund law, Chapter 121, *Laws of 1983*.

I would like to address one additional aspect of the debate over the Minnesota Superfund. The assertion was made by some representatives of the insurance industry and by some hazardous waste generators that if the bill were passed, insurance would be either unavailable or unaffordable. We investigated the insurance issue in depth and heard from a number of insurance representatives. We heard differing views of the situation. Mr. Leslie Cheek, who is Vice President for Federal Affairs of the Crum and Forster Insurance Companies and speaking for the American Insurance Association, presented one extreme of the testimony we heard—he opposed virtually any change in the law which would ease the plaintiff's burden in recovering for toxic-related injuries and predicted dire consequences should any such change be made. A different view was presented in a thorough analysis of the bill which was done in a study entitled "Availability of Pollution Liability Insurance Under Proposed State Superfund Legislation." The paper was prepared by Rodney J. Taylor, Vice President, National Services Division, Fred S. James and Company, Chicago, Illinois. The study was not requested by legislative staff, but by potential responsible parties—the Minnesota Waste Association, whose membership includes waste haulers and disposers. Because the study seemed to be balanced and comprehensive, I have attached a copy of it. Basically, Mr. Taylor found that the Minnesota bill did not create any new liabilities for generators, transporters and disposers than what they would likely face under common law. In addition, it seems to me he put the role of insurance in perspective when he stated:

"It is important to recognize that insurance cannot solve all of the problems associated with the disposal of hazardous substances. The current crisis in waste disposal in this country is a complex problem brought about by many factors including decades of improper disposal practices. These problems will only be resolved by decades of attention to correcting past errors and a significant financial commitment to restoring what has already been damaged. Insurance for pollution liability may be a part of the solution to these problems, but it obviously is only a small part."

A number of changes were made in the bill to address the concerns of the insurance industry. We satisfied a number of representatives, but not all of them. In the final analysis, the Legislature was convinced that passage of the bill would not make insurance unavailable or unaffordable to Minnesota companies. This belief seemed to be borne out in a presentation made by William A. Mahoney, Vice President, Marsh and McLennan, Incorporated, New York, at a hazardous waste seminar held in Minnesota on May 23, 1983 (two weeks *after* the bill had passed). Mr. McLennan noted that:

"Capacity, which was a problem originally, is no longer. There are many more companies willing to write the coverage and capacity is steadily increasing. Originally an individual company would consider five million and ten million annual aggregate as its capacity for any one risk. But we are seeing an increase to ten million and twenty million annual aggregate with additional reinsurance capacity coming about in a rather expeditious fashion. Considering that two years ago there were only three underwriters interested in writing the gradual pollution while today there are at least a dozen, it is obvious that there has been substantial growth.

"Hopefully, as more underwriters become interested we will see more competitive pricing, although pricing has not been without fair competition. Premium costs have been set upon the basis of the corporation's sales and credits are granted for self-insurance and deductibles, as well as the underwriter's consideration as to how well the firm is managing its hazardous waste.

"Dealing with hazardous waste is to be involved with the concept of loss prevention and if a firm is able to demonstrate that it is loss prevention conscious, it probably will warrant a premium consideration when the terms of the contract are being negotiated with the underwriter.

"This entire subject of environmental impairment liability insurance is one which is constantly changing. There is no doubt that this mode of constant change will continue for the next several years.

". . . . The policy forms are changing, the excess markets are seriously considering getting involved, and there is every indication that the entire insurance industry—from the primary placement up through the excess layers—will be ready and willing to accept pollution liability insurance risks. Much the same as they accept any other form of insurable risk."

Although there will still be questions raised regarding insurance and social and economic concerns, I think it is timely, appropriate and just for Congress to enact a federal cause of action for third party claims arising out of releases of hazardous substances. Specifically, a clear legal standard of strict, joint and several liability needs to be established.

Without a definite and specific legal standard for hazardous waste cases, each case will require lengthy and expensive court action. Such legal action is beyond the means of the average person. The Comprehensive Environmental Response, Compensation and Liability Act (CERCLA) should be amended to set out legal responsibilities for personal injury and economic loss clearly and with certainty for all parties involved, thus making it more likely that innocent victims will be justly compensated.

As I noted above, the issue of causation needs to be addressed. I recommend that the model statute proposed by the Environmental Law Institute in its study on compensating victims be used as the basis for federal legislation. (See Jeffrey Trauberman, Statutory Reform of Toxic Torts: Relieving Legal, Scientific and Economic Burdens on the Chemical Victim, Environmental Law Institute, Washington, D.C., 1983).

In regard to causation, I think it is imperative for Congress to fund government research which can come up with scientifically established toxic substance documents that show the causal link between various injuries or diseases and toxic substances. This is an area which should have received greater attention several years ago. It is true that CERCLA has a provision that calls for monitoring hazardous waste dumps for their health effects on adjacent communities. But EPA has given this such low priority that no useful information has been gathered. It is beyond the means of individual citizens and individual states to do the kind of scientific and medical research that needs to be done—provision must be made in the law for the federal government to do it and to do it with all deliberate speed.

Although I know that there are many questions yet to be resolved regarding the establishment of a federal administrative fund, I tend to support its creation in the context of a two-tiered approach as recommended by the 301(e) Study Group. The level of compensation suggested by the 301(e) Study Group also would seem to be fair and appropriate; full recovery of medical costs plus two-thirds of lost job income up to a monthly limit of $2,000 which could be adjusted to reflect cost-of-living changes.

The monies for the fund should be generated by a tax on industry—Congress may want to consider whether this tax should be on chemical feedstocks, like the current Superfund tax, or whether it should be a waste end tax along lines established in the Minnesota Superfund and like that set forth in Senator Gary Hart's bill, S. 860. It is possible that a combination of the two would be the best approach. Since cleanup needs are still so great, I believe it is not sufficient to simply extend the present Superfund tax to 1990 and have the money that would be raised used for compensating victims. The present tax does need to be extended—but it needs to be used for cleaning up hazardous waste sites. The tax for compensating victims must be in addition to the cleanup tax. Rather than set this new tax at an unduly burdensome level, it may be reasonable to appropriate some general revenue funds to augment the tax receipts. Senator Hart's bill, S. 860, would authorize $190 million per year in federal funds to be added to the Superfund tax program for each of the next 10 years.

In conclusion, I support a two-tiered approach to victim compensation: (1) Compensation to be paid from a federal fund administered by the state and comprised of monies generated by an industry tax (and possibly general revenue funds) and (2) Redress through the state or federal tort system with a federal cause of action for third party claims enacted as part of the federal Superfund statute.

These actions would go far in addressing the question of who should bear the costs of hazardous waste releases. Congress does not have the option of deciding whether there are going to be high costs for hazardous waste releases or whether someone is going to have to pay them. Regardless of what Congress does, or fails to do, the costs will be there and they will be borne by someone. Congress can move to make sure that the burden does not fall on innocent victims by acting affirmatively on the recommendations I have outlined above.

Re: Subcommittee on Investigations & Oversight
Hearings of November 8 & 9, 1983

Dear Mr. Italiano:

I previously forwarded to you the American Insurance Association's comments in response to the testimony heard by the Subcommittee on November 8 and 9.

With his permission, I am forwarding to you a copy of a letter dated November 23 received from William Mahoney of Marsh & McLennan with reference to the testimony of Representative Dee Long on November 8. If possible, I would hope that you would make this letter part of the record of your Subcommittee hearings on Hazardous Substance Victim's Compensation as I believe this letter accurately places the context for Mr. Mahoney's remarks referred to by Ms. Long.

Very truly yours,

M. Patricia Casey

Re: Victim Compensation Proposals

Dear Ms. Casey:

I appreciate the concern you expressed to me in our telephone conversation of November 21st regarding certain testimony apparently given to a governmental committee in which I was quoted extensively.

On May 23rd of this year I was invited by the Minnesota Waste Management Board to address the subject of Environmental Pollution Liability Insurance which I did.

Attached is a capsulized version of my my discussion. My comments addressed the EIL markets, the various insurance forms and some of the industry's concerns with respect to the general subject of pollution coverage.

Past history of the coverage, while admittedly brief, was touched upon and I did distribute written material which contained information supporting the development and the changing scene in respect to this "new" insurance coverage beginning approximately in 1980.

I was not asked, nor did I attempt to analyze the Minnesota Statute, which had been enacted only a few weeks prior to this public conference. I positively made no attempt to characterize my remarks as indicative of the insurability that would support "Victim Compensation Legislation". The subject of Victim Compensation is in such an embryonic stage that I could not attempt to relate insurance to a subject which has within it the very important question of "no fault" responsibility.

Marsh &
McLennan

My comments should not ever be construed to have application to such a complex subject which is recognized as such by Sections 29, 30 and 31 which requires studies to be made with respect to sections concerning liability and includes a study of the insurance industry, as well as other affected industries. The first of these reports are not due until July 1, 1984 and some are due in 1985.

I have spoken with Sue Robertson of the Minnesota Legislative Commission on Waste Management, since she participated in the panel discussion. She assured me that the comments attributed to me by the witness were not in answer to any legislative consideration of "Victim Compensation". She has offered to send me the testimony, as you have.

I regret the confusion that appears to be surrounding the question and it is also unfortunate that I was not contacted before the comments were made in a committee environment that could possibly be misinterpreted.

I have consistently underscored in any comment I have made, that this particular market is constantly changing and this observation is never more clearly demonstrated than what is occurring in some of the insurance forms at this very moment and which will result in a restriction of coverage which was available last May.

I would be more than pleased to assist in clearing up any confusion which has been created by someone else using my words, but not necessarily using them in the proper reference.

Sincerely,

William A. Mahoney

Long-Term Responsibilities

Legal Liability at Minnesota's Hazardous Waste Disposal Site

Who should bear the legal liability for a potential release of hazaruous wastes from the disposal facility to be sited by the Waste Management Board: hazardous waste generators, the disposal facility operator, the state, or a combination of any of these parties?

This was the question moderator Marcia Gelpe, a professor at William Mitchell College of Law, posed to the panel session entitled "What Long-Term Safeguards Are Needed?"

In May 1983, the Legislature approved a new state Superfund bill designed to provide for speedy clean-up of Minnesota's hazardous waste dump sites and statutorily define the legal liability for property damage and personal injuries caused by past and future releases of hazardous wastes.

Prior to passage of the bill, business and industry groups lobbied heavily against the "strict, joint, and several" legal liability provisions it contained. "Strict" liability enables a victim of a hazardous waste release to sue for damages without having to show negligence on the part of the generator of the wastes. And, generally, "joint and several" liability provides that, if a number of generators deposited wastes at the problem site, each is potentially liable and could be required to share in the damages.

The bill also requires generators to be "strictly" liable for all hazardous wastes disposed since 1973 and makes it easier for victims injured by wastes disposed between 1960 and 1973 to recover damages if they can prove the generator's hazardous waste activities were "abnormally dangerous."

After Governor Rudy Perpich signed the Superfund bill into law, Lewis Lehr, chief executive officer of 3M, Inc., stated in a letter to Perpich that: "3M believes the liability provisions of the present bill will make it impracticable for waste generators to use any designated hazardous waste site in Minnesota."

Panelist G. Robert Johnson, a Minneapolis lawyer and lobbyist for 3M, agreed with Lehr's assertion.

"I don't know how any business could justify the decision to use a site that it didn't locate, didn't design, and doesn't operate and yet. . .bear liability for what happens at that site through no fault of its own," Johnson said.

Rather than requiring businesses that use the disposal facility to share liability for any damages, Johnson believes the State of Minnesota should bear the ultimate liability for the facility it will site and own. "It would seem to me, that for generators to utilize the Waste Management Board process of treating wastes to the fullest extent, you have to hold out some sort of carrot — such as termination of liability. After all, it's going to be very expensive for generators to fully process their wastes," he said.

Solving a complex issue

State Representative Dee Long, who authored the House version of the Superfund bill, disagreed. "I think that is a very simplistic solution to a terribly complex issue," she said.

According to Long, legislators were not willing to put such language into the Superfund law in 1983 because such issues as control and regulation of the facility, availability of insurance, and the financial capability of businesses who use the facility have not been addressed. Instead, she said, the Legislature included a provision in the bill requiring the Waste Management Board to make recommendations to the Legislature by November 1 regarding the allocation of liability among owners, operators, and users of Minnesota's hazardous waste disposal facility.

To Address [illegible]

Long said a "great deal" of damage could have been done by incorporating into the bill a provision terminating the liability of hazardous waste generators once their wastes reach the state-sited facility. Such a provision would have created "innumerable" problems for the Waste Management Board's siting process and residents in the areas the Board is considering as potential disposal sites, she said.

"We're calling for a very thorough study of a complex problem. And what I don't understand is how the industries in this state that have said they will never use a site in Minnesota have chosen to totally disregard the provision for a study of this issue," Long added.

Chuck Riley, a member of the audience from the Michigan Department of Natural Resources, warned Minnesotans to be cautious in determining liability for the disposal facility.

Riley explained that in 1979 the State of Michigan attempted to absolve hazardous waste transporters and generators of liability for their wastes once they were disposed at a state-approved facility. However, Riley said, the EPA objected to this provision and the Michigan attorney general determined that it was not legally possible to absolve generators and transporters of legal liability for their wastes.

A similar effort to absolve disposal facility operators of their liability, in which the State of Michigan would assume ownership of the facility after it was closed, was ruled unconstitutional by the State attorney general, Riley said.

"There are a lot of implications to transfer of liability and I think you ought to think long and hard on it before you put it down in writing and have someone overturn it in court," Riley concluded.

Rep. Dee Long (DFL-Minneapolis)

"You have to hold out to industry some sort of carrot"

Prof. Marcia Gelpe

Robert Johnson

"That's a simplistic solution to a complex issue"

William Mahoney

The view of an underwriter

Panelist William Mahoney, vice president of the New York insurance brokerage firm of Marsh and McLennan, explained that an insurance company might look more favorably on a disposal facility operator that shares legal liability with a state or municipal government. "Anytime a disposal facility operator can show some minuses coming off the total loss picture, the facility operator will get some benefit in containing premium costs," Mahoney said.

Mahoney also said that it would be possible for a generator who deposits waste at a facility to "piggyback" on the operator's insurance, although many operators would be hesitant to do this because it would reduce their limits of coverage.

Mahoney noted that, while the federal Superfund law does not contain a provision for "strict, joint, and several liability" of hazardous waste generators whose wastes cause personal injuries, federal officials have indicated they will enforce the law as though it contained such a provision. Initially, this caused some concern among insurance brokers around the nation.

"For the most part, those concerns have been put aside by the insurance industry. We have found that most underwriters want to insure for legal liability, and if it is strict liability, then that is what they will insure for."

NOT
NO-FAULT
BUT.
STRICT
DUTY
TO
OBSERV

Another panelist, Sue Robertson of the Minnesota Legislative Commission on Waste Management, pointed out that because federal officials intend to enforce a strict, joint, and several legal liability standard, Minnesota generators who try to avoid such liability in Minnesota by shipping their wastes to facilities in other states could end up with the same liability anyway.

In essence, Robertson said, Minnesota's liability standard is very similar to the federal standard.

Mahoney also discussed factors underwriters evaluate in determining whether to insure a firm that handles hazardous wastes. "One of the most essential points about this type of insurance is loss prevention," he said. "If a firm deals with hazardous wastes and is sloppy, it is not going to get insurance quite as readily as a 'clean' firm giving its all to loss prevention."

Mahoney stressed that insurance is not the answer to the hazardous waste problem, but that it could assist in restoring lost public confidence in hazardous waste management techniques. "Insurance can be written, but it is not going to be written for every single facility," he said. "However, if a facility is properly located, carefully engineered, and the operators are conscious of loss prevention, it stands a better chance of getting insurance."

Mr. LEVITAS. Thank you very much, Ms. Long. Your closing comments are so very apropos and right on target. The costs of hazardous waste in this country is a fact. How that cost is borne and how enormous it gets to be is still something we can deal with. But the $40 to $50 billion we are now looking at just for cleanup doesn't begin to address the extended impact both on our natural resources, the aquifers, the other water resources, and, as all three of you are addressing today, the individuals who have been exposed to this.

Let me start with you, if I may, Ms. Long. You note on page 7 that the statute enacted by the Minnesota Legislature "fully addresses the issues raised by the 301(e) Study Group." And you also note on the same page that the Minnesota law is still too new to evaluate in terms of its effectiveness or adequacy.

My question is this: In light of your comments, do you feel that at this time there is further need for the Federal Government to take any action either in terms of providing the Federal cause of action or the two-tier approach which you seem to support, or should we for the time being leave it to the respective States to carry out until we have had some more experience under these efforts that are going on around the country?

Ms. LONG. Mr. Chairman, it is my belief that waiting will not accomplish any substantial purpose. It may be years before the effect of State actions is apparent. While States are gradually taking this approach, you have at that point an inequity among States. I support a Federal cause of action enacted as soon as possible. And I support the two-tiered approach.

Mr. LEVITAS. Mr. Connally, would you comment on that?

Mr. CONNALLY. I would agree with Ms. Long. There are really only a handful of States that are legislating in this area seriously at the present time. There are some unique factors which have happened in those States that have brought it to the attention of the local legislators. Your opening comments were right on point in indicating that there are little time bombs all over the country that haven't gone off yet. So it is a function of when those start popping before those States act.

You ought to move now. I think you ought to recognize in moving now that the area is complex enough that there will be initial errors, as indeed California has, and then come back and do the second- and third-year cleanups as we all do on major pieces of legislation. But I would urge you to go forward.

Mr. LEVITAS. Mr. Hackney?

Mr. HACKNEY. I concur, Mr. Chairman. I might say in addition that this may be an area where the States are following the Congress instead of the other way around, as you indicated sometimes happens, because our own particular orphan site legislation is modeled on the Federal cause of action in this area. We hope that bill will pass also in the 1984 short session.

I think, if I may repeat something I mentioned earlier, perhaps some Federal incentive toward State tort law reform might be in order if a Federal cause of action for personal injuries is not created.

Mr. LEVITAS. Before we get away from this point, one of the problems that I have in thinking in terms of a Federal cause of action is the fact that it means another 1,000 or 10,000 suits in the Federal court system, rather than in the State court system. And, it is certainly an easy response when we in Congress look at problems to say let us pass a law. Let us create this cause of action, whether it is on debt collection or on certain other traditional State tort areas.

Do you see the opportunity of perhaps creating a Federal cause of action but one which could be litigated in the State courts rather than in the Federal courts? Any of you?

Ms. **Long**. Mr. Chairman, I would look favorably on that approach.

Mr. **Levitas**. Mr. Hackney?

Mr. **Hackney**. Mr. Chairman, I noted, in light of your comments, with some interest in the Post this morning there are hearings going on elsewhere up here today on the overload of civil cases in the Federal court system, which is, as you all know, a very serious problem. I think it is imperative that there be access to the State courts in these situations. I think that is where torts are traditionally tried except for unusual situations, and I think that is where these ought to be tried as well.

Mr. **Levitas**. Thank you. Let me ask a more difficult and troubling question. I ask it not just to be the devil's advocate but because we have had rather strong testimony before this subcommittee along these lines.

There are those who claim that there is no scientific evidence that links hazardous waste sites, or for that matter even toxic chemical waste, with physical injury, and that what we are doing, these people charge, is finding a solution for a problem that doesn't exist except by way of perception. We have had scientific witnesses come before this subcommittee and say there is no evidence that living near or on top of a hazardous waste site in fact leads to physical injury and that we are simply making a political response to a scientifically unjustified assumption.

My question is did you have that type of argument presented to your respective State legislatures as you were going through this process? And would you care to comment on the assertion in general; are we in fact fashioning a remedy for a problem that doesn't exist? Why don't we start at this end this time, Mr. Hackney?

Mr. **Hackney**. Mr. Chairman, that argument I suppose has some appeal. I don't think we can ever get away from the problems of proof. You are going to have to prove causation in some way or another or you can't recover unless someone reverses the burden of proof. I don't think that is seriously about to happen.

Now, I would point out, however, that there are many, many other smaller injuries which are perfectly susceptible of proof wherein a manufacturer, transporter, or generator ought to be strictly liable. Those include, for example, tanks of chemicals going down the highway. There ought to be incentives so that whether or not the driver of the truck is negligent and if there is spillage there is a strict liability standard. Generators and transporters are responsible for getting the wastes safely to their ultimate destination, and they are responsible for having the wastes in safe enough containers that, if there is an accident, it won't hurt somebody or get in the water supply. Those kinds of things are perfectly susceptible of proof.

To the extent the argument against such legislation depends on the inability of someone to prove current injuries for something that happened 30 years ago, yes, that is a problem. We can't get away from that. But that doesn't mean we don't need to start and go ahead.

Mr. LEVITAS. Mr. Connally, would you comment on that?

Mr. CONNALLY. Yes. We have had substantial testimony from some of the same folks who spoke to your committee, who did not take that line in terms of the presentation to the California Legislature. There was not the dispute that there is a problem, so much as yes there is and how do we go about it. There was substantial evidence presented that there are extreme difficulties in making that causal connection in terms of the costs of the scientific studies. But there was not the assertion by the credible opponents of the two-tiered system that you have heard here that in fact there was not a problem, and therefore you should not be legislating in this area.

Some of the representatives from the chemical industry would acknowledge merit to rebuttable presumptions of some type if you have proof: One, that there is a toxic there, two, that the person was exposed, and three, that there are medical symptons caused by those toxics, if you capped it with some recovery. They acknowledged that type of presumption was not out of line.

Now, this was not all of them, but there were a few that made this point. So on the contrary, it is an appropriate area to look at, an appropriate area to legislate. It is a real problem. The only thing is all we see now is the head and neck of the camel, and it is going to be another 10 or 15 years before we see the rest of it.

Ms. LONG. Mr. Chairman, I would echo those remarks. We certainly heard many objections throughout the struggle with the Minnesota bill that indeed we were addressing a non-existent problem and what was the need for that. Our rejoinder always was, then what are they worried about since even under our fairly liberal legislation it seemed highly unlikely that unjustified victims would be compensated.

I again echo the comments of Mr. Connally, that I think there are a number of potential cases out there. There may be some actual cases not yet ripe. In the State of Minnesota there are not yet a great number of cases. But the Minnesota Pollution Control Agency really just started keeping a log of these hazardous sites about 3 years ago. And they are finding new ones all the time. I think there is a time lag there. The opponents of the legislation who make that argument do not acknowledge the time lag problem.

Mr. LEVITAS. Thank you. I think that I get from all three of you the feeling that there is sufficient evidence that says if we have to err in this matter, we should err on the side of protecting the public and then take a closer look at it as this epidemiological and other evidence is produced over the years.

Tomorrow our witnesses will include some people from the National Institute for Occupational Safety and Health and from the centers for Disease Control. We will get into some of these questions, but I think the experience you have had is extremely helpful to us.

One last question, and then I will recognize the gentleman from Florida. This is to you, Mr. Connally. A number of witnesses—you touched on it in your last answer—who have testified before this committee have argued that the problem of causation is the plaintiff's, or the victim's most difficult obstacle. It is the highest hurdle that they have to overcome, proving the injury results from exposure to hazardous substances.

Some of these witnesses have suggested adopting concepts like a rebuttable presumption where the burden of proof that there was no harm would shift to the generator rather than requiring the victim to show by a preponderance of evidence that the injury was caused by the particular exposure, and that this type of approach would remove the unreasonable barrier that we have heard testimony about.

Now it is my understanding that the California statute does not change the traditional legal approach to establishing causation. Was this because the California Assembly rejected the argument that the burden of causation is too difficult for the plaintiff to prove, or was there some other reason that led to the decision not to shift that burden of proof?

Mr. CONNALLY. This is an issue over which reasonable people can differ. And there is a very powerful and effective lobby in California from the chemical industry, the petroleum industry, the Manufacturers Association in particular, against changes in this area.

The bill, as introduced, did in fact include some rebuttable presumptions very similar to that proposed by the 301(e) study group. Those presumptions were gutted in the text of the hearings on the bill. Under that, if you do that, you negate the very reason for the first tier remedy at all. If you say we are setting forth a first tier administrative claim remedy because it is too expensive to go to the courts and prove that causal connection, and then you take that same causal requirement and put it in the first tier, the only thing you have done is you have shifted the deep pocket from Du Pont Corp. to the fund, and the proof burden is exactly the same. The cost of meeting that burden is exactly the same.

You have done what, unfortunately, California has done, and that is provide no real remedy at all. You have identified one ineffective remedy and set forward a second equally ineffective remedy. So you have to get at this area of presumptions. If you cannot, if you cannot buy off or convince your colleagues to go with the rebuttable presumption and the entirety of it, at least go the rebuttable presumption and then put some type of cap as to the amount of money you can recover for damages you incur in reliance upon that presumption.

For example, if your claim is vested upon a rebuttable presumption only, you can recover 50 percent of the direct damages you experienced. If you move the continuum away from the rebuttable presumption back to the causal connection, you will deny the remedy; you should not legislate in the area; the first tier is a waste of time; it is a bad, bad trick on the public and the citizens of California are just waking up. If you have that rebuttable presumption in there and if you must grade it based on some damage recovery formula, at least there is something there for the victims that is real.

Mr. **Levitas**. Do either of the others of you have any further comments on that point?

If not, let me say this, Mr. Connally: I totally agree with you. At the very least, the tradeoff for a limitation of liability should be this rebuttable presumption, if not absolute liability of some sort. If we are going to set up a first tier mechanism with some administrative remedy, and a workers' compensation type of approach, then quite obviously there has to be a totally different approach to the proof question for that type of system. Otherwise, as you say, you are playing a trick on the public. And, hopefully the public will wake up in California and realize that in this instance the chemical industry got the best of both worlds and did not even suffer the obligation of addressing the question of compensation even in that first tier.

The gentleman from Florida, Mr. Shaw.

Mr. **Shaw**. Thank you, Mr. Chairman.

I would like to pursue that line of questioning of the chairman. I want to talk a little bit about the rebuttable presumption, which we know—and I think it is absolutely clear—that strict liability and preponderance of evidence or rebuttable presumption are certainly compatible under the law.

I seem to have, however, detected a difference of opinion between Mr. Hackney of North Carolina and Mr. Connally from California as to what the burden of proof should be.

Mr. Connally, how would you draft a rebuttable presumption? Would it be a rebuttable presumption such that someone just comes in with injuries which are classic to exposure to a certain substance, and then shows that he was at some time around that substance; then it would become the responsibility of the Government, the State of California, if you may, to rebut the presumption that that is how he got his injuries? How would you draft such a bill?

Mr. **Connally**. Mr. Shaw, initially Mr. Hackney and I were speaking to burdens of proof in two different systems. Mr. Hackney was speaking to the tier 2, as I understand it, general liability tort recovery mechanism, talking about the strict liability process applying there. My discussion was about the rebuttable presumption to tier 1. I think the rebuttable presumption identified in your study group was a consensus recommendation, and that is pretty startling given the broad makeup of that study group where you prove, one, the existence of the substance, two, exposure, and then three, the individual suffered the kind of medical harms that exposure to that particular substance would bring about in laboratory experiments and so forth. That is the type of presumption that I think you ought to move for.

Ms. Long points out in her testimony—and I think there is credence to that, and the study group mentions it also—that in formulating these presumptions based on exposure there has to be some work done, epidemiological work done of a broad character so that that causal connection in general is proved. But once it is proved that exposure to dioxin produces *x* result, and if Mrs. Jones has been exposed to dioxin and then she has *x* result, then it ought to be the burden of the industry at that point to prove that in fact there is some other substance or something else that is causing *x* result.

In the absence of that occurring, there is no real recovery for Mrs. Jones if she is a small claimant because she cannot incur the individual cost to make that connection herself.

Mr. Shaw. I understand that, and I can appreciate that.

I think that in earlier comments by you and by the Chairman, and certainly through my own knowledge, there are people who come in and simply deny the causal relationship. I think that we can also find that people will say that cigarettes are not injurious to your health.

I am a little curious as to how or where would you find the burden of proof shifting? Someone comes in with exposure to something that could be a cause of lung cancer. So at that point it is shown that that particular individual also smokes. Now, has the burden shifted at that point? Where do you stand?

I don't know how you would draw the legislation to come up with those presumptions. That is what is concerning me.

Mr. Connally. What we do in California in the workers' comp field—it has similar kinds of presumptions in a variety of areas—is that if in fact there are multiple causative factors, then the defendant or respondent has to come in and prove and rebut the presumption that indeed this individual has smoked throughout the entirety of their life; they smoke two packages of cigarettes a day. Based on the fact they have had one or two exposures to this toxic substance, which is carcinogenic, on your lungs, it is not reasonable in this instance to assume and to give them the benefit of the presumption that their lung cancer is caused as a result of that one- or two-incident exposure.

But that presumption can be overcome, and it can be overcome based on the submission of the kind of evidence that you have outlined. But the trier of the fact can look at that evidence and make that determination. But the individual initially has the benefit of that assumption. And it makes all the difference in the world as to whether or not the people, particularly those people that have valid claims, are going to recover.

Now, there is one question that you didn't ask that I would think would be a followup, and that is, are errors going to occur? And the answer to that question is yes. Are some people going to receive benefits that probably should not? And the answer to that question is yes. But if the system is structured properly, it is going to be very, very small. And that is an error risk I think we ought to be willing to accept, given the fact that these people were the people who need and are justified in recovery, of no other basis for recovery, in the absence of that mechanism in existence.

Mr. Shaw. I think, as the chairman said, if you are going to err, err on the side of the victim.

In Federal legislation, where would be your election of remedies where you could pursue a claim in either direction?

Mr. Hackney, would you like to comment on that, or any of the other panelists?

Mr. Hackney. I am not sure of your question, sir.

Mr. Shaw. The question is, if you have a remedy under both Federal law and State law, would it be your understanding that the individual would have to elect which law under which he is going to pursue his claim, and then be bound by that decision and not be able to go back and do some shifting at a later date?

Mr. Hackney. I believe, Congressman, the legislation that I have seen at the State level all refers to the Federal legislation and requires that there be no duplication of payments. As to the exclusivity of it, I am not sure that there is in the legislation that I have seen—and my colleagues can correct me—any prohibition against pursuing damages not covered in another forum. Certainly, if you have an administrative remedy set up for one purpose and another set up for a slightly different purpose, I see nothing wrong with pursuing your full damages in both.

Mr. Shaw. Would anyone else care to comment?

Mr. Connally. I think this is an area where I might disagree with Mr. Hackney. At least with regard to the tier 1 administrative remedies, my hope would be the Federal law would be structured in such a way that there would be an incentive for the States to take advantage of it with some type of matching formula. I believe the study groups recommend 80 percent/20 percent. That would effectively preempt the tier 1 or administrative remedies available at the State level.

As to the tier 2, general liability recovery, then I would agree with Mr. Hackney. It may well have been this is what he was speaking to; that the option as to which one to utilize in terms of the Federal or State remedy should be left to the party, as we do now with a variety of tort laws.

Mr. Shaw. You made the statement, Ms. Long, that the Federal fund would be administered by the State. How exactly would that work, and how would it be funded?

Ms. Long. I think there are several proposals before you now which would entail situations similar to that. I believe there is one proposal which has the Social Security Administration, through the State offices, administering the fund. But I think certainly for purposes of convenience, rather than an administration at the top with claims to be filed in Washington, some sort of State administration would make the most sense.

I certainly don't have any specific details. I think there are a number of mechanisms that could apply.

Mr. Shaw. But you are not necessarily advocating any one particular——

Ms. Long. No, sir; I am not.

Mr. Shaw. Mr. Connally, I have one more question I would like to address to you. You spoke of the California fund containing some $2 million, and to date no one has been successful in tapping that particular fund.

How about your tort law? Is it the same situation with regard to tort cases in the State of California?

Mr. Connally. There have been a number of successful recoveries under tort theories, product liability theories, under kind of a modified strict liability theory. The law in California is still emerging in that area. The *Sindel* case in particular, which involves the concept of applying strict liability and then apportioning the damages as opposed to the joint and several liability theory, appears to be applicable to hazardous waste, but that case has not gotten to the State supreme court yet.

So I think the best way to answer your question is, yes, people are recovering. The courts are moving in the direction of the Minnesota law and North Carolina law with regard to strict liability. We are not there yet. It appears, based upon early court cases, that it will be a strict liability with some type of apportionment or di minimis kickout, as opposed to a joint and several liability, as I understand is contained in the North Carolina law.

Mr. SHAW. The litigant would, of course, have the same problem of proof in a tort case, I assume, under California law as he would have in pursuing an action against the fund.

How do you account for the fact that there have been successful tort cases, but not in the instance of the fund?

Mr. CONNALLY. Very easily. In successful tort cases, you have people that have suffered unbelievably horrible damages—mutations at time of birth, death, permanent physical disability. So that the private attorneys representing those parties can make a hard economic decision that it is worth spending the money to make that epidemiological connection and prove that causal link.

The problem is with the smaller person, the person who has suffered damages maybe even requiring hospitalization, but for a very short period of time, that does not justify the expenditure of $50,000, $75,000, even $100,000 in terms of expert work to prove the individual causal link for that comparatively minor damage.

So it can be done. It is just not cost-efficient for the individual claimant.

Mr. SHAW. Under your tort law, I would assume those type of fees would be recoverable as part of the judgment.

Is that also covered under an action against the fund?

Mr. CONNALLY. No. Under California tort law, that is not recoverable as a separate additional charge. That is part of the recovery as a whole. It is not quantifiable in terms of the medical cost recovered. It is expertise. And that comes out of the judgment award.

For example, if you suffer $1 million in damages as a result of a toxic exposure, and it takes $100,000 to prove a causal connection between that damage and the toxic you were exposed to, you will get a $1 million award. You will have to pay the $100,000 in cost. If you suffer $10,000 in medical damages as a result of the toxic exposure, you can prove that, as well, for $100,000; but that would take the $10,000 that you recover plus another $90,000 out of your own pocket. So no one does it.

That, of course, explains why the two-tier concept, the administrative concept, where hopefully with a smaller level of proof using the rebuttable presumptions, will allow an effective recovery for the person who is injured, but not injured to the degree that justifies this inordinate expenditure of expert fee and research money to prove that causal connection.

Mr. SHAW. Do you think that part of the problem in pursuing the fund would be overcome if the California Assembly was to provide for recovery of expert witness fees, things of this nature, in actions against the fund? I assume that would not go as far as rebuttable presumption but would go a long way toward curing some of the problems in pursuing a cause of action against the fund.

Mr. CONNALLY. That is true. But what is the rationale that says if people bring a $2,000 lawsuit and prevail, that they can recover the full cost of the expert witnesses, when as a practical matter the overwhelming evidence is that those expert witnesses' costs are going to be $75,000 or $100,000? As a matter of public policy, at some point that doesn't make sense.

Mr. SHAW. Excuse me. I said I was going to ask the last question about five questions ago. I am somewhat intrigued by this line of questioning.

Wouldn't you, as an attorney representing someone against the fund, still want to go in loaded for bear with regard to what you are going to do with expert witnesses in case they do rebut your presumption?

Mr. CONNALLY. If we had the rebuttable presumptions, if we could prove it existed, if we could prove exposure, if we could take under the 301(e) language the study that shows that the client is suffering the kind of harm that one would anticipate when being exposed to this, we can go with that. If they come back and rebut our presumption, we will know that in a timely enough fashion that we can deal with that on an individual basis.

The practical reality is that most of those assumptions aren't going to be rebutted because the practical reality is that if the person is suffering the medical symptoms expected to be suffered when exposed to a toxic substance and were in fact so exposed, they are in fact suffering as the law anticipates they will from that exposure. So that although that option to rebut the assumption is there, only in a very small minority of cases would it be exercised.

Mr. SHAW. Thank you.

Mr. CONNALLY. I will just tell you, as a private attorney who practiced not in this area but in other areas involving presumptions, you prepare entirely different in terms of the expenditure of funds, expert witnesses, medical examinations and so forth when you have the benefit of the presumption as opposed to when you do not.

Mr. SHAW. I can understand that. But I know, having practiced law myself, that you always have the possibility that you have to be very concerned that someone is going to rebut that presumption. Then you are going to be looking at a Monday morning quarterback telling you how you should have done your case, which opens up a whole new area of tort law which those of us in practice have to be concerned about, also.

I thank you, Mr. Chairman.

Mr. CONNALLY. Thank you, sir.

Mr. ROWLAND [presiding]. Thank you, Mr. Shaw.

Can you tell me what experience you have had in your State thus far with the laws you now have in place with reference to the number of claims that have been filed? Do you have any information on that?

Mr. HACKNEY. Mr. Chairman, we do not. First of all, the legislation I have discussed here this morning has not been enacted. It has passed only one house.

So to back up and answer the underlying question of how we are doing with our existing tort law, my answer would be somewhat the same as Mr. Connally's—not very well. That is, there are lots of small claims that are going uncompensated because of the costs of prosecuting the actions. With or without the benefit of presumptions, that is going to be somewhat true, because the burden of proof with the aid of these presumptions, as I understand them, as explained by Mr. Connally, and the burden of proof that the plaintiff has in getting to the jury in my State, are not all that different. If you have to prove the existence of the injury, exposure, and that harm usually follows, you have a burden of proof—let there be no mistake about that—even if you have to do it in an administrative hearing.

So the only experience in our State which has caught the public imagination and which, I guess, is one of the reasons we are moving in this area, is that a transformer company took a truck out in the middle of the night and spread PCB's—polychlorinated biphenyls, I think that is—along the roadsides of several counties, including one in my district. People were pretty upset about that. That is one of those things where, as one of the other witnesses said, you can't prove any specific injury right now—maybe it was Congressman Young speaking of dioxins.

But that was cleaned up. There was a civil action brought by the State under the Federal legislation in Federal court for the cleanup costs. But that is all that I would report.

Mr. ROWLAND. Let me ask you, in that respect, if the legislation does become law in North Carolina, what sort of initial experience do you anticipate with reference to the number of claims?

Mr. HACKNEY. I don't think there will be very many. I think that industry is by and large doing a much better job in light of the glare of publicity that exists in this area.

I think we have a problem with cleanups. I think we have made a great deal of improvement in the way hazardous wastes are now being handled. We have a way to go, but certainly great improvement has been made. Those hazardous waste occurrences, as they are labeled in our legislation, which would result in personal injuries, would not be of great numbers.

Mr. ROWLAND. Thank you. Let me ask Ms. Long, then you have had your law in place since May 10 of last year; is that correct? You said the Governor signed it?

Ms. LONG. Mr. Chairman, the effective date was July 1 of this year, 1983. So it is a short history. As I have mentioned, in the area of personal injury and economic loss there has been only one suit. That was a suit already underway. And they are requesting that a count be added under the new law. The judge hasn't ruled on it yet.

Mr. ROWLAND. Mr. Connally?

Mr. CONNALLY. Under the tier 2 or general liability theories that exist everywhere, there are a large number of claims that are filed in California, always characterized by substantial major injuries. I can't give you an exact number—I would guess 100 a year. That is very much arbitrary.

With regard to the tier 1 administrative claim procedure, which became effective January 1, 1982, we have had two claims filed. We are receiving literally 30 inquiries a day. We will get 30 inquiries at the Board of Equalization in the State of California today about how to file claims. But as people learn about the proof standard which exists in the present California law, they are deterred and they don't file claims.

I would agree generally with what Mr. Hackney says. I think on the whole the number of claims, particularly after the tail is taken care of, will be much smaller than we fear. It may be in the area of—in a State the size of California we are talking about 500, 600 claims a year; not a very large number.

Mr. ROWLAND. Thank you.

Mr. CONNALLY. That is a guesstimate, Mr. Rowland.

Mr. ROWLAND. If we do enact legislation on a Federal level, special tort liability, you don't then perceive a large number of frivolous claims being filed?

Mr. CONNALLY. I would say no. Whether you have a strict liability theory or not, there is a threshold cost of about $5,000 to go to a courthouse and file a claim. So if you oppose the strict liability theory, individual attorneys are going to impose an evaluation as to the likelihood of success, character of the damages, before they file that claim. And they will, better than anyone else, sift out the credible from the noncredible with rare exception.

Mr. ROWLAND. Are you saying the attorney will absorb the expense of that filing?

Mr. CONNALLY. That is right. The attorney will, at least in California practice, absorb the cost of prosecuting that lawsuit and will not recover unless he or she is successful with that lawsuit. So that there is an initial threshold evaluation made by the attorney whether or not the claim is successful.

The difference between the negligent theory and strict liability theory is that the strict liability will give the attorney a better chance to be successful because he or she will be better able to prove that causal connection. So there will be a larger number of claims. But it is not a "Katie, bar the door; here they come," because there is still that initial threshold cost which is substantial enough to deter the nonserious person; incidentally, also argues for the continued existence of some type of administrative relief procedure for the smaller claimant.

Mr. ROWLAND. Mr. Hackney?

Mr. HACKNEY. I would certainly agree with that. I think one of the reasons we don't have many claims is that the contingent fee system we have requires that a lawyer bringing an action in North Carolina for negligence arising from some sort of toxic tort has a terrible row to hoe. I mean, the burdens of proof are almost insurmountable at this point. And so the cases simply are not being brought, particularly if they are smaller ones. They are going to remain expensive. But with a strict liability standard the risk would be taken in more cases.

Mr. ROWLAND. That is my point, I guess. If the strict liability standard is included, will this open the door for many more claims?

Mr. HACKNEY. For more claims from smaller claimants, is the way I would answer it.

Mr. ROWLAND. You don't perceive frivolous claims being filed then in this event?

Mr. HACKNEY. I would agree with Mr. Connally. I think frivolous claims are by and large filtered out, at least in our State. I can only speak from our experience. But we have not had a problem with that in any area of the law.

Ms. LONG. Mr. Chairman, I would agree. Minnesota basically has the contingency fee situation. Again, I don't think an attorney is likely to take a frivolous case and invest his time at a small possibility of being recompensed.

Mr. ROWLAND. Let me ask you something else: We heard in testimony previously, with reference to dioxin specifically—and we have touched on this some this morning—that we are not even sure what dioxin does. It is still undetermined.

What is your feeling about, for example, a chemical such as dioxin and how it relates to the claims that would be undertaken by attorneys as far as filing suits is concerned?

Have I made my question clear?

Mr. CONNALLY. I think so. And in the area of rebuttable presumption, for example, if there is not general medical evidence supporting the fact that a medical symptom arises from exposure to dioxin, the claimant would not have the benefit of the rebuttable presumption in that particular instance. That speaks, it seems to me, very powerfully to the point Ms. Long made, that the Federal Government, more than the States, more than the individual claimants, have to accumulate and publish a body of knowledge that shows where this causal connection exists on an individual basis by toxic substance, which then can benefit claimants throughout the country.

I would not—and I don't think any court would find or hold the benefit of a rebuttable presumption in the absence of, at least on a general basis, a causal connection between that substance and medical harm.

I am not sure I was responsive to your question.

Mr. ROWLAND. Yes, you were.

Mr. HACKNEY. I would just say that I practice law, as well, Mr. Rowland, and I wouldn't take one. It is just too much of an undertaking. And there is not that body of scientific evidence, it is my understanding, built up to allow an individual attorney, at least one in a small town, to take a case and be successful with it in an economical way.

Mr. ROWLAND. Mr. Wise?

Mr. WISE. No questions.

Mr. ROWLAND. I want to thank the panel for being here this morning and certainly providing us with a lot of information—it has been so helpful—in a very controversial area.

I think at this time the subcommittee will recess until 1:30, and come back at that time. Thank you.

[Whereupon, at 11:47 a.m., the subcommittee recessed, to reconvene at 1:30 p.m., the same day.]

AFTERNOON SESSION—1:30 P.M.

Mr. LEVITAS. The subcommittee will please come to order.

This is a continuation of today's subcommittee's hearings on the subject of victims' compensation. The witness this afternoon is Mr.

J. Paul McGrath, Assistant Attorney General of the Civil Division of the U.S. Department of Justice, who will discuss with us the position of the Justice Department and the Administration with respect to the matter of victims' compensation, toxic tort and the like.

Mr. McGrath, we welcome you. We are most interested in your testimony today. You may proceed as you so desire.

TESTIMONY OF J. PAUL McGRATH, ASSISTANT ATTORNEY GENERAL, CIVIL DIVISION, U.S. DEPARTMENT OF JUSTICE

Mr. McGRATH. Thank you very much, Mr. Chairman.

Mr. Chairman, I have submitted a written statement. I hope that that can be put in the record.

Mr. LEVITAS. Without objection, your entire statement will be made a part of the record.

[The statement of Mr. McGrath follows:]

STATEMENT OF J. PAUL McGRATH, ASSISTANT ATTORNEY GENERAL, CIVIL DIVISION, DEPARTMENT OF JUSTICE

I appreciate having the opportunity to testify on compensation for people harmed by exposure to toxic substances. The issue raised at this hearing is an extremely important one. For the last several decades we have placed a great strain on our tort system to resolve health-related claims, and now questions about the future of this system are being raised on all sides. Many have asked whether our current litigation and claims processes are working efficiently and cost-effectively. They have also asked whether sensible alternative schemes to litigation can be developed, and if they can be developed, whether they can be financed. And social scientists and other thinkers are asking where all this fits into our economic and social priorities.

We realize that the forces at work raise very difficult questions about whether the current system can survive without substantial change. The following are a few of the current trends:

1. The last decade has brought an explosion of knowledge about the causes or supposed causes of cancer and other serious diseases. Today it is possible to point a scientific, or at least a quasi-scientific, finger of suspicion at various substances for literally millions of cases of disease, although difficult questions of causation remain in the bulk of individual cases.

2. The last decade has brought an explosion of litigation, with more and better-financed attorneys and support personnel pointing toward an even-larger flood of litigation in the future.

3. The courts have greatly expanded the rights of claimants, liberalizing traditional rules concerning fault, knowledge, causation and injury.

These and other factors have created unprecedented numbers of claims against companies in many industries, seeking enormous dollar recoveries. In some cases the potential claims greatly exceed the assets of the defendant companies. In addition, it is no secret that the federal government also is faced with enormous potential liabilities in litigation.

All this raises the question whether our current tort and compensation systems can indeed cope. There is concern that these systems will not adequately compensate significantly injured victims of toxic torts. There is concern that defendant companies in some industries may face bankruptcy in unprecedented numbers. There is concern that the public Treasury may be subjected to enormous liability, perhaps diverting resources from other social programs. There is concern that the combined political pressure from all this may result in premature and inappropriate legislative solutions that we and our children may live to regret.

All this has presented this Administration with a host of difficult and unanswered questions which have led us to establish an interagency coordinating mechanism in an effort to do the best job we can to analyze and develop solutions in the area of toxic and environmental torts. This Toxic Torts Working Group is under the co-chairmanship of Michael Horowitz, Counsel to the Director of OMB, and myself, and it includes representatives from many agencies in the Executive Branch. Compensation issues involve many different agencies within the government: HHS because of its experience with administering income maintenance systems and medical care programs; EPA because of its environmental expertise; Labor because of its knowledge of workers compensation systems and occupational diseases; OMB because of its expertise in fiscal and budgetary matters; Justice because of the need for extensive legal analysis and to assess implications posed for the legal system as a whole; Treasury and the Council of Economic Advisors because of the economic considerations and the Office of Science and Technology Policy because of the broad scientific issues involved. The mandate of this group is very broad but relatively specific. We are not concerned with specific regulatory standards or controls in the management of toxic substances. Rather, our principal goal is to coordinate the government's analysis of proposed legislative means of alleviating toxic and environmental tort problems. Our mandate, put most simply, is to pull together the most complete information possible about the problems, to undertake the best analyses of different possible legislative solutions and to seek the best results for the country as a whole.

To date, our work is still at a preliminary stage. Different subcommittees of our group have been doing studies on various areas of significance, including analysis of legislation already proposed; studies of the environmental and toxic problems involved; a focus on the litigative realities and the ability of our torts system to handle them; an inquiry into what history teaches us, including the troubling lessons of the black lung program; and a compilation of information on what existing compensation programs are accomplishing. A number of people are involved in this work, and it is proceeding quickly. Even though we are still at a relatively early stage, a few observations can be made which suggest the complexity of this problem.

First, one of the things we recognized at the outset is that this is a broad problem which must be considered, analyzed and addressed in a comprehensive manner. In the past, various areas of toxic and environmental torts or injury have been dealt with on a piecemeal basis. There have been proposals to amend the hazardous waste statutes to deal with injuries from toxic waste sites. There have been separate proposals concerning asbestos-related illnesses, radiation-caused cancers, Agent Orange contamination and uranium mining diseases, to name a few. Some of the proposals do not appropriately recognize the difference between workplace and nonworkplace exposure. For the most part, these proposals have been considered in relative isolation from each other. We have come to recognize that this kind of disjointed consideration of what are economically, socially and politically related topics makes no sense.

The fact is each day there is a growing recognition of an expanding range of environmental problems which may have potentially injurious effects on individuals and which result in pressure for legislative solutions. Yet adopting fragmented solutions raises problems of fairness to claimants not covered or those denied other benefits because of the resources devoted to particular compensation schemes, as well as issues of society's priorities and the scientific uncertainty regarding the causation of a particular disease. If we were to adopt a governmental solution for some of these problems but not others, disfavored claimants could properly charge that they had been treated unfairly. On the other hand, when we look at the whole range of problems as an amalgam, we recognize that financially and administratively an overall solution raises very extreme resource allocation issues.

A second general point is a further development of the fairness issue I raised earlier. The current push is for special solutions for those individuals suffering from cancer or other maladies where we have isolated or think we may have isolated a cause of the disease. Those victims of diseases, however, are only a fraction of people similarly afflicted. No doubt a high percentage of others suffer from similar diseases, although we may only discover the cause of their disease in the future or we may never discover it. One might question whether it is fair to have a special compensation scheme for individuals who happen to suffer cancer from an identifiable cause, or one thought to be identifiable, but not for those suffering the identical disease where we have not yet identified the cause. Under the torts system such a result arguably makes equitable sense because the "wrongdoer" will pay. Under many of the schemes proposed as legislative solutions however, there would be no specific or known "wrongdoer" initially footing the bill; rather, society would be funding the relief more broadly through taxation, fees, general revenues or increased product costs. We might also ask whether a government program might not remove any incentive for the party responsible for the exposure to correct conditions.

Third, any answer to these interrelated problems will require us to analyze, question and perhaps make alterations in our fundamental legal institutions and procedures. For example, for many decades the torts system has provided a fairly effective mechanism for compensating victims of environmental hazards, at least in a great number of cases. Recently, however, some have asserted that the torts system is an inefficient and ineffective means of compensating victims or of transferring funds. In support of this assertion, statistics have been compiled which show that a high percentage of the dollars expended in the asbestos cases have been paid not to victims but to lawyers and paralegals and others who are simply part of the compensation system. The statistics referred to may well be accurate, but before reaching too much of a firm conclusion on the basis of them, at least two additional questions should be considered. First, do the high costs of these cases simply reflect the fact that they are at a relatively early stage? It is a well-established fact that such litigation entails large upfront costs for computerizing documents and other background materials and otherwise preparing to defend massive litigation. Second, are the alternatives that have been proposed substantial improvements over the current situation, when all their costs and benefits are considered? This may well be a promising area for alternate schemes for private dispute resoluton. Indeed, I understand some private groups are investigating alternate dispute resolutions for some aspects of these cases.

A fourth point relates to the very difficult issue of causation. The standard of causation will, of course, determine whether the program compensates those who truly deserve compensation. A standard that is too narrow may leave many who deserve compensation uncompensated. A standard that is too broad or too vague will undoubtedly benefit someone, but may not compensate those whom a program is intended to compensate, may benefit many more than is justifiable and may undercompensate a core class of intended beneficiaries. Furthermore, any causation standard that is developed as part of a toxic substances compensation program will significantly affect the standard of causation used in other areas particularly in tort litigation and workers compensation. In addition, we need to ask how we can develop causation standards which do not compromise the integrity of the scientific and medical decisionmaking process—that will not force it into premature and speculative conclusion in a search for false certainty.

There are many other more specific questions that have to be considered in analyzing this issue. For example: what type of compensation should be awarded—only medical costs and lost earnings or should a program offer the full panoply of tort damages, including compensation for pain and suffering? Should a compensation program be structured as a regulatory tool or should it be used primarily for remedial purposes? How should a compensation program be funded? Should a program be administered on the federal or state level? How should changes in the compensation laws be related to other existing remedies? Should any compensation scheme be built on the tort system or should it be an administrative system with nonadverserial proceedings?

New legislation should be measured against remedies now available. The main bills now before Congress relating to compensation for exposure to toxic substances contain a number of possible alternatives to the current system. They vary in coverage, from bills that would cover workers and non-workers to those that would cover only non-workers. They vary greatly in administrative procedures and remedies, standards for liability, funding mechanisms, exclusivity of other remedies, court jurisdictions and review, and standards of causaton. In examining these schemes, we need to answer very specific questions about their relative benefits, their other costs over time, the extent to which they may duplicate presently available remedies, the extent to which they fairly allocate transfer payments in a manner consistent with acceptable societal goals and the extent to which any legislative program can be kept within sensible bounds over the furture.

The history of the last several decades teaches us two troubling lessons: income distribution schemes have proven very difficult to control, and many times the total costs of such programs have been vastly understated at the time of passage. The terrible object lesson in the toxic and environmental hazard area is the black lung program. The billions of dollars it has cost the taxpayers were not even hinted at by its proponents; indeed, if its true costs had been known from the outset, it is difficult to believe that it would ever have been enacted into law. In addition, the black lung program demonstrates the tendency to add beneficiaries to any income distribution program who seem similarly situated to the original beneficiaries, thus multiplying the program's costs. The cold, hard reality is that whatever genius is used to fashion new legislation, we know there is a dire risk that the original sensible scheme will be turned into an economic monster. That risk creates large budgetary and fiscal dangers. Perhaps even more important however, in an era of limited resources, it also threatens to reduce our future flexibility to deal with the other problems of our society.

This concern with constraints on our budget makes the creation of a federal cause of action for toxic torts attractive to some as the means for insuring compensation to victims. We should understand that it is not a "free" compensation system; by establishing a legal mechanism for the transfer of resources from one societal group to another, it operates no differently than a tax or regulatory scheme. Indeed, on the whole it would operate less efficiently than a tax system because of the large transaction costs arising out of litigation. In addition, we should recognize that these cases would further burden an already crowded federal court system. It may satisfy a desire for "fairness", but establishing a private cause of action is not a "free" good.

The Administration is firmly committed to responsible policymaking in this area. Given the extraordinary potential costs and the fundamental changes to our legal system that could be generated by compensation programs, it is imperative that policy not be driven by anecdotal information or vague and unproved assertions of need. The Toxic Tort Working Group is intended to help achieve this goal.

Mr. McGrath. I would simply like to touch on some of the points that seem to me of most significance.

First, obviously I am grateful for the committee's invitation to appear here this afternoon to share with you information about efforts of the executive branch to analyze the problems that this committee has spent so much time and effort in examining itself, and I hope that this is the beginning of a common effort among us to try to deal with some of the very complex but critical problems which this committee has been dealing with that concern, the well-being of so many Americans.

I would like to discuss two main subjects. First, I would like to describe the Cabinet council group that has been established, the toxic torts working group. I would like to discuss the purpose of this group, its structure, and what we are currently doing. Second, I would like to discuss some of the conclusions, albeit in some instances tentative conclusions, that we have reached to date.

First, the toxic torts working group. As the committee is well aware, a variety of forces are at work which raise substantial questions about whether our current institutions can adequately deal with injuries caused by manmade toxic and harmful environmental conditions. Some of these factors include an expansion of scientific knowledge which has given us much more information as to the causation of many diseases, a veritable explosion of litigation in this area; and a broadening of claimants' rights, which at the same time is accompanied by increasing concern that some claimants are not really able to establish their rights. In addition, serious concerns have been raised concerning the increased costs that all this entails, and difficulties it creates for the operation of our judicial and our claims systems.

But, in addition, from the executive branch's point of view, we were also very concerned about the increased potential costs of these problems to the Government. The Government is defendant, or a potential defendant, in thousands of lawsuits alleging billions of dollars of damages, and obviously that is of concern.

Second, a number of the proposed legislative solutions do appear to raise very important fiscal concerns that ought to be looked at, both from that point of view and also from the point of view of our overall priorities. Thus, with that background the toxic torts working group was established as a working group under the Cabinet Council on Legal Affairs, and it was given the job of analyzing possible legislative solutions to the problems that this committee has been discussing and the job of perhaps developing alternative legislative proposals as appropriate.

I am one of the cochairmen of that working group. The other one is Michael Horowitz, who is the counsel to the Director of the Office of Management and Budget. On the working group are representatives of all the relevant agencies, such as Labor, and HHS, and EPA, and a number of other ones.

I want to emphasize that our goal is to coordinate the approach of the executive branch to legislation, or to legislative-type solutions. We are not dealing with or passing on regulatory controls for toxic substances. That is not our mandate. Our mandate is in the legislative policy arena.

We are now really at the first stage. We are trying to pull together relevant information on this area. One of the things, of course, that we have found is not that there is a paucity of information, but there is a deluge of information.

The first thing we are trying to do is to sort out what is helpful from what is not helpful, and to do specific studies in areas where we have found that insufficient data exist. In particular, we are undertaking to analyze the legislative proposals that have been advanced to date. We are doing a study of the tort system and its adequacies or inadequacies in this field. We are undertaking a study of the extent to which victims of toxic or hazardous substances are actually being compensated under current programs. We are doing a study of the Black Lung Program and its experience. We are analyzing the 301(e) study, which of course was the subject of extensive testimony previously before this subcommittee.

We are doing other studies like that in an attempt to pull together, as it were, in an organized fashion, the kinds of background information we feel are necessary to make a contribution in this area. Obviously, our next step is to react to proposed legislative solutions, to develop alternatives, and to work with Congress as best we can in a cooperative fashion to see what we can accomplish in this area.

I would like to mention several preliminary conclusions that we have arrived at in the several months that we have been discussing some of these subjects. One is that we believe you really cannot consider the problems of compensating victims of toxic torts on a piecemeal basis. The general history in this area is for bills relating to different kinds of injury to be considered totally separately, frequently by quite different groups in the executive branch, different groups on the Hill. For instance, there would be a wholly separate set of hearings on asbestos and a wholly separate set of hearings on Superfund and so on.

But it is our view that whether or not there are separate considerations as to these individual problems—and, obviously, there are—nevertheless the area as a whole really needs to be considered as a whole. A reason for this is that there is an expanding recognition scientifically of what problems are caused from certain kinds of toxic substances and hazardous conditions. The kinds of considerations that go into what kinds of compensation schemes might be appropriate are essentially similar. The issues tend to be the same. Overall, when you consider the costs, the administrative concerns about different kinds of programs, the kinds of overall priorities that have to be considered are the same.

A related conclusion is that you come to a matter of fundamental fairness fairly early on in considering these problems. The legislative proposals that we have been dealing with by and large concern victims or people who may be victims of certain kinds of conditions, certain kinds of waste sites, certain kinds of industrial pollutants and the like. They concern victims or people who we believe may be victims where we think we know the cause. The problem, of course, is that those people are only a small fraction of the people who suffer from essentially the same disease, be it cancer or some other disease.

We undoubtedly will learn over the coming years of other groups who are similarly afflicted. But the problem is, we, through many of these compensation schemes, would only be compensating a small fraction of the people who have the same disease, who are suffering from the same ailments, and who perhaps may have indeed been inflicted by causes that are the same or essentially the same as those who would be compensated. Yet, we simply don't have enough scientific information to be sure that that is the case.

Now, singling out certain groups for compensation makes a good deal of sense if you are operating under a tort system in court, or before some kind of compensation board, because then the wrongdoer in the tort sense would compensate the victim. However, to the extent that you set up a compensation scheme where the wrongdoer in the tort sense is not providing the compensation, then what you are really doing is you are singling out certain people for special consideration. And there may be issues of fairness in doing that. Obviously, whether those conditions arise depends on the kind of scheme that is developed.

Third, in looking at our current compensation systems, and particularly our court system, our tort system, there are very difficult issues in analyzing how well the courts are doing. We have all read, with some horror, I think, some of the statistics that have come out of the asbestos litigation, for instance, which have dealt with what percentage of recoveries are going to preparation of litigation, lawyers' fees, and so on, as opposed to victims.

A problem with those statistics is that they may not really reflect the actual situation because those cases are at an early stage, and in that kind of litigation the expense of just getting geared up for the defense tends to be very heavily loaded at the front.

Now, I don't mention this as a critical factual issue. I mention it as the kind of difficult factual issue which we run into when we try to make a judgment as to how well the current system is running. I think we have got to look very carefully at the current system, what kind of a job it is doing, and make a reasoned comparison with the current system and any alternatives that are suggested.

The issue of causation leads me to a fourth general conclusion. I am sure I am not sharing any wisdom with the committee when I say that we have found just from the studies we have done to date that that issue is a very difficult one. The glib statements by some people that there is simply no causation relationship between toxic waste sites and toxic substances goes much too far, obviously. The assertions by others that there are all sorts of causation relationships that we have established really goes too far the other way.

We are advancing in our scientific knowledge all the time. But the issue of causation is very important because to the extent we accept very broad causation, that obviously expands almost geometrically the cost of any program, both in terms of compensation provided and in terms of the management of the program. And it also raises, again, issues of fundamental fairness, because whenever you are going to compensate certain groups of people, a preliminary issue is: Who is in that group? And we, I think, in any kind of a compensation scheme we are talking about here, cannot get away from the fact that the question of causation and the conclusions we reach as to causation will probably be very important in determining who is in whatever group will be compensated.

Finally, the last observation I have is that we are concerned that any legislative solution, however good a job we do in coming up with a legislative solution to any one of these problems, over time, will meet with changes that perhaps can so distort the program physically or in any other way that we may end up with something that we really didn't want at the beginning.

There is obviously no way that we, sitting here in 1983, can protect ourselves for all times. But it does seem to me that we have to be at least cognizant of the fact that whatever scheme we set up—for instance, however we define causation or whatever presumptions we may put into it, can be shifted ever so slightly so as to create a much more expensive or cumbersome scheme.

In my prepared remarks I did refer to the Black Lung Program as an example of a program where that happened. I don't mean really now to say that Black Lung Program was good, bad, or indifferent. It is simply that it was a program that became vastly more expensive than was originally assumed, and which changed over time through slight modifications in the presumptions as to causation which vastly expanded the class coverage.

I would like to say in closing that the hearings this committee has had to date have been very helpful to us. I have read what I believe to be all of the testimony, at least all the testimony I was given, that has been presented before the committee. It has been tremendously helpful to me personally. And I know a number of the others of us who have been working in this group have been reading it, because we are struggling with the same problems. We do very much appreciate the opportunity to participate in the process.

I again repeat, I hope this is only a beginning.

Mr. **Levitas**. Thank you very much, Mr. McGrath.

I think I can certainly agree with you that it is a problem that is so important and so complex that it will require the cooperative effort of everyone involved. I hope our hearings, as they continue, will shed some additional light on that.

I am only going to ask maybe one and one-half questions before I recognize the gentlewoman from Connecticut, and then get back to you later. Let me tell you what my main concern is with the Administration's position. Not that you have failed to identify the problems; I think you have.

What keeps coming back to my mind is: What are you going to do about it? When I say "you," I mean our Government. Right now, it is this administration. In a few years, it may be another administration. This problem is so tremendously important. It affects the lives of so many millions of people today, and in years and indeed generations to come, will continue to affect the lives of people.

My sense is that we cannot simply say—as a Government responsible for the well-being of this Nation—that the problem is so bad and difficult that we can't do anything about it except say how bad and difficult it is. I think we have a responsibility—we in Congress and whoever is in charge of the administration—to say this is a terribly difficult problem. We have got to do something about it, and that is not what I am hearing.

I have a copy of a memorandum dated May 19, 1983, entitled "Compensation for Toxic Substances Exposure," which I understand comes from OMB. Under Roman Numeral V, Superfund Compensation Commission Report, which I take it is the 301(e) Commission study report, the memo says, and I quote, "As part of the 1980 compromise, a commission was established to study compensation. The Commission's recommendations adopted the worst of both worlds, an administrative compensation system with liberal evidentiary standards and generous benefits as well as continued availability of traditional tort law."

The next comment is entitled "Open-Ended Fiscal Threat . . ." "Although its advocates," and I am quoting now, "price Superfund compensation proposals at only a few billion dollars,"—they did put "only" in quotation marks, as you would expect, "The amounts at stake are literally open-ended and potentially enormous. Given the ambiguity of Superfund, compensation could be provided for virtually any environmental exposure and not merely exposures directly related to waste disposal sites. Under the proposed compensation mechanisms, substantial amounts will go into lawyers' fees creating a strong incentive for increased litigation. For example, one-half to two-thirds of asbestos industry payouts go to lawyers' fees and litigation expenses."

Now, that is the end of what they said. Part of that is quite true. However, I think the problem and impact are more significant. If you read just what those few witnesses from Times Beach had to say, I don't think you could help but be impressed that we, sitting here in Washington, don't really appreciate the enormity of what happens to a person when his dreams are abolished and wiped out, along with his health, as well.

What are we going to do about it? How do you respond to the concerns expressed by the Office of Management and Budget? And, where do we go after having heard their fiscal comments?

Mr. McGRATH. I really don't want to respond directly to the conclusions of the 301(e) study today, because we still are in the process, and we are quite a ways along in the process, I might add, at the Justice Department of coming up with our view on that. But let me make this point. The 301(e) study proposals, in effect, would involve setting up a system which might, for instance, do one thing. It might provide for a compensation scheme which would reverse presumptions, and reverse the burden of proof.

The kind of thing that it can do is, for instance, if you have an area of the country, and it is alleged that a given toxic site increased the incidence of a given disease there, for example, some kind of cancer, it may result in a situation where everyone in that area who had that cancer could effectively recover from this compensation system. That could mean, for instance, that let us say the increase of that particular cancer in that area was 10 percent. Yet under this scheme 100 percent of the people who had cancer in that area might recover. Now, to be sure it is a beneficial thing in a sense that all those victims of cancer are compensated. It would be beneficial in many senses if all victims of cancer could be compensated. The problem is that under that kind of a scheme, you end up compensating certain people on the happenstance that they are in an area where you can show some incidence of increased cancer, whereas other people who are similarly situated, who probably got cancer from the same kinds of causes, are not compensated at all.

The additional problem is that to the extent you expand recovery to a vast number of people, the physical consequences can be so large that you have a real priority problem in this sense. Once it gets large enough it puts pressure on other programs, for instance, more pressure on programs that compensate the needy. And then we come up with a direct conflict between the ability to compensate, for instance, those victims of cancer who cannot afford housing, who cannot afford to pay for their education of their children and so on; you come up with a conflict between compensating them on the one hand, and on the other hand compensating people who happen to fit within certain classes.

One of the things that we are seriously considering is to what extent victims of toxic torts are compensated under current systems, for example, disability systems and so on. What are the loopholes in that system? What are the groups of victims who fall between the cracks and end up not only with disabling diseases but with a situation where they cannot cope financially with their problem? And one could argue that those are the people we ought to be primarily concerned about and not some group who are similarly afflicted with a disease but as to many of whom there may be suitable financial wherewithal to do the things that people need to do. Now that is a slightly different way of looking at this problem.

It does, however, turn on your priorities. If we had an unlimited amount of money to spend, that question would not get raised. But we don't.

Mr. LEVITAS. I agree with that. But let me say this. This is the other half of my question—I said one and a half—and then I'll recognize Mrs. Johnson. I have never handled a toxic tort lawsuit. I am not sure they had toxic torts when I was still practicing law. Whatever. The point that you make about overinclusion I suggest exists under the tort system as well. Because it would seem to me at least one of the ways a plaintiff's attorney would go about making the case that there is a causal effect between that hazardous waste site and the plaintiff's injury, physical condition, the cancer, is precisely what you have just described.

He would say all across the Nation the rate of cancer is 3 per 100, or 3 per 1,000. In this community it is 5 or 10, or whatever the increment is. And that, if accepted under the rules of evidence in that particular jurisdiction, might be the basis upon which a jury could conclude that this plaintiff or that class of plaintiffs are therefore all entitled to recovery. So even though that is a very intriguing logical argument, I don't think it argues against whether or not we need a two-tier system of the sort that the 301(e) Commission has proposed on the theory that we might be overincluding, because I suggest to you that that overinclusion, because of that type of epidemiological evidence, could occur even if we had the traditional tort system.

Mr. **McGrath**. It could, Mr. Chairman, but at least it is my view it should not. For example, in the Allen litigation in the district court in Utah, the downwind low-level radiation case, the legal issue you have just posed is probably the most important legal issue before the court at this time. And obviously, the argument we are making in the litigation is essentially the argument that I just advanced in connection with this legislation. And under traditional tort law, and under the tort law as we think it should evolve, I think the argument should come out the same way in the litigation.

I do want to add, what I am doing in the legislative arena is divorced from the litigating arena. It happens that I have responsibilities for the litigation. But if it seems right to come out some different way in the legislative thinking, then I will and we will. I just add that as a footnote. I am not here advancing our litigating interest.

Mr. **Levitas**. I understand that, and I certainly would not want you as an attorney to do anything that would jeopardize your position in some ongoing litigation. I only make that point to suggest to you that if that evidence gets to a jury, and if the jury in this case are the Members of Congress, I think, although I don't want to prejudge anybody's position on that, that is going to be considered too much of a nice lawyer's argument.

It is a good argument, but I think the question is, to the individual who suffered from cancer, why should I have to decide whether I would have gotten cancer any way if in fact I fall within that group that is at risk, because you are never going to find out. If the alternative is to compensate nobody, or to overcompensate, my guess is that whichever jury you are talking to, whether it is this jury here or that jury out there, it is going to say if we err we err on the side of the victim.

Mr. **McGrath**. I think I agree with you 100 percent, that the issue is very, very close to the same issue in either context. The countervailing consideration is that once we overinclude at a vast level, and I am not talking about just a few percentage points, I am talking about the situation that I referred to before, we may exhaust our resources. It is not a free good. In other words, once you do that you place a big financial burden on somebody.

It has been suggested that we place it on the industries in question. Obviously we can do that. But we have to recognize that if we do it in certain ways you will place such a big burden on them that perhaps the industry will not be viable anymore. For example, one of the things that I believe was referred to in that paper you quoted from before, is a proposal involving asbestos where the tax on the industry would have doubled or tripled the price of asbestos, obviously making it a product that simply couldn't be sold.

Now, all I am saying is that you have to look at the consequence. And I am sure you recognize this.

Mr. LEVITAS. I recognize that, Mr. McGrath. Although we sometimes lose sight of it, and I want to repeat it as often as necessary, I am convinced that we live in a society in which the quality of life has been vastly improved because of the utilization of chemicals. However, we now know of certain risks and hazards associated with them, and we are paying a price for that.

I also recognize the fact that we are going to continue to live in a society that produces hazardous waste. Our next agenda is going to be how do we eliminate or minimize the risks from it. But again, while I accept the fact that we have benefited from it, there is a cost and it cannot be loaded in such a way that we throw out the baby with the bath water.

Mrs. Johnson?

Mrs. JOHNSON. Thank you very much, Mr. Chairman.

Thank you, Mr. McGrath, for being with us today. First, just a couple of very specific and narrow questions. You referred to in your testimony to some preliminary conclusions. Could you give us some sense of timetable? For example, your analysis of the current programs and to what extent victims of toxic torts have been compensated under current programs. When do you expect that study to be completed?

Mr. MCGRATH. My hope is that at least the early stages of all these studies, or the initial studies, will be done before the end of this calendar year because our hope is that we really will have together a high percentage of what we want to have finished before the next session of Congress.

Now, it wasn't as if we set this up with that timing in mind. It is rather that the committee got set up this summer, and that is the way the work has been going. But I say preliminary studies because obviously the job of analyzing legislation will go on. When we get preliminary information on the extent to which current schemes are compensating people, presumably there will be more work that will be done.

But I really hope and our plan is that we would have the bulk, at least, of the early work we are doing done before the end of this calendar year. And I hope enough before that so that some of us really have a chance to sit down and think about where it leads us, what other things we ought to look at, and so on.

Mrs. JOHNSON. And hoping to be in a position to propose legislative remedies, if they are appropriate, by the beginning of the next session?

Mr. MCGRATH. By the next year, yes.

Mrs. JOHNSON. A second question. What is the role of EPA in your work?

Mr. MCGRATH. Well, EPA is represented on the working group. The General Counsel of EPA, Jim Barnes, is personally involved in our work. They are involved in helping us pull together some of the facts. We have split the working group's responsibility for each of these studies up so that the agencies who have particular knowledge are helping on particular areas. For instance, I believe EPA is one of the agencies that is assisting in the analysis of the legislative proposals that have been made, because obviously some of these proposals they have been directly involved in, but also they tend to have people who are more knowledgeable than in other areas.

There is no magic to the way we have split up the work. It has been an effort to have the agencies that have the expertise in a given area be involved in a given study.

Mrs. JOHNSON. If there is more than one subcommittee that affects very deeply EPA, does EPA then have somebody on each of the subcommittees?

Mr. MCGRATH. Yes.

Mrs. JOHNSON. To follow up on their work, yes?

Mr. MCGRATH. Yes.

Mrs. JOHNSON. In spite of the limit on their number on your overall council?

Mr. MCGRATH. That would be correct, yes. There are some agencies that are involved in a number of the studies, and other agencies that are involved in perhaps only one. For example, one of the things that we are doing is trying to come up with estimates on the costs of different programs. We have some representatives from the President's Council of Economic Advisers and the Treasury Department in the group. That obviously is the area that those people are involved in. They are not analyzing legislation or studying the Black Lung Program, or something like that. They are, hopefully, people who can help us come up with as good information as we can come up with on the costs of doing different things.

So that would be an example of some agencies that have a relatively narrower role. I don't want to say a minor role, because obviously that is an important consideration, whereas an agency like EPA or HHS or the Justice Department would be involved in several different areas that we are concerned about.

Mrs. JOHNSON. Thank you. Now, earlier in your statement you talked about the fact that causation is very difficult to determine. That it is critical to determining the eligible group, the compensatorily eligible group.

Mr. MCGRATH. Yes.

Mrs. JOHNSON. It seems to me, sitting on the Veterans Committee and on this committee, that indeed causation is very difficult to judge. And at this point, in terms of the amount of scientific information we have available to us, our ability to judge causation does vary dramatically from area to area. I find that conclusion from my experience in contradiction to your apparent assumption that you should be looking at this problem as one single great problem.

You mentioned earlier in your testimony that the issues are always the same. But where you don't have similar scientific data, are the issues the same, or are we even in a position to know if the issues are the same? And yet the availability of that data may make it possible still to deal, at least to some degree, with the compensation issue.

Recently we did, for instance, go part way in dealing with the agent orange issue—that portion of the problem that does seem to be fairly well documented. There were those who wanted to go beyond that.

These issues are very difficult. Causation is difficult. And it seems to me that that reality is in contrast to your approach, that the issues are fundamentally the same, and that they are all aspects of a single problem.

Mr. McGRATH. Well, I would not say that all the issues as to each of the individual substances are the same. For instance, obviously the issue as to what diseases agent orange or other forms of dioxin cause and in what circumstances they may cause them are quite different from the issues relating to low-level radiation or asbestos or benzene or other things. But for instance, there are overall policy issues for the Congress, for instance, which really are quite the some for each one of these. One of them is the issue that the chairman and I were discussing before. And another is the extent to which you require what I will call loosely "good" proof of causation before someone would be put into a class, and what is "good" proof of causation. Because I don't think that it is good policy to treat, let us say, victims of asbestos totally different from victims of benzene or hazardous waste sites.

It seems if we are talking about either using public funds or taxing industry groups, which in economic theory is really not much different, it is not good public policy to single out one group and say, okay, we will deal with agent orange victims or dioxin victims but we will forget about all these other people who for all intents and purposes are similarly situated.

Mrs. JOHNSON. But see that is the question. Are they similarly situated? To what extent? In other words, aren't we capable of actually dealing with all those groups where we do have enough data to be able to define causation? I think you are overdrawing the equity problem.

Mr. McGRATH. The problem is if we do that, let us say to take an extreme, in one of these areas we decide the thing to do is to set up a Federal compenstion scheme. I just mention this as the extreme example. We say all right, this year we have a pretty good lead on what victims of x substance, which people are victims of x substance. Well, if we say we will compensate them and then every other group that comes along where we have good causation proof we will simply expand the scheme to them, the chances are that over the next few years we will end up with an enormous program, for two reasons. One is that we have to assume that over the next few years we will learn more and more about this causation issue. Certainly we all hope we will. Second, by the nature of these programs there is at least a substantial risk that once one is set up the presumptions that will be made, the inclusions of people will be vastly expanded, the same way that they were in the Black Lung Program until just recently.

So that you have to really be very careful about saying, well, we will just deal with this part of the problem, because as a matter of political reality, fairness, whatever you want to call it, we are not likely to leave it there. And we may well create something that would be enormously expensive over time.

And if, indeed, over time we did not expand it to all the people who were similarly situated, you would have a very fundamental fairness issue. And that really, I think, gets to the heart of the concern that I have had. We all recognize that victims of toxic waste sites and harmful substances should be compensated if at all possible. But before we embark down a road where we are going to pick one way of doing that as opposed to another way of doing it, let us think very carefully about what is the goal gain that we are moving toward.

Mrs. JOHNSON. I think I generally agree with your concept. Though I don't agree with the way that you have phrased it earlier in your testimony. I think that as we do know more, we have the ability to create compensation programs that are appropriate and reflective of our knowledge. And there would only be an equity issue if, in the future, people about whom we learn similar amounts were not included.

Mr. McGRATH. But you would not even have an equity issue, for instance, if it were approached from certain other directions. For example, there are ways to foster effective use of private insurance, both to permit the, say the industry in question or the toxic site in question, to actually provide the compensation where they have caused the damage, and also to permit people in industries to have insurance to cover disability.

There are ways of making sure that our existing disability and other programs cover people who may become disabled so that the basic expenses of life can be dealt with. There are various ways to compensate people. And when I said that we all agree that there should be compensation available for the kinds of victims we are talking about, I don't necessarily assume that that scheme need be a Government-funded or run compensation scheme or that it ought to involve the creation of new presumptions or other rules of Federal tort law.

There are other ways to go at the problem, and that it seems to me ought to be a focus. Let us not just assume that we are going to create another entitlement program. Let us look at the whole range of ways that we can deal with this, because this is a problem that is going to be with us for a long, long time. It is going to become an expanding problem. And let us at least try to do the best we can at the beginning, not to create something we will regret.

Mrs. JOHNSON. I would certainly agree that compensation is the issue. And publicly financed compensation is not the only approach to that issue. And I think you recognize that by looking at the current programs and current systems to see how indeed compensation for disability is now being achieved or granted.

That leads me to my last question, and that is, your use of the word entitlement. In my estimation entitlement and compensation are two really very different things. And the word entitlement right now, at least in our society, really implies a much broader eligibility. You are entitled to Social Security simply by virtue of having contributed, whereas compensation implies much more specific—an assumption of injury. I think it is unwise to confuse those two concepts in a program like this.

What we are really talking about here, in my estimation, is compensation, not entitlement.

Mr. McGRATH. I agree with that. An entitlement program is one sort of a compensation program, but only one sort. In other words, an entitlement program could be set up here. Congress could pass an authorization bill which authorized, and indeed required, the payment of money to any individual who could establish a certain disability that he or she lived in a certain area, whatever. That would be an entitlement program. I am not suggesting that one should be created. Indeed I am suggesting we ought to think long and hard before we create one.

Compensation, however, covers a whole range of things from there all the way over to programs which encourage people to have private disability insurance, or corporate group disability insurance.

Mrs. Johnson. Thank you.

Mr. Chairman, that concludes my questions at this point.

Mr. Levitas. Thank you, Mrs. Johnson.

I thought the last point that Congresswoman Johnson made is extremely important, and I am glad it came out the way it did. In response to her observation, you said that you do understand and appreciate the difference between compensation and entitlement. My question to you is, based on your dealings with OMB, does OMB understand the difference?

Mr. McGrath. I believe so. Certainly in the sense that I have described the difference and in the sense that I believe this committee is considering the two. Just from having read as much as I could of the proceedings here, I have understood you to be really considering the whole range of options and issues and so on. So I assume the answer to your question is yes.

Mr. Levitas. Well——

Mr. McGrath. At least speaking for the people we are really focusing on.

Mr. Levitas. The reason I say that is because we are considering the whole range. We are not prejudging or eliminating in advance any option that is available to us. But there is clearly a difference between our compensatory system, like workmen's compensation, for example, on the one hand and entitlement systems, disability under Social Security, on the other. If you put those together you are going to make some wrong judgments about where you are going to come out.

The reason I mention that is as I read this infamous OMB memo of May of this year I don't come away with a great deal of comfort that somebody is really looking for a solution within the context of the leadership which the administration should be providing. I get a very negative feeling about it. I get the idea that they think there are a lot of unrepresentative horror stories upon which Congress is about to respond, and create some unaffordable system without the positive feeling that I would like to come away with and say, yes, we have got a problem.

We have got to find a solution. We have got to look at a lot of different alternatives, but the bottom line is we have got to find a solution to that problem and not simply to say the people who suffer: "suffer."

Mr. McGrath. All I can say is that I do—my approach is the latter and a lot of what you see and what you have read is in part our effort to get the executive branch thinking about this whole thing. As you have seen from that document and some other ones that have been published, the main goal of this working group was to try to get the different parts of the executive branch that have knowledge, that have ability, working together on this thing. And the only way you get that done is to really do something that gets everybody's attention. And about the only thing that really gets that attention sufficiently is to talk about costs and talk about overall fiscal concerns.

I hope we can go from there to be constructive, to work constructively. I believe we can. I don't really have any doubt that we can.

Mr. LEVITAS. Let me ask you this: is the Federal Government a defendant in any pending hazardous waste litigation now?

Mr. McGRATH. I don't know the answer to that, Mr. Chairman.

Mr. LEVITAS. Would you find out and supply it for the record?

Mr. McGRATH. I will supply that for the record.

[The information received from Mr. McGrath follows:]

COMMENTS ______

Honorable Elliott H. Levitas
Chairman
Subcommittee on Investigations & Oversight
Committee on Public Works & Transportation
Rm. B-376, Rayburn HOB, S.W.
Washington, D.C.

Re: Request for Information Concerning Hazardous Waste Litigation, Hearings of November 8, 1983

Dear Mr. Chairman:

It is my understanding that, during the testimony of Mr. J. Paul McGrath, Assistant Attorney General for the Civil Division, before the Subcommittee on November 8, 1983, a request was made that the Subcommittee be provided with information concerning the number of pending actions in which an agency of the United States is allegedly liable for cleanup costs or damages relating to a hazardous waste site or facility.

To assist you in your deliberations, I have informally requested an inventory of actions under the Resource Conservation and Recovery Act (RCRA) and the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) in which federal agencies have been alleged to be liable in some way for hazardous wastes. A list of those actions and a short description of the case, its status, and the nature of the allegations against the United States is attached as Appendix I. Most of these suits were originally initiated by the United States and involve counterclaims commonly alleging relatively small contribution to the problem by a federal agency. The list does not include suits under the Clean Water Act or other environmental statutes which may involve hazardous wastes but which are not "hazardous waste suits" as that phrase is commonly used.

We are particularly pleased with the progress being made to resolve City and County of Denver v. Ruckelshaus, et al., D. Colo., Civ. 83-1043, where a consent order has been negotiated and submitted to the governing body of Denver for its approval, by which Denver would initiate a response at the subject site,

Shirley-File pls.
Jack

while reserving any rights it may have to seek participation by or compensation from others. A settlement has not been fully negotiated, but progress to date reflects our ability to deal with special circumstances presented by hazardous sites which may involve federal agencies. It continues to be this Administration's firm policy that federal facilities have a strong obligation to set an example in meeting the standards which both RCRA and CERCLA impose upon private facilities and the Administration will continue to make every effort to see that federal facilities set such an example. This Department and EPA have been quite successful in receiving contributions from federal agencies toward the cleanup of several hazardous waste sites where multiple generators were involved.

Thus far, the United States has not taken a formal, written position regarding its legal status as a potential defendant in hazardous waste suits.

Please let me know if you desire other information concerning the listed cases or other cases. Within the limitations imposed by the conduct of litigation, I will be pleased to assist you in any way possible.

Sincerely,

F. Henry Habicht, II
Assistant Attorney General
Land and Natural Resources Division

APPENDIX I */

City and County of Denver v. Ruckelshaus, et al., D. Colo., Civ. 83-1043:

This action was filed June 10, 1983 against numerous federal and state agencies and officials and private corporations, and involves the "Lowry landfill," which is owned and operated by Denver. The action is in response to a CERCLA Section 106 administrative order issued against Denver on June 8, 1983, ordering it to take certain response actions at the site. The suit seeks declaratory and injunctive relief to prevent enforcement of the order, asserting that the United States and others are also legally responsible for conditions and should be compelled to share in costs associated with compliance. The United States has moved to dismiss the complaint and is conducting negotiations with Denver and others, with the objective of settlement. A consent order has been negotiated and presented to the Denver governing body for approval, by which Denver would begin a response, while reserving any rights it may have to seek the participation of or compensation from others. The action is pending.

Florida v. Silvex, et al., M.D. Fla. Civ. 83-926-CIV-J-14:

An action was filed against the United States in state court, under state hazardous waste laws similar to CERCLA. The action has been removed to federal court on a motion by the United States. The United States has moved for dismissal of the suit on grounds of sovereign immunity. The Navy is alleged to have sent wastes to the site which were released and have damaged natural resources. Florida is seeking natural resource damages and a response. The action is pending.

---

*/ Several actions which may involve allegations against the United States were filed around the nation between December 9th and 12th, 1983, due to a CERCLA statute of limitation. To the best of our knowledge this list is accurate as of close of business December 12, 1983.

United States v. Chem-Dyne Corp., et al., S.D. Ohio, Civ. C-1-82-840

This action was initiated by the United States under various provisions of RCRA and CERCLA to obtain abatement of an endangerment to health and the environment and for other relief. Some defendants have counterclaimed against the United States, alleging that it used the site and encouraged others to use the site. The United States has admitted use of the site, but declined to respond to allegations of liability, which are legal and not factual in nature. The action is pending.

United States v. Columbia Steel and Metal, et al., D.S.C., Civ. 83-1487-0:

This action was initiated by the United States under various provisions of RCRA and CERCLA to obtain abatement of an endangerment to health and the environment and for other relief. Some defendants have counterclaimed, alleging that the United States generated wastes which were disposed of at the site. The United States has acknowledged that 12 of 550 drums of waste located at the site are marked "EPA", but has declined to respond to allegations of liability, which are legal and not factual in nature. The action is pending.

United States v. South Carolina Recycling and Disposal, Inc., et al., D. S.C., Civ. 80-1274-6

This action was initiated by the United States under various provisions of RCRA, and amended to include allegations under CERCLA, to obtain abatement of an endangerment to health and the environment and for other relief. Some defendants have counterclaimed, alleging that the United States generated some wastes which reached the site and exercised regulatory control over the site. The United States had admitted that some of its wastes went to the site, but has declined to respond to allegations of liability, which are legal and not factual in nature.

United States v. J. B. Stringfellow, Jr., et al., C.D. Cal., Civ. 83-2501(MML)(Mcx):

This action was initiated by the United States under various provisions of RCRA and CERCLA to obtain abatement of an endangerment to health and the environment and for other relief. Three defendants have counterclaimed against the United States, alleging its responsibility as a generator of certain wastes. The action is pending.

United States v. Wade, et al., E.D. Pa., Civ. 79-1426:

This action was initiated by the United States under various provisions of RCRA, and amended to include allegations under CERCLA, to obtain abatement of an endangerment to health and the environment and for other relief. Some defendants counterclaimed, alleging that wastes of the United States were disposed of at the site. The United States has answered, denying that any of its wastes went to the site. The action is pending.

State of New York v. U.S. et al., E.D.N.Y., Civ. No. 82-2228:

This action was filed in the summer of 1982 against the United States. It involves groundwater contamination by jet fuel in Suffolk County, Long Island at Westhampton Air Force Base. In its initial complaint, the State of New York sought injunctive relief and damages on a variety of theories under the Clean Water Act, Federal Tort Claims Act and common law doctrines. We have learned that they are now moving to amend their complaint to include a CERCLA Section 107 claim for natural resources damages for an amount which is presently unknown but probably will be $50 million, estimated response cost. The action is pending.

U.S. v. Shell Oil Company, D. Colo., Civ. No. :

This action was initiated by the United States for recovery of response costs and damages to natural resources at the Rocky Mountain Arsenal, Denver, Colorado under Sections 104 and 107 of CERCLA and for damages and injunctive relief for breach of contract, restitution, and tort, and for a declaratory judgment on December 9, 1983. The State of Colorado served the Department of the Army with a claim under Section 107 and 112 of CERCLA for natural resources damages at the same site on December 2, 1983 and filed a complaint in the Colorado District Court on December 9, 1983. The action is pending.

New York v. U.S. (Solvent Savers), N.D.N.Y., Civ. No. :

This case was filed on December 9, 1983. The State of New York is suing the Air Force as a generator under CERCLA, for response costs and natural resource damage claims arising out of activities at Griffiss Air Force Base in Syracuse. The action is pending.

Cadillac Fairview/California v. Shell Oil Co., Ruckelshaus et al., C.D. Calif., No. :

This action was filed on December 9, 1983 against Shell Oil Company, Dow and the United States. Cadillac Fairview is seeking a declaration that GSA, as successor in interest to two defunct federal agencies, is liable under Section 107 of CERCLA for response costs for removal of hazardous wastes, and an injunction requiring EPA to undertake further remedial action at the site. The action is pending.

United States v. Saul Levy, et al., W.D. Wash., Civ. No. :

The United States initiated this suit seeking hazardous waste cleanup and other relief. The defendant, site operator has counterclaimed alleging that the United States sold surplus substances to him. The action is pending.

Mr. LEVITAS. I see, obviously, the potential of that occurring. Let's take a certain DOD site in a southwestern State which has been recently found, and contrary to earlier hopes that it was not penetrating through an impenetrable soil, we now find out that it is. In addition, lets assume that right underneath that particular waste site is an aquifer serving a very large urban center.

Now, if that aquifer gets contaminated—if it is not already—and if individuals who have come in contact with that site or water begin to suffer some damages, obviously every lawyer in the neighborhood is going to start suing everybody they can find, including the United States.

I am concerned that, if we don't find some solution, since DOD is probably the largest single new provider in this country, we may end up paying a great deal more as taxpayers, unless we devise a system that properly compensates, and, if appropriate, places limits on the amount of recovery.

Mr. MCGRATH. Well, that is a concern that I share with you completely. And that is one of the reasons why I am the co-chairman of this working group. I will be happy to supply that information.

Mr. LEVITAS. I would appreciate that. Also you might, when you do that, if you say this is normally handled by the Lands Division, you might ascertain what sort of memoranda exists, if any, with respect to the Government's liability in matters of the sort I just identified.

Mr. MCGRATH. Suits against the Government for toxic waste sites?

Mr. **Levitas**. That is right. I have no further questions at this time.

Mrs. Johnson?

Mrs. **Johnson**. Thank you very much, Mr. Chairman.

I have a couple of other additional questions that occurred to me. First of all, you have referred in your testimony, to the Black Lung Program as an example of what we ought not to do. And I think in view of our conversation about compensation versus entitlement, could you spell out a little more clearly so we have it on the record, and more extensively than you did in your written testimony what it is in the Black Lung Program that you think we should avoid?

Mr. **McGrath**. Two things. One is, at least as I understand it, that the estimates that people made as to the cost of that program at the outset turned out, for whatever reason, to be grossly inadequate. The program simply cost a lot more than it was estimated. My caution there is that whatever program is put together let's make sure we know what the costs are.

I don't mean just the direct costs out of the Treasury; all the costs. Second, over time, by changing the presumptions, the inclusion of people in the program was vastly increased to a level where it has involved several billion dollars a year of costs.

Now, as I said earlier on, I am not involved day to day on the Black Lung Program. But I simply use it as an example of a program that, once set up, was expanded a good deal simply by fiddling a little bit with the presumptions. And what I am saying is that any solution that we come up with, we should look at it to see what little changes in presumptions will create what additional costs, what additional coverage and so on.

Mrs. **Johnson**. I agree with you that certainly a rational process of legislating would require that we have as good an estimate as possible of costs and that we understand what changes could be made in the program and what the effects would be, both fiscally and in human terms. But the implications of what you say tend to be that if it is going to cost a lot, we ought not to do it. And that expansion of a program is necessarily unwarranted.

I think we can expect that, whatever program we start with now, if we do it properly—and in my estimation that would be pretty narrowly drawn because that is where the information is now—that we would expect that the program will be expanded as we know more in a greater variety of areas.

Consequently, that while it is useful and important to be aware that cost estimates that we make now are only relative to the narrow definition of the program that we are drawing now, it is unrealistic to think that either we shouldn't act because we don't know what the future holds, or that we can act, and not expose ourselves to the need in the future to expand the program to achieve equity.

Mr. **McGrath**. Well, my concern is really this. Certain of the kinds of programs that have been proposed would create more risks of the type of problem found in the Black Lung Program than other ones, because, for instance, once you start saying here is a whole group of people we are going to compensate, it is very easy to, that, as time goes on, throw people who look pretty similarly situated, into the hopper. History shows that this frequently happens.

Now that means we could well start out with a program that might cost a billion or two billion a year early on, and be tens and tens of billions as the natural momentum got going. And our thought is that we really ought to think long and hard about whether we ought to do that, because what we would be creating would be something that 5 or 10 or 15 years from now might be an enormous program. And that, of course, among other things, would restrict other things we might want to do with the public treasury at that point.

And that is something we just, I believe, should not ignore. And I know that the committee isn't ignoring it. I am not suggesting that because I know what you are looking at. But it is a concern that I underline for that reason.

Mrs. JOHNSON. I appreciate your concern. It simply doesn't relieve us from acting. And so we are still stuck with the problem of definition.

Mr. McGRATH. That is right.

Mrs. JOHNSON. And eligibility at this point. I have only one other brief question.

Mr. LEVITAS. You may proceed.

Mrs. JOHNSON. More as a matter of calling it to your attention. Your working group will be making recommendations. Considering the diversity of your working group, aren't you concerned that the recommendations by the time they achieve consensus would be so general as to be not terribly useful? And if there is a difference of opinion, will agencies like EPA carry more weight than some of the other agencies in making those final determinations?

Mr. McGRATH. Well, I can only make a prediction based on the way we are organizationally set up now. Certainly, overall, the people who are involved in either are or have direct access to the highest level decisionmakers. I don't think if there is a right way to do something and those people are convinced that is the way it has to be done, those people——

Mrs. JOHNSON. It isn't an answerable question, but I think it is something we ought to be aware of because I think it may not be so easy for just the reasons we were talking about earlier.

Mr. LEVITAS. I think my colleague is making a gentle suggestion.

Mr. McGRATH. Yes; I did get the drift of the suggestion.

Mr. LEVITAS. Let me thank you, Mr. McGrath, for your attendance today and your contribution. I rather suspect we will be talking about this with each other in the weeks and months ahead as all of us address this terribly important problem that affects millions of people today, and millions in the future.

Tomorrow morning, the subcommittee will convene at 10 a.m. in room 2253 of the Rayburn Building, at which time we will hear from officials from the Centers for Disease Control, the National Institute for Occupational Safety and Health, and from others in the research community as well as the chemical industry. I expect that the hearings tomorrow will provide us with additional information on this important subject.

Accordingly, the subcommittee will stand in recess until 10 a.m. tomorrow morning.

[Whereupon, at 2:40 p.m., the subcommittee was recessed, to reconvene at 10 a.m., Wednesday, Nov. 9, 1983.]

HAZARDOUS WASTE CONTAMINATION OF WATER RESOURCES

(Compensation of Victims Exposed to Hazardous Wastes)

WEDNESDAY, NOVEMBER 9, 1983

House of Representatives,
Subcommittee on Investigations and Oversight,
Committee on Public Works and Transportation,
Washington, DC.

The subcommittee met, pursuant to call, at 10 a.m., in room 2253, Rayburn House Office Building, Hon. Elliott H. Levitas (chairman of the subcommittee) presiding.

Mr. Levitas. The subcommittee will please come to order.

This morning the Subcommittee on Investigations and Oversight of the House Committee on Public Works and Transportation is continuing its investigation now into its second year on the entire subject of contamination of the Nation's water resources and the impact it has on public health and on the economy of this country.

The hearings that we are in the midst of are focusing on one important aspect of that question, which is the matter of compensation for victims who have been exposed to toxic chemicals at abandoned hazardous waste sites. This will be the 5th day of hearings on this particular aspect of the subject, and while there is still some question in the minds of some of the witnesses we have heard from concerning the linkage between hazardous waste sites and health, there are others who feel either directly, or by coincidence, that they have been physically affected by this problem.

The present Federal laws on the subject omit compensation mechanisms for victims. We are in a situation where our laws seemingly provide for compensation for damaged property but not to individuals. We pay compensation, if you will, for the trees, but not for the people inside the houses. And what we are focusing on today and in the other hearings that we have held are both the scientific, as well as the procedural basis for dealing with the question of compensation for victims.

Do we have enough scientific evidence to legislate? Are there other questions which must be answered? What are the best approaches to take? Are the solutions Federal or State? Should we simply leave the law as it is? Should we make modifications in the tort law by way of presumptions, or should we create a new form of administrative compensation, similar to workers' compensation, for people exposed to hazardous waste? These are some of the extremely complex and difficult questions to which we are seeking answers. Today, we are going to hear from two important panels that I am satisfied will contribute greatly to our understanding of this subject and will enable us better to make those legislative decisions that will be made in the relatively near future as we approach the subjects.

The first panel will consist of Dr. Vernon Houk, who is Director of the Center for Environmental Health, Centers for Disease Control, in Atlanta. I understand that Dr. Donald Millar will not be here today due to illness in his family. I regret to have that sad news, but I certainly understand.

However, I understand that Dr. Fingerhut will be here. She is also with the National Institute for Occupational Safety and Health, and Dr. Sheila Jasanoff, who is with the Program on Science, Technology and Society, Cornell University, and a consultant for the National Science Foundation.

If the members of this panel will please come to the witness table. For those of you who are not familiar with the environment of this particular place, that clock behind you and the lights on it from time to time make noise, and different lights will go on, indicating occurrences on the floor of the House of Representatives. Two lights, which are now on display, indicate that a vote is in process. So I think what I will do, as we are also waiting for Congresswoman Johnson to join us, is go over at this time, vote, come right back and get directly into your testimony. Then we will make an announcement later in the morning as to whether we will go straight through or take a break around noon and then come back about 1:30. We will have to see what the circumstances are on the floor.

Accordingly, the subcommittee will stand in recess for 10 minutes.

[Recess.]

Mr. LEVITAS. The subcommittee will please come to order.

I have already introduced the first panel we will hear from today. Does any member of the subcommittee have an opening statement to make? If so, please feel free to do so.

Mrs. JOHNSON. Thank you, Mr. Chairman. Very briefly at this time, I do want to acknowledge and credit the participation of Arco and Union Carbide representatives here today. I understand and can appreciate to a certain extent that many of the so-called generator industries are reluctant to publicly address the victim compensation issue. Even though their appearances may not guarantee that the subcommittee gets answers to all of its questions, I want the witnesses to know that we do appreciate their contributions.

And I just want to make as a side comment the fact that the Union Carbide plant in my district has the statewide record for the longest number of days, consecutive days, when there has been no lost time due to an accident. So your record in terms of safety and employee concerns is really a very fine one in my State, and I hope nationally as well.

The other point I would like to make is that the 3-M Co. has also expressed an interest in helping the subcommittee examine this issue. Although 3-M representatives couldn't be here today I hope we will provide them with the opportunity to submit their views for the record.

Mr. LEVITAS. Thank you, Mrs. Johnson.

Does any other member desire to be heard at this time? If not, Dr. Houk, why don't we begin with you? If you would for the record identify yourself, your title and give us a brief description of what it is you do; then you may proceed.

TESTIMONY OF VERNON N. HOUK, M.D., DIRECTOR, CENTER FOR ENVIRONMENTAL HEALTH, CENTERS FOR DISEASE CONTROL, ATLANTA, GA; MARILYN A. FINGERHUT, PH.D., EPIDEMIOLOGIST, NATIONAL INSTITUTE FOR OCCUPATIONAL SAFETY AND HEALTH, CINCINNATI, OH; SHEILA S. JASANOFF, PROGRAM ON SCIENCE, TECHNOLOGY AND SOCIETY, CORNELL UNIVERSITY, CONSULTANT, NATIONAL SCIENCE FOUNDATION, ITHACA, NY

Dr. HOUK. Thank you, Mr. Chairman. I am Dr. Vernon N. Houk, Director, Center for Environmental Health, Centers for Disease Control and Assistant Administrator of the Agency for Toxic Substances and Disease Registries of the Public Health Service [PHS], Department of Health and Human Services. I am pleased to be here this morning to discuss with you some of the issues that relate to our activities under Superfund.

You asked for testimony on the issue of compensation for persons exposed to toxic chemical waste. Because I have no official responsibilities related to compensation policy, my testimony will be limited to those questions contained in your letter which address my duties in managing specific studies of the human health effects of exposure to hazardous substances. I direct a major effort within the Public Health Service to study the human health effects of community exposures to hazardous substances. From these studies, scientists on my staff and I frequently formulate recommendations to limit or prevent future and further exposure. I do not, however, recommend or set policy related to the compensation of persons inadvertently exposed and/or injured.

As you know, a Cabinet-level work group has been formed to address issues related to toxic compensation. The work of this group may be useful to you and your colleagues in this matter, and I understand you had testimony relating to this from Justice yesterday.

I would like to illustrate our Superfund activities under section 104i(1) related to the establishment and maintenance of registries, and section 104i(5) related to determining the relationships between exposure to toxic substances and illness. These two sections of the Superfund law present us with some of the most complex and perplexing scientific problems faced by public health officials today.

At Times Beach, MO and other dioxin sites, we have been attempting to measure the human health effects, if any, of exposure to 2,3,7,8 tetrachlorodibenzo-p-dioxin, the most toxic form of dioxin. Although the dioxin contamination incident in Missouri is not necessarily typical of the overall problem addressed by Superfund, it is useful for me to illustrate our work by describing both the immediate and the long-term program we have implemented in cooperation with the State of Missouri in response to the dioxin contamination.

In the early 1970's waste oil which had been mixed with dioxin-contaminated byproducts from the manufacture of various chemicals was spread widely in the town of Times Beach and in many other areas of Missouri to control dust. Just before Christmas last year, the Environmental Protection Agency informed us of the positive results of their dioxin testing program in Times Beach. EPA asked us to adivse them, the Federal Emergency Management Agency, and State officials regarding the potential human health effects which could result from contact with dioxin-contaminated soil.

Unfortunately, there are no easy answers to this question. At the time, and even today, very little is known about the human health effects of exposure to very low levels of dioxin. Almost all of what is known has been learned from animal studies, that is by exposing various species of animals to various levels of dioxin and observing the outcomes, then extrapolating from that information to arrive at assumptions about kinds of health effects which might be expected in humans. There have also been studies of workers who were inadvertently exposed to higher levels of dioxin while on the job, but the method of exposure in an occupational setting is quite different from the situation in Times Beach.

Although no adequate human health studies have been done, we knew based on the studies described above that dioxin could be potentially very highly toxic.

Between the time the soil samples had been collected by EPA and the analysis had been carried out, the town of Times Beach was flooded. When we received the results of the testing program the citizens of Times Beach had temporarily moved away from their flooded homes. Because of our deep concern about the potential for harmful health effects from dioxin, and the many uncertainties about this particular exposure incident and our fear that the flooding may have moved contaminated soil into the houses, we recommended that the citizens of Times Beach not return to their homes. Using our best estimate of exposure and health effects, we assessed the risk of dioxin exposure under the conditions present at Times Beach to be excessive if continued exposure were permitted to levels of dioxin above 1 part per billion.

We recognized then, and we recognize now, that this estimate of risk was based on a number of assumptions that required testing. We convened a panel of scientists from within and outside Government, from academia, industry, and environmental groups to review the process, assumptions, and calculations we used to arrive at the 1 ppb value. This group gave us valuable suggestions for improving the process, but did not take issue with our conclusion that long-term exposure to dioxin in soil at levels above 1 ppb in a residential setting should be avoided.

The State of Missouri, the St. Louis University School of Medicine, and St. Joseph Hospital participated in a pilot study. The pilot study consisted of a questionnaire survey of current and past health status, a physical examination for clinical signs and symptoms of potential health effects from dioxin, and a battery of specialized laboratory tests. On October 16, 1983, we reported the findings of our human health effects study. I would like to submit the Executive Summary of our report to you for the record.

[The following was received from Dr. Houk:]

MISSOURI DIOXIN HEALTH STUDIES PROGRESS REPORT, OCTOBER 16, 1983

EXECUTIVE SUMMARY

This interim progress report consists of 2 parts: (a) An overview of the public health response activities to the 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) environmental contaminations in Missouri, prepared by the Center for Environmental Health, Centers for Disease Control (CEH/CDC) and the Missouri Division of Health (MDH); and (b) a report on the pilot epidemiologic study of health effects due to TCDD contaminations in Missouri. The report of the pilot study was prepared by the above two agencies and the participating co-workers from the Departments of Medicine at St. Louis University School of Medicine, St. Louis, and St. Joseph Hospital, Kirkwood, Missouri.

In 1971, waste oil containing TCDD was sprayed for dust control on residential, recreational, and work areas in Missouri. For many of these areas, the presence, magnitude, and extent of environmental contamination was not documented until late 1982 and new information is being developed daily. The first document in this progress includes an overview of the environmental TCDD contamination in Missouri, a summary of the risk assessment process used to recommend what concentration of TCDD in soil in residential areas should raise a level of concern for human health, and an outline of the initial activities undertaken by MDH and CEH/CDC. The public health Agency (EPA) and the Missouri Department of Natural Resources (MDNR) on review and evaluation of environmental data, the development of health advisories to be used by EPA in considering remedial or preventive actions at specific contaminated sites, a helath education effort for the medical community and general public, a dermatologic screening clinic, establishment of a central roster of potentially exposed individuals, administration of a questionnaire survey, and a pilot medical-epidemiologic study of a group of individuals 1983.

The purpose of the pilot medical-epidemiologic (i.g., symptoms on medical history questionnaire, findings on physical examination, and results of laboratory tests) present a group of individuals with high risk of environmental TCDD exposure. The prelinary information on possible health effects from these exposures provided by the pilot study would enable medical epidemiologists to develop more refined and specific epidemiologic protocols to be used in further evaluations. Pilot studies by their nature are an initial probe to obtain an early impression of the types of problems being seen and thereby bring a problem into better focus and help future activities. Pilot studies are not by their nature meant to resolve all, or even the majority of, questions pertaining to a specific problem.

In this instance, the pilot medical-epidemiologic study was undertaken because many uncertainties were initially apparent in the Missouri dioxin situation. These uncertainties mitigated against a quick, simple design of a definitive health study. These uncertainties included: (a) very limited data on the types of health effects to be expected, with many potential effects to be evaluated, but very few known effects which are unique to dioxin exposure; (b) the limited, but rapidly emerging, environmental data at the time of status for large study groups was precluded; (c) the unavailability of a direct measure of exposure (such as a TCDD blood levels) for comparison with health findings in a study; and (d) the distribution of most highly exposed individuals among a number of different sites and settings.

Within the constraints and limits noted above, and with a resulting sense of caution, the following summary of the pilot survey is provided. With regard to the previously reported effects must closely associated with dioxin exposure, no cases of chloracne or porphyria cutanea tarda (or precursor stages of the latter) were documented. With regard to the large number of clinical tests for the organ systems suggested to be most sensitive to TCDD exposure (e.g., the liver), as well as the large number of tests of other systems and functions in the study, the results are largely negative, i.e., the majority of test results did not show an association with TCDD exposure status. The overall impression of negative results is based on three lines of reasoning: (a) There were very few statistically significant differences in these clinical tests between the high and low risk groups, (b) the group as a whole showed few clinical abnormalities and there was not a pattern of findings suggesting consistent trends of increased abnormalities in the high risk group, and (c) for specific areas (e.g., tests of liver function) multiple tests were consistent in not demonstrating abnormalities.

While these overall, first observations are encouraging and are not indicative of significant, dioxin-related effects in this pilot study population, several points should be kept in mind: (a) Inconclusive results should be evaluated in further studies; (b) Subtle health effects could possibly have been missed; (c) certain areas, such as psychological or behavioral function, were not evaluated in this pilot study; and (d) some degree of exposure misclassification of individuals could have occurred.

Consistent with our original purpose, however, MDH and CEH/CDC are developing protocols for further evaluation of groups thought to be exposed to TCDD in an attempt to provide more definitive conclusions. Efforts are also underway to develop the laboratory techniques to provide a direct measure of TCDD exposure (e.g., serum TCDD analyses) which would be helpful in providing accurate classification of exposure status.

It would be unwise to extrapolate from these preliminary findings to other possibly TCDD exposed groups in or outside of Missouri. Such extrapolation may be possible after more definitive studies of both health effects and dioxin exposure status are available.

Finally, public health policy in situations such as this environmental contamination with TCDD must continue to be focused on the prevention of any potential health effects even if such effects were not demonstrated in a small pilot study. Health effects could occur with a latency period exceeding the time from initial exposure to examination in this study. For this reason, all appropriate efforts need to be made to prevent human exposure.

Dr. HOUK. In summary, we could not definitively identify any significant health problems associated with exposure to the levels of dioxin present for this study group. While these overall first observations are encouraging and do not indicate significant immediate dioxin-related effects in this pilot study population, several points must be kept in mind: Inconclusive results on a number of tests will be evaluated in further studies, subtle health effects could possibly have been missed in this pilot phase, certain areas such as psychological or behavioral function were not evaluated in this pilot study, and some degree of exposure misclassification of individuals in the study may have occurred.

It would be unwise to extrapolate from these preliminary findings of our pilot study in Missouri to other dioxin-exposure incidents; either in the occupational setting, in other community settings, or among veterans of the Vietnam war. We intend to follow up with additional studies to delineate better the health effects in persons accidentally exposed to this potentially toxic compound.

Thus far, I have concentrated on our efforts to evaluate the immediate acute or subclinical effects of dioxin in people. You also asked about the efforts to identify the chronic, long-term effects which may result from exposure to low levels of toxic substances in the environment. We are attempting to answer the question: What long-term effects, if any, are there to persons exposed to dioxin and other hazardous substances? One of the most commonly recommended tools for studying the chronic or long-term effects of exposure is to construct a registry of persons exposed. The persons in the registry can then be tested periodically to determine their health status and eventually to determine the cause of death.

The use of registries to evaluate the long-term human health effects of toxic chemical exposures began prior to the passage of Superfund. In 1975, for example, we, in cooperation with the State of Michigan, set up a registry of 4,000 persons exposed to polybrominated biphenyls after the occurrence of an accidental mixture of that chemical into feed grains. As you will hear later, CDC's National Institute for Occupational Safety and Health has been studying the health effects of chemical exposures among workers through the establishment of registries.

Registries cannot be used to give quick conclusive answers to the many questions that people ask about the effects of toxic chemical exposure on their health or the health of their children. Even the most active and aggressively pursued studies using registries require decades to produce meaningful results. It is also true that even when the results of long-term studies are made available, the findings are likely to be hotly debated by scientists who honestly represent different points of view. I point out these inherent limitations in registries to call to your attention the fact that expectations for registries being used as tools to set public policy in the near future may be unrealistically high.

Even with these limitations, the Public Health Service has a commitment to the use of registries, where appropriate, to attempt to clarify the link between toxic exposures and adverse health outcomes. In 1980, the Public Health Service convened a group of experts to address this issue. The findings of this committee were presented to the Assistant Secretary for Health in June 1982 and with your permission, I would like to provide them for the record.

[The following was received from Dr. Houk:]

REPORT OF HHS/CCERP SUBCOMMITTEE ON USE OF LONG-TERM REGISTRIES FOR HEALTH FOLLOWUP OF POPULATIONS EXPOSED TO TOXIC HAZARDS

HEALTH FOLLOWUP REGISTRIES

I. Introduction

It is commonly suggested that health followup registries[1] be established as a means for assessing potential chronic or subacute health consequences of toxic chemical or radiation exposures in human populations. Although the concept of registry followup is intuitively simple, many practical difficulties exist. The issue is of growing importance, however, since opportunities for toxic exposure are increasing in industrial societies and since the low-dose nature of most such exposures focuses attention more on delayed than on acute health problems.

This report summarizes the principal considerations that underlie the establishment and operation of health followup registries. Its purpose is to assist policy development in the Public Health Service regarding promotion and support of such registries. Impetus for the report comes from a) recent toxic exposure episodes in which registry development has received close attention (Love Canal, Three Mile Island, Michigan polybrominated biphenyl (PBB) exposure), b) increasing concern for health followup registries of workers exposed to chemical toxins (for example, PCB, dioxin), and c) present emphasis on control of toxic wastes through the newly enacted "Superfund" legislation (Public Law 96-50: Comprehensive Environmental Response, Compensation, and Liability Act of 1980).

II. Establishment of registries

A health followup registry may be established for various scientific or medical reasons, ranging from assessment of health effects to early diagnosis and treatment of illness. It may also be established in a variety of exposure settings: known exposure to known hazard, potential exposure to known hazard, known exposure to potential hazard, or potential exposure to potential hazard. Different settings evoke different levels of scientific justification for registry followup or may result in different levels of followup intensity. Although, in practice, decisions regarding establishment of registries are often influenced by public concern, the decision process as far as possible should be dispassionate and objective. Considerations that deserve attention in this process can be described under three headings: scientific value and feasibility, resource availability, and ethical issues.

---

[1] The term "registry" can connote both disease registries in which groups of persons with a particular disease are available for studies of disease etiology and exposure registries in which persons with particular exposure histories are followed in hopes of defining health consequences. This report concerns exposure registries exclusively.

A. Scientific value and feasibility

Scientific considerations include 1) the relative importance of hypotheses that may be tested through any particular registry, 2) accessibility and size of the population to be registered and followed, 3) the adequacy of exposure information available for the population, and 4) the adequacy and availability of comparison information regarding unexposed populations.

1. Testable Hypotheses.—Before establishing a registry followup study, it is important to articulate as precisely as possible the scientific hypotheses that may eventually be tested by such a study. Possible settings range from ones where the nature of toxins and exposures is clearcut to ones where few data are available. Precise hypotheses will be more difficult to frame in the latter setting. It is also conceivable that, in situations where greater information is at hand, particular toxins may be of relatively little concern with respect to delayed health effects or may already be adequately understood. Although absolute answers cannot be expected in assessing the relative strength of proposed hypotheses, it is important that judgments be made as a first step before proceeding.

2. Population Size.—Aside from the intrinsic value of proposed hypotheses, various practical aspects of the population setting dictate whether or not testing such hypotheses is feasible. One is the size and accessibility of the population to be registered and followed. Most hypotheses regarding delayed toxic effects concern diseases of low frequency such as cancer which require a large population sample or a large accumulation of person-years for valid epidemiologic assessment. Small populations, particularly if dose levels are estimated to be low, will be less informative. This problem may be partly surmountable if registries of several small populations exposed to the same or similar toxins can be pooled for eventual analysis, although such pooling may be complicated by extraneous group differences. In any case, the need for large populations is itself a practical deterrent in view of resources needed to establish and maintain registries. Also of practical concern is the accessibility of populations for registration and followup. Registry development is easier in relatively immobile populations or where well-developed mechanisms already exist for tracing individuals. In the United States neither condition is common.

3. Exposure Information.—Of crucial importance is the state of exposure information available not just for the population as a whole but for each number of the population. The most attractive setting is one where a precise objective measure of each individual's exposure is available, either by direct biologic measurement or by some reliable reconstruction of individual dose, and—where information exists on other important variables related to health outcomes. Analysis can then relate individual health outcomes to individual exposures with some hope for objective dose-response assessment of the population. Situations where such precise individual information is available are rare. This is particularly true since toxic exposures may be transient, involving materials which are quickly cleared from the body and hence not available for dose assessment when plans for health studies are being marshalled some time after the exposure episode (persistent chemicals such as PCB and PBB are notable exceptions). Useful studies can be constructed, of course, using indirect exposure assessments either for individuals or for groups of individuals of individuals (work histories, records of residence near toxic waste dumps, etc.). However, the most interpretable situation is one in which direct information is retrievable.

4. Comparison Populations.—Perhaps the most critical scientific consideration is the availability of adequate population data against which to compare health outcome findings in exposed populations. In practice, this is often a relative matter whereby a relatively highly exposed population is compared to one with relatively light exposure (since for most toxic materials today it is not so much a matter of whether or not one is exposed as how much one is exposed). In the ideal followup registry such high-low comparisons can be made internally. This implies, of course, that precise individual exposure data, or sufficiently detailed group data, are at hand and that population size is adequate, the combination permitting calculation of dose-response relationships. Even under ideal circumstances, however, there may be need for comparison with outside populations, as is the case with more usual situations where exposure information is less precise and population size is limited. Whatever the setting, the important issue is comparability of populations. Information must be available to assess whether the exposed and unexposed populations being compared are in fact comparable in most respects other than the toxic exposure of interest. Such information may involve a fairly extensive array of variables ranging from standard demographic information to data concerning competing biologic influences, whether comparison populations are generated de novo in connection with a particular registry or are derived from existing national data sources (see below). In the absence of such mechanisms for making comparisons among populations, with adequate allowance for comparability considerations, registry followup studies are ill-advised.

B. Resource availability

The long-term, continuing nature of health followup registries dictates two special resource considerations: the need for sustained funding support to be committed for time periods measured in terms of decades and the need for sustained institutional commitments to maintain and utilize registries once started. Both of these considerations are self-evident, yet they may be the most difficult to fulfill given short-term shifts in government funding policies and the finite professional lifespan of individual investigators. Yet without consistent policy guaranteeing steady long-term support for followup registries, initiation of registry systems may be non-productive.

Institutional commitment at the federal level may call for the creation of some enduring focus for registry maintenance, complete with funding responsibilities. The existence of such a federal focus, perhaps within the PHS in cooperation with EPA, need not mean, of course, that all such registries would be centralized there, although bureaucratic pressure might inevitably develop in that direction. Instead, individual registry maintenance might better be a local concern through appropriate institutional commitments by state health departments and university centers, using the federal focus as a coordinating resource.

C. Ethical considerations

The third general area which needs consideration concerns the ethical impact of long-term followup registries on the individual persons being followed. No registry should be undertaken without informing each member of the population to be studied about the purposes of the registry and how it will or will not affect her or him (and if necessary her or his offspring), and without seeking each individual's consent for participation. Such informed consent is an essential part of any study; however, in the case of long-term population followup, it involves a greater ethical problem, not widely recognized, particularly for registries which will actively follow populations through repeated questionnaires or home visits. The problem centers on the sustained awareness by each individual being followed that he or she was exposed to a particular toxin and that it may yet affect his or her health. The difficulty that therefore must be resolved during the initial process of deciding to establish registry followup is whether such awareness is justified by the potential benefit for society as a whole from eventual registry findings. Potentially, this central ethical concern may favor the preferential development of registries using passive or non-obtrusive followup techniques (including record linkage) as opposed to registries relying on active population contacts. Such a potential trade-off would be of particular scientific concern in registry followup settings where interest centers on morbidity health parameters not easily assessed from existing record linkage systems.

III. Operation of registries

Once it is decided to establish a long-term health followup registry in a particular toxic exposure situation, attention shifts to how the registry will operate. As suggested already, many options exist, depending on the purposes the registry will serve and the resources available. Four areas of operation deserve comment: (1) the nature of baseline data to be collected at the start, (2) procedures to be used in population followup once baseline data are collected, (3) methods for analyzing eventual registry results, and (4) questions regarding where registry operations should be located and who should have access to registry data.

A. Baseline data

Three kinds of information are necessary as baseline data for long-term health followup of individuals. First are identification data, essential for tracing individuals over time and for linking registry information to independent data sets which can define different aspects of health outcome (for example, vital records, hospital records). In this category are name (including parents' names and women's maiden names), day, month, and year of birth, social security number, full address, phone number, addresses and phone numbers of close neighbors or relatives, name and address of employer, and available registration information for such things as insurance policies, union memberships, and veteran's benefits. All of these items can be invaluable for eventually tracing the whereabouts and vital status of persons participating in registry followup. The first 3 items (names, date of birth, social security number) are of special importance in that they represent the core requirement for potential followup through the National Death Index or other administrative record systems.

The second information category concerns documentation of individual exposure to the toxin or toxins of interest. Depending on the registry setting, such data may take many forms. Ideally it would center on some objective and precise biologic measurement of toxin levels in individuals. Lacking that (or in addition), indirect indicators of exposure should also be recorded: presumed mode of exposure (water, occupational contact, etc.), pertinent levels of toxin measured in the person's immediate environment, and duration of residence or work in relation to toxin exposure.

The third category of information comprises health covariates, facts about an individual's existing health, habits, and occupation that may influence eventual health outcomes (other than the particular toxic exposure of concern). Lists of information in this area can become formidable, and it is hard to define precisely what an option record should contain. Under existing health status one might confirm major health problems (for example, cancer, diabetes, genetic abnormalities), the relative importance of which would be strongly determined by the particular hypothesis being pursued by the registry followup study. Personal habits must include information about cigarette smoking and alcohol use but could also include information on many other items, particularly use of drugs or medications. Again, selection of items to record will depend on registry objectives. Occupational history is essential, although the detail of such history in terms of nature of employment, potential toxic exposures on the job, and changing occupations over time or throughout a lifetime can be most difficult to resolve.

The questionnaire administered to subjects enrolled in registry followup must be of manageable size, and hence not all items of potential interest can be included. In preparing questions to be asked of enrollees, particular attention must be given both to the precise format in which the questions are asked (so that comparison or linkage with similar data sets may later be possible) and to issues of information reliability: do the questionnaire responses provide hard objective data, and if not will they be verifiable from independent sources (hospital records, for instance)? If baseline data will require independent confirmation from other sources, operational plans for the registry must allow for such work to be done.

B. Followup procedures

Like the items of information recorded, procedures for subject followup should be fashioned to suit the nature and purpose of the particular registry. Where health endpoints of interest consist of disorders that are reasonably completely accounted for in mortality statistics (for example, many types of cancer), followup may be relatively passive. After initial registration, no further subject contact may be necessary, the registry relying on linkage of identifying data with death certificates via the National Death Index for deaths in 1979 and later and via Social Security records for earlier deaths, and subsequent tracing of available clinical records. Where morbidity information is desired, however, particularly if morbidity assessment of the registry population is needed at intervals throughout the total followup period, varying degrees of personal contact with registry subjects will be necessary. This can be done via phone, mailed questionnaire or interview visits to obtain desired information which subsequently may require confirmation through review of pertinent medical records or physician contacts. If biologic measurements of toxin levels in subjects are feasible and are needed to define changes in levels over time, collection of pertinent biologic specimens can be combined with the process of subject followup. Extent and frequency of followup, of course, is heavily dependent on available resources, since frequent personal contacts with subjects in any registry of reasonable size rapidly becomes a major ongoing activity for the staff involved. Coordination with providers of medical care to the population is necessary, since they often must receive information generated by the registry and serve as a source of data sought by the registry.

C. Analysis of data

Decisions to establish and maintain health followup registries entail commitment to perform full and timely analyses and interpretation of the data as they are assembled. Although this commitment may seem to go without saying, it deserves specific emphasis because of the extraordinarily long time periods involved in registry followup. It is easy if not likely for investigators or institutions initiating registry followup to lose interest or motivation to complete final analysis of data 20 or 30 years later. The need for analytic commitment must therefore be heavily stressed.

The process of data analysis and interpretation itself must also not be underestimated. The central need here is for adequate comparison populations. As indicated earlier, these can involve either populations internal to the registry, if the registry cohort itself is large enough and contains precise enough exposure data to permit dose-response exploration, or populations or population data drawn from the general community at large. The most likely scenario for analysis will actually involve combinations of the two, both internal and external comparisons, the latter often having the statistical advantage of large sample size.

General community data which may be feasible for use range upward in complexity from death certificates to various periodic population samples performed in this country both for developing health statistics and for other purposes. Prominent among these survey sources which might be useful in comparative analysis of registry data are the HANES and HIS programs operated by NCHS and the CPS (Current Population Survey) as well as the decennial census. Unfortunately the usefullness of such population samples is presently limited because they provide neither adequate record linkage information (e.g., social security number) nor certain items of information essential or important for health analysis studies. Particularly useful would be the eventual inclusion of a simple smoking history as part of the CPS or of the census itself. Efforts are underway, however, to meet this need at least partially through creation of data files for use in research regarding illness etiology (e.g., the Linked Administrative Statistical Sample project).

A final point with respect to data analysis is the importance of independent peer review both in the design phase of registry development and during the process of data analysis. The wide and multilateral public interests which focus on environmental exposures and on their potential long-term health implications dictate that broad scientific concensus underlie and sustain registry work once established. To establish and maintain an effective peer oversight system may be a sizable task but one which might appropriately be conducted through the central federal focus proposed earlier.

D. Registry location and access

It seems important, for optimal registry operation and data analysis, that the whole scope of work related to particular followup registries be focused in appropriate local health agencies or universities. The alternative that registry data collection be handled by one group, perhaps a local institution, and that data analysis later be handled elsewhere, perhaps at a central national focus, lacks the professional continuity and motivation necessary to fullfill registry objectives. The guiding principle, therefore, should be to encourage that registries be operated entirely in local settings where local community responsibility is felt and hopefully where local professional interest and competence can be brought to bear. There still remains, the need for a national focus for sustained registry support and policy guidance.

Data contained in registries should be available, as a basic rule, to any investigator who has appropriate scientific credentials and can demonstrate legitimate scientific need for use of the data. Guidelines whereby such access is guaranteed yet controlled will need to be developed. It is not desirable that particular individuals or institutions establishing registries consider that the data so generated remains their particular possession until their particular research purposes are fulfilled. The inherently public nature of data contained within registries of this sort must therefore be reaffirmed.

At the same time, the privacy of individual registry subjects must be scrupulously preserved. Such assurance must be stated in clear and unequivocal terms during the initial process of informed consent and must be safeguarded consistently thereafter. Again, the importance of this fundamental principle is underscored by the long-term nature of potential data usage in the context of long-term registry followup.

IV. Summary and recommendations

This brief review of long-term health followup registries stresses their complex nature scientifically, logistically, and ethically. At the same time, such registries are becoming of increasing importance for assessing chronic health consequences of environmental toxic exposures. As suggestions for PHS action in this area at the present time, this subcommittee would offer the following 2 particular recommendations:

(1) While particular registries are best managed on a continuing basis at local institutional levels, the long term commitments involved and the need for scientific consistency and comparability among registries call for development of a national focus, appropriately within PHS in cooperation with EPA, or promoting policy guidelines and peer review and for assuring sustained support for registry operations once initiated. The PHS should act to develop such a focus.

(2) Eventual analysis of registry followup data can be greatly enhanced if particular national data resources can be improved with respect to accessibility and utility

for health followup studies. The PHS should actively promote such improvements, both within its own agencies and within other parts of the federal establishment.

Dr. HOUK. This report on registries is not totally sufficient to establish a policy for nonoccupational registries within the PHS. There are too many unanswered questions:

For example, what measures of exposure should be used to set guidelines for eligibility for inclusion in a registry?

To what extent are people willing to participate over the course of a lifetime in active followup registries—a constant, stressful reminder of the fact that they were exposed to a toxic substance?

How can we assure that a commitment made today to establish and maintain a registry will be carried through over a period of 10, 20, 30 or 40 years? I might add, Mr. Chairman, that the resources for this are not inconsequential.

What level of followup is necessary, scientifically, to provide estimates of risk which can then be used to make sound decisions to manage the risk?

We are seeking to answer these questions. On December 21, 1983, the PHS is convening a meeting of scientists who have managed major long-term followup registries to seek their advice, based on their practical experience.

In carrying out our responsibilities under Superfund, we will cooperate with States, and with other Federal and local officials to establish and maintain registries of persons exposed to toxic substances as a result of an environmental exposure, whenever their inclusion in such registries would be scientifically appropriate or valuable for long-term followup or specific scientific studies. We are committed to defining the appropriate circumstances for such registries to be reviewed by scientists, and others, both within and outside Government by the end of May 1984.

In the meantime, both CDC and the agency for toxic substances and disease registry will continue to respond to specific incidents of human exposure to toxic or hazardous substances. We will also continue our efforts to measure both the immediate and long-term health effects, and to make sound recommendations to EPA for the attenuation of the risks.

Although the results of our studies may not provide the conclusive answers about health risks which are so necessary, we have hope that we can demonstrate strong associations, where they exist, between exposure and adverse health outcomes so that, very importantly, sir, reasonable people can make reasonable judgments.

This concludes my testimony.

Mr. LEVITAS. Thank you, Dr. Houk.

[The statement of Dr. Houk follows:]

STATEMENT OF VERNON N. HOUK, M.D., DIRECTOR, CENTER FOR ENVIRONMENTAL HEALTH, CENTERS FOR DISEASE CONTROL AND ASSISTANT ADMINISTRATOR, AGENCY FOR TOXIC SUBSTANCES AND DISEASE REGISTRY, PUBLIC HEALTH AND HUMAN SERVICES

I am Dr. Vernon N. Houk, Director, Center for Environmental Health, Centers for Disease Control (CDC) and Assistant Administrator of the Agency for Toxic Substances and Disease Registries (ATSDR) of the Public Health Service (PHS), Department of Health and Human Services. I am pleased to be here this morning to discuss with you some of our activities in implementing the Comprehensive Environmental Response, Compensation, and Liability Act of 1980, commonly known as Superfund.

In your letter of invitation requesting that I appear, you asked that my testimony concentrate on the issue of compensation for persons exposed to toxic chemical wastes. Because I have no offical responsibilities related to compensation policy, my testimony will be limited to those questions contained in your letter which address my duties in managing specific studies of the human health effects of exposure to hazardous substances. I direct a major effort within the Public Health Service to study the human effects of community exposures to hazardous substances. From these studies, scientists on my staff and I frequently formulate recommendations to limit or prevent further exposure. I do not, however, recommend or set policy related to the compensation of persons inadvertently exposed and/or injured.

As you know, a Cabinet-level work group has been formed to address issues related to toxic victims' compensation. The work of this group may be useful to you and your colleagues in this matter.

I would like to illustrate our Superfund activities under section 104i(1) related to the establishment that maintenance of registries, and section 104(5) related to determining the relationships beween exposure to toxic substances and illness. These two sections of the Superfund law present us with some of the most complex and perplexing scientific problems faced by public health officials today.

In your letter of invitation asking for me to serve as a witness before this committee, you asked that I describe to you our work at Times Beach, MO, where we have been attempting to measure the human health effects, if any, of exposure to 2,3,7,8 tetrachlorodibenzo-p-dioxin, the most toxic form of dioxin. Although the dioxin contamination incident in Missouri is not necessarily typical of the overall problem addressed by Superfund it is useful for me to illustrate our work by describing both the immediate and the long-term program we have implemented in cooperation with the State of Missouri in response to the dioxin contamination. In the early 1970's waste oil which had been mixed with dioxin contaminated byproducts from the manufactuer of various chemicals was spread widely in the town of Times Beach and in many other areas of Missouri to control dust. Just before Christmas last year, the Environmental Protection Agency informed us of the positive results of their doxin testing program in Times Beach. EPA asked CDC to advise them, the Federal Emergency Management Agency, and State officials regarding the potential human health effects which could result from contact with dioxin-contaminated soil.

Unfortunately, there are no easy answers to this question. At the time, and even today, very little is known about the human effects of exposure to very low levels of dioxin. Almost all of what is known has been learned from animal studies, that is by exposing various species of animals to various levels of dioxin and observing the outcome, then extrapolating from that information to arrive at assumptions about kind of health effects which might be expected in humans. There have also been studies of workers who where inadvertently exposed to higher levels of dioxin while in the job, but the method of exposure in an occupational setting is quite different from the situation in Times Beach.

From these studies we knew that dioxin could be potentially very highly toxic. Based on the non-human animal data, we assume it could contribute to the development of certain kinds of cancerous tumors and could adversely affect the unborn children of women who were exposed to the substance while pregnant. We also knew that dioxin accumulates in fat and in other human organs, particularly the liver, and is not easily excreted from the body. There is no known cure for dioxin poisoning. There was also great uncertainty about the extent to which dioxin in soil could be absorbed by humans who either worked in their yards, gardened, or otherwise were exposed to the contaminated dirt.

Between the time the soil samples had been collected by EPA and the analysis had been carried out, the town of Times Beach was flooded when heavy rains caused the Merrimac River to overflow it banks. When we received the results of the testing program the citizens of Times Beach had temporarily moved away from their flooded homes. Because of our deep concern about the potential for harmful health effects from dioxin, and the many uncertainties about this particular exposure incident and our fear that the flooding may have moved contaminated soil into the houses, we recommended that the citizens of Times Beach not return to their homes. Using our best estimate of exposure and health effects, we assessed the risk of dioxin exposure under the conditions present at Times Beach to be excessive if continued exposure were permitted to levels of dioxin above 1 part per billion (ppb).

We recognized then, and we recognize now, that this estimate of risk was based on a number of assumptions that required testing. The National Toxicology Program, within the Public Health Service, began conducting tests to determine whether, in the laboratory, animals exposed to the dioxin-contaminated soil from Times Beach would actually absorb dioxin into their systems. We also convened a panel of scientists from within and outside Government, from academia, industry and environmental groups to review the process, assumptions, and calculations we used to arrive at the 1 ppb value. This group gave us valuable suggestions for improving the process, but did not take issue with our conclusion that long-term exposure to dioxin in soil at levels above 1 ppb in Times Beach should be avoided.

The State of Missouri, the St. Louis University School of Medicine, and St. Joseph Hospital participated with scientists from the CDC in a pilot epidemiologic study of residents of several eastern Missouri dioxin Superfund sites, whom we judged to have experienced a spectrum of exposure to dioxin ranging from least heavily exposed to potentially most heavily exposed. The pilot study consisted of a questionnaire survey of current and past health status, a physical examination for clinical signs and symptoms of potential health effects from dioxin, and a battery of specialized laboratory tests. On October 16, 1983, we reported the findings of our Human Health Effects Study.

I would like to submit the Executive Summary of our report to you for the record. In summary, we could not definitively identify any significant health problems associated with exposure to the levels of dioxin present for this study group. While these overall first observations are encouraging and do not indicate significant immediate dioxin-related effects in this pilot study population, several points should be kept in mind: (1) inconclusive results on a number of tests will be evaluated in further studies; (2) subtle health effects could possibly have been missed; (3) certain areas, such as psychological or behavioral function were not evaluated in this pilot study; and (4) some degree of exposure misclassification of individuals in the study may have occurred.

It would be unwise to extrapolate from these preliminary findings of our pilot study in Missouri to other dioxin-exposure incidents; either in the occupational setting, in other community settings, or among veterans of the Vietnam War. We intend to follow up with additional studies to delineate better the health effects in persons accidentally exposed to this potentially toxic compound.

Thus far, I have concentrated on our efforts to evaluate the immediate acute or sub-clinical effects of dioxin in people. You also asked about our efforts to identify the chronic, long-term effects which may result from exposure to low levels of toxic substances in the environment. We are attempting to answer the question: What long-term health effects, if any, are there to persons exposed to dioxin and other hazardous substances? One of the most commonly recommended tools for studying the chronic or long-term effects of exposure is to construct a registry of persons exposed. The persons in the registry can be tested periodically to determine their health status and eventually to determine the cause of their death.

The use of registries to evaluate the long-term human health effects of toxic chemical exposures began prior to the passage of Superfund. In 1975, for example, CDC, in cooperation with the State of Michigan, set up a registry of 4000 persons exposed to polybrominated biphenyls after the occurrence of an accidental mixture of that chemical into feed grains. Also, CDC's National Institute for Occupational Safety and Health (NIOSH) has been studing the health effects of chemical exposures among workers through the establishment of registries. Among these is the worker registry of employees of industries which manufacture or manufactured products which may have been contaminated with dioxin. The intention is to assess the health status of workers who are listed in these registries and possibly to identify illness which may be related to a particular toxic exposure in the work place.

Registries cannot be used to give quick conclusive answers to the many questions that people ask about the effects of toxic chemical exposure on their health or the health of their children. Even the most active and aggressively pursued studies using registries require decades to produce meaningful results. It is also true that even when the results of long-term studies are made available, the findings are likely to be hotly debated by scientists who honestly represent different points of view. I point out these inherent limitations in registries to call to your attention the fact that expectations for registries being used as tools to set public policy in the near future may be unrealistically high.

Even with these limitations, the Public Health Service has a commitment to the use of registries, where appropriate, to attempt to clarify the link between toxic exposures and adverse health outcomes. In 1980, the Public Health Service convened a group of experts under the leadership of a CDC scientist to review the scientific and programmatic utility of registries and to make recommendations for a PHS policy. The findings of this committee were presented to the Assistant Secretary for Health in June of 1982 and with your permission, I would like to provide them for the record.

This report on registries is not totally sufficient to establish a policy for non-occupational registries within PHS. There are too many unanswered questions:

What measures of exposure should be used to set guidelines for eligibility for inclusion in a registry?

To what extent are people willing to participate over the course of a lifetime in active followup registries—a constant, stressful reminder of the fact that they were exposed to a toxic substance?

How can we assure that a commitment made today to establish and maintain a registry will be carried through over a period of 10, 20, 30, or 40 years?

What level of followup is necessary, scientifically, to provide estimates of risk which can then be used to make sound decisions to manage the risk?

We are seeking to answer these questions. On December 21, 1983, the PHS is convening a meeting of scientists who have managed major long-term followup registries to seek their advice, based on their practical experience.

In carrying out our responsibilities under Superfund, we will cooperate with States, and with other Federal and local officials to establish and maintain registries of persons exposed to toxic substances as a result of an environmental exposure, whenever their inclusion in such registries would be scientifically appropriate or valuable for long-term followup or specific scientific studies. We are committed to defining the appropriate circumstances for such registries to be reviewed by scientists, and others, both within and outside government by the end of May 1984.

In the meantime, both CDC and the Agency for Toxic Substances and Disease Registry will continue to respond to specific incidents of human exposure to toxic or hazardous substances. We will also continue our efforts to measure both the immediate and long-term health effects, and to make sound recommendations to EPA for the attenuation of the risks.

Although the results of our studies may not provide the conclusive answers about health risks which are so necessary, we have hope that we can demonstrate strong associations, where they exist, between exposure and adverse health outcomes so that reasonable people can take reasonable actions to protect public health and the environment.

This concludes my testimony. I would be pleased to answer your questions.

Mr. LEVITAS. Now, we will hear from Dr. Fingerhut.

Dr. HOUK. Mr. Chairman, with your permission Dr. Millar asked that we submit his statement for the record. I will summarize it. Then Dr. Fingerhut.

Mr. LEVITAS. Will Dr. Fingerhut be in a position to respond to questions?

Dr. HOUK. Yes, sir.

Mr. LEVITAS. First, the entire statements of all the witnesses will be made part of the record without objection.

Dr. Houk, if you would summarize for us Dr. Millar's statement.

Dr. HOUK. Thank you, Mr. Chairman. Dr. Millar is disappointed that he could not be here today. He particularly did want to come but, as you mentioned, he could not. He did ask me to summarize his statement.

I think this reflects the very close and necessary working relationship within the Centers for Disease Control between the occupational component and the nonoccupational component, and why we must work together and that we have worked together.

Dr. Millar is Director of the National Institute for Occupational Safety and Health of the Centers for Disease Control, Public Health Service, of the Department of Human Services. With me today is Dr. Marilyn Fingerhut, an epidemiologist in NIOSH's Division of Surveillance, Hazard Evaluations and Field Studies.

As you know, NIOSH was established by the Occupational Safety and Health Act of 1970, and is charged with studying the human health effects of occupational exposures to hazardous substances.

From the results of these studies and other available data, we make recommendations to prevent disease and injury among workers from such exposures. NIOSH, however, neither establishes nor recommends policy related to the compensation of persons exposed and injured.

It is in the performance of the Institute's research mission that several studies on dioxin are being conducted by NIOSH. I will first describe the "Dioxin Registry and Mortality Study" and then summarize other research exploring the relationship between soft-tissue sarcoma and exposure to dioxin.

The NIOSH dioxin registry has identified a cohort of workers who are known, by records of employment, to have worked in chemical processes which generated dioxin as a contaminant. Hence, these are workers who are known to have been potentially exposed to dioxin. Upon completion, the registry will contain a listing of the names, vital status, demographic information, and work histories for all U.S. workers potentially exposed to dioxin during the production of products such as trichlorophenol or pentachlorophenol. Enrollment of workers into the registry will be completed by the end of December 1983; 5,000 such workers at 10 U.S. facilities have already been identified. We are currently evaluating data systems at four additional sites, and, if the records are adequate, approximately 1,000 more workers will be added to the registry.

This group constitutes a unique population of persons with documentation of potential exposure to dioxin among whom meaningful epidemiological observations can be made. Many of the workers already identified have been exposed to dioxin-contaminated materials for 20 years or more. The registry will provide the data base necessary to conduct epidemiological research, the results of which will be a valuable source of information regarding potential human health effects from exposure to dioxin. In addition, the International Agency for Research on Cancer of the World Health Organization, with funding provided by the National Institute of Environmental Health Sciences, National Institutes of Health, is developing an international dioxin registry for countries other than the United States.

The mortality study, which is already underway, tests the hypothesis that soft-tissue sarcoma and other cancers may be associated with exposure to dioxin. Additionally, because information that can be obtained from a mortality study is limited to those causes of death which are coded on death certificates, we will seek more detailed health information through a questionnaire survey and a medical examination of several hundred living members of the cohort of exposed workers. In the first or pilot stage of this effort, a questionnaire and medical study will be administered to about 500 exposed workers and a comparable number of persons who have not been exposed. This study is designed to evaluate the presence of effects on the skin, liver, neurological, and immunological systems that have occurred among workers after exposure.

We also have extensively reviewed medical literature concerning the link between exposure to dioxin and soft-tissue sarcoma. In 1977, several clinical cases of soft-tissue sarcoma were observed among Swedish lumberjacks who had previously been exposed to dioxin-contaminated products. This observation led researchers in

Sweden to conduct two separate epidemiologic studies of the relationship of dioxin to soft-tissue sarcoma. Both studies found that workers with exposure to dioxin had a fivefold to sixfold greater risk of developing a soft-tissue sarcoma than those not exposed to dioxin.

Subsequently, three studies were conducted in the United States of workers exposed to the herbicide or its chemical precursor, trichlorophenol, products whose manufacture produces dioxin as a contaminant. No excess in total mortality or in deaths from malignant neoplasms was found in these studies. However, the number of workers in each study was small and the expectation of rare causes of death in such small groups was very low. Consequently, the failure to find excesses was of little significance. In order to have a meaningful sample to evaluate, we combined the data from the three studies and added results from a fourth unpublished study.

In the merged cohorts there were three deaths—2.9 percent of the total 105 deaths—reported by the researchers to be due to soft-tissue sarcoma; only 0.07 percent of total deaths, or less than 1 death, due to soft-tissue sarcoma was expected. A fourth individual in one of the cohorts died recently; the death also was reported as due to soft-tissue sarcoma. Three additional persons who worked at 2,4,5-T production facilities were reported by their physicians to have had soft-tissue sarcomas. Thus a total of seven cases were initially reported as due to soft-tissue sarcoma among workers exposed to dioxin.

In July, before the House Committee on Science and Technology, we discussed this issue. At that time, we knew of seven cases reported as soft-tissue sarcoma in U.S. workers. We indicated then that we were actively pursuing clarification of these reported cases.

In continuing these investigations, we have sought to confirm both the diagnosis and the history of exposure in each of these seven cases. We have obtained detailed work histories for each person and sent available pathological tissue specimens from each case for review by the Armed Forces Institute of Pathology and by an independent expert on the pathology of soft-tissue sarcomas.

Based on the expert review of specimens, we have recently stated that of the four cases reported to be soft-tissue sarcoma by the authors of the four U.S. studies, two of these cases are confirmed by expert pathologists as such. Both had documented exposure to dioxin-contaminated products. Of the three cases reported by physicians all were found to have soft-tissue sarcoma based on the review of their specimens by the experts; however, exposure of these employees to 2,3,7,8-tetrachlorodibenzodioxin-contaminated products could not be verified in a review of their work histories. We cannot determine whether these three workers had exposure to this contaminant.

As a result of a rigorous scientific process, we have now determined the following:

Four individuals had work histories documenting their employment in the manufacturing process of dioxin-contaminated products. Two of these have histologically verified soft-tissue sarcoma and two do not.

The three additional individuals who have histologically verified soft-tissue sarcoma have work records that do not provide documentation of their employment in the manufacturing process of the contaminant in question.

In sum, of the seven cases which were initially reported only two have histologically verified soft-tissue sarcoma for which we have documentation of their employment and the manufacturing process of the contaminant in question.

The two verified cases, while a small number, still represent an excess over the less than one that would be expected statistically. While our observations to date do not confirm a causal link between dioxin and soft-tissue sarcoma, they give us reason for continuing our investigations.

Mr. Chairman, this concludes Dr. Millar's summary. We would be happy to answer any questions you and members of the subcommittee may have.

[The statement of Dr. Millar follows:]

Statement by J. Donald Millar, M.D., Assistant Surgeon General, Director, National Institute for Occupational Safety and Health, Centers for Disease Control, Public Health Service, Department of Health and Human Services

Mr. Chairman and Members of the Committee: I am Dr. J. Donald Millar, Director of the National Institute for Occupational Safety and Health (NIOSH) of the Centers for Disease Control, Public Health Service, of the Department of Health and Human Services. Thank you for inviting me to testify on studies conducted by NIOSH which relate to long term health consequences among workers exposed to dioxin-contaminated products. With me today from the Institute is Dr. Marilyn Figerhut, an epidemiologist in our Division of Surveillance, Hazard Evaluations and Field Studies.

As you know, NIOSH was established by the Occupational Safety and Health Act of 1970, and is charged with studying the human health effects of occupational exposures to hazardous substances. From the results of these studies and other available data, we make recommendations to prevent disease and injury among workers from such exposures. NIOSH, however, neither establishes nor recommends policy related to the compensation of persons exposed and injured. As you know, a Cabinet-level work group has been formed to address a broad range of issues related to the compensation of the victims for exposure to toxic substances and the results of work by that group, when they become available, should prove useful to you in your deliberations on this issue. Because I have no responsibilities related to compensation policy, my testimony will be limited to those questions contained in your letter which address my duties in managing specific studies of human health effects of exposure to hazardous substances.

It is in the performance of the Institute's research mission that several studies on dioxin are being conducted by NIOSH. I will first describe the Dioxin Registry and Mortality Study and then summarize other research exploring the relationship between soft tissue sarcoma and exposure to dioxin.

The NIOSH Dioxin Registry had identified cohort of workers who are known, by records of employment, to have worked in chemical processes which generated dioxin as a contaminant. Hence, these are workers who are known to have been potentially exposed to dioxin. Upon completion, the Registry will contain a listing of the names, vital status, demographic information, and work histories for all U.S. workers potentially exposed to dioxin during the production of products such as trichlorophenil, 2,4,5-trichlorophenoxyacetic acid (2,4,5-T), or pentachlorophenol. Enrollment of workers into the Registry will be completed by the end of December 1983; 5,000 such workers at ten U.S. facilities have already been identified. We are currently evaluating data systems at four additional sites, and, if the records are adequate, approximately 1,000 more workers will be added to the Registry.

This group constitutes a unique population of persons with documentation of potential exposure to dioxin among whom meaningful epidemiological observations can be made. Many of the workers already identified have been exposed to dioxin-contaminated materials for twenty years or more. The Registry will provide the data base necessary to conduct epidemiological research, the results of which will be a valuable sorce of information regarding potential human health effects from exposure to dioxin. In addition, the International Agency for Research on Cancer of the

World Health Organization, with funding provided by the National Institute of Environmental Health Sciences, National Institutes of Health, is developing as international dioxin registry for countries other than the United States.

The mortality study, which is already under way, tests the hypothesis that soft tissue sarcoma and other cancers may be associated with exposure to dioxin. Additionally, because information that can be obtained from a mortality study is limited to those causes of death which are coded on death certificates, we will seek more detailed health information through a questionnaire survey and a medical examination of several hundred living members of the cohort of exposed workers. In the first or pilot stage of this effort, a questionnaire and medical study will be administered to about 500 exposed workers and a comparable number of persons who have not been exposed. This study is designed to evaluate the presence of effects on the skin, liver, neurological and immunological systems that have occurred among workers after exposure.

We also have extensively reviewed medical literature concerning the link between exposure to dioxin and soft tissue sarcoma. In 1977, several clinical cases of soft tissue sarcoma were observed among Swedish lumberjacks who had previously been exposed to dioxin-contaminated products. This observation led researchers in Sweden to conduct two separate epidemiologic studies of the relationship of dioxin to soft tissue sarcoma. Both studies found that workers with exposure to dioxin had a five to six-fold greater risk of developing a soft tissue sarcoma than those not exposed to dioxin.

Subsequently, three studies were conducted in the U.S. of workers exposed to the herbicide 2,4,5-trichlorophenoxy acetic acid (2,4,5-T) or its chemical precursor, trichlorophenol, products whose manufacture produces dioxin as a contaminant. No excess in total mortality or in deaths from malignant neoplasms was found in these studies. However, the number of workers in each study was small and the expectation of rare causes of death in such small groups was very low. Consequently, the failure to find excesses was of little statistical significance. In order to have a meaningful sample to evaluate, we combined the data from the three studies and added results from a fourth unpublished study. In the merged cohorts there were three deaths (2.9% of the total 105 deaths in the merged cohorts) reported by the researchers to be due to soft tissue sarcoma; only 0.07% of total deaths, or less than one death, due to soft tissue sarcoma was expected. A fourth individual in one of the cohorts died recently; the death also was reported as due to soft tissue sarcoma. Three additional persons who worked at 2,4,5-T production facilities were reported by their physicians to have had soft tissue sarcomas. Thus a total of seven cases were initially reported as due to soft tissue sarcoma among workers exposed to dioxin. In July of this year, we reported these preliminary observations to the House Committee on Science and Technology.

In continuing these investigations, we have sought to confirm both the diagnosis and the history of exposure in each of these seven cases. We have obtained detailed work histories for each person and sent available pathological tissue specimens from each case for review by the Armed Forces Institute of Pathology and by an independent expert on the pathology of soft tissue sarcomas. Based on the expert review of specimens, we have recently stated that of the four cases reported to be soft tissue sarcoma by the authors of the four U.S. studies, two of these cases are confirmed by expert pathologists as such. Both had documented exposure to dioxin-contaminated products. Of the three cases reported by physicians all were found to have soft tissue sarcoma based on the review of their specimens by the experts; however, exposure of these employees to dioxin-contaminated products could not be verified in a review of their work histories. We cannot determine whether these three workers had exposure to dioxin.

In July, before the House Committee on Science and Technology, we discussed this issue. At that time, we knew of seven cases *reported* as soft tissue sarcoma in U.S. workers. We indicated then that we were actively pursuing clarification of these reported cases. As a result of a rigorous scientific process, we have now determined the following:

Four individuals had work histories documenting their employment in the manufacturing proces of dioxin-contaminated products. Two of these have histologically verified soft tissue sarcoma and two do not.

The three additional individuals sho have histologically verified soft tissue sarcoma have work records that do not provide documentation of their employment in the manufacturing process of the contaminant in question.

In sum, of the seven cases which were initially reported only two have histologically verified soft tissue sarcoma for which we have documentation of their employment and the manufacturing process of the contaminant in question.

The two verified cases, while a small number, still represent an excess over the less than one that would be expected statistically. While our observations to date do not confirm a causal link between dioxin and soft tissue sarcoma, they give us reason for continuing our investigations.

Mr. Chairman, this concludes my summary of the NIOSH dioxin studies. We would be happy to answer any questions you or other members of the subcommittee may have.

Mr. **Levitas.** Thank you, Doctor.

Why don't we hear from Dr. Jasanoff before we get into questions?

Ms. **Jasanoff.** Thank you, Mr. Chairman.

Mr. **Levitas.** Again, Dr. Jasanoff, we welcome you. If you would, give us your full name, employment, and general description of what you do.

Ms. **Jasanoff.** I am Sheila S. Jasanoff, a senior research associate at the Program on Science, Technology and Society at Cornell University. I am pleased to be here this morning to talk about my participation in the study carried out by the National Science Foundation's Division of Policy Research and Analysis about 2 years ago on the issue of victim compensation. I have here with me this morning a copy of the report that was prepared in consequence of that study if the subcommittee should wish to look at it.

The objective of the victim compensation study was to look at the question of policy responses in a more concrete context than it had previously been examined in. So instead of having academic analyses of the alternative approaches, the National Science Foundation took a case study approach which would subject the same facts to different types of compensation models in an effort to yield some conclusions about the comparability of these models and the relative advantages and disadvantages they offer.

One principal thrust of the study at all times was to see how the linkage between uncertainties on the scientific side and procedural uncertainties created by the different compensation approaches fit together to affect the probability of compensation in different cases. And the case studies were chosen to represent a spectrum of substances about which different degrees of scientific information were available, ranging from a relatively well-known health hazard, scientifically well documented, namely, asbestos, though unfortunately that case study was never completed, and three others that went from relatively certain to quite uncertain in the range of scientific information then available.

The study that I personally did was on 2,4,5-T and one focus of interest was the fact that 2,4,5-T, although it fell into the quite uncertain health hazard category, was contaminated by dioxin which was known at that time to be a highly toxic compound. The study was coordinated from the start in ways that would ensure the comparability that we were seeking. The three case study performers met together to decide on which model compensation processes would be looked at, and also what kinds of criteria of evaluation could be applied to the case studies. The objective then was the development of factual situations which we constructed on the basis of information available about exposure conditions, and a fitting of the different fact situations to the approaches taken in the different compensation processes, and finally, an evaluation section in each case study that used the same criteria.

Briefly, the outcome of the study was to show that there were two main ways in which victims of toxic substance pollution can encounter difficulty in trying to obtain some remedy for their injuries. The obstacles fell either into a legal and procedural subgroup or into a science-related subgroup. Obviously there are overlaps between these. But just to exemplify what I mean, in the first subgroup there are things like statutes of limitations which did not take account of the fact that many injuries associated with toxic substances may not become apparent to the sufferer until a certain amount of time has elapsed between the exposure and the injury itself, and these statutes of limitations in some cases completely bar recovery and make it very difficult in others.

In the second category, namely, limitations imposed by science, were the standards of proof that victims of toxic substance pollution would have to meet under virtually all the compensation systems that we looked at. A total of six systems were examined in the course of the study. Only one required no showing of causation, and that was the Social Security disability insurance scheme. The others, even including workers' compensation, which was originally set up to be a relatively noncausal no-fault approach to compensation, did entail a certain showing of a causal relationship between exposure and injury.

In the course of my case study on 2,4,5-T, I concluded that with respect to the causal showing it would be very difficult for the kinds of victims and persons exposed to 2,4,5-T, with the injuries that might be caused by 2,4,5-T to meet the standard of proof, even in systems that were specifically constructed to ease the burden of proof for victims. Thus, one of the main approaches that we were considering at the time was the Brodhead bill. That bill required as a minimum threshold showing that victims would have to establish that their exposure resulted in the etiology of the disease or injury for which they were claiming compensation. Looking at the scientific evidence then available on 2,4,5-T and dioxin, it appeared almost certain that most of the kinds of victims we would expect to see would not be able to meet that showing.

The NSF report did not so much recommend a particular policy approach as summarize the kinds of pros and cons associated with the different policy approaches. My own reaction to the systems we studied was that whatever policy approach is undertaken in this area, if a comprehensive policy is developed for toxic substance victim compensation it will have to combine theoretical approaches that reflect a number of different philosophies of compensation.

Obviously one extreme is to ignore the causal question completely and to say that we want to compensate victims for the injuries they suffer. In this case it makes no sense to have a policy that relies primarily on a producing industry for the funds required for compensation. At the other extreme, one could keep the tort system with no changes. But I think the study amply demonstrated that that system is quite inefficient in a number of regards, and also inequitable in its selection of certain people to compensate and others not. Some sort of middle road is exemplified in the study we did by a proposed collective liability system which would have set up two different approaches to compensation. One would be for victims who could not uniquely identify a manufacturer or producer of the substance that possibly injured them. Those people would be entitled to recovery from a fund, a concept familiar from a number of Federal statutes. The other approach resembled tort law more in that it required victims to go against specified manufacturers and producers, and correspondingly, that approach entitled victims to a high level of compensation because it included punitive damages as well.

This concludes my prepared statement. I would be happy to answer questions.

[The statement of Ms. Jasanoff follows:]

Statement of Sheila Jasanoff, Program on Science, Technology and Society, Cornell University

Good morning, Mr. Chairman and members of the Subcommittee. I an Sheila Jasanoff, Senior Research Associate in the Program on Science, Technology and Society at Cornell University. I an pleased to be here this morning to report on a study of toxic substance victim compensation carried out by the National Science Foundation (NSF) in 1981. The purpose of the study, in which I participated as a consultant, was to evaluate the adequacy of several existing and proposed victim compensation mechanisms, taking into account the impact of incomplete scientific knowledge on the settlement of claims.

In my remarks I will briefly describe the objectives and methodology of the study and the results of my own case study analysis of the herbicide 2,4,5-T. I will also summarize the major conclusions and policy options that emerged from the study as a whole.

STUDY OBJECTIVES AND APPROACH

To provide a concrete factual context for the evaluation of compensation systems, NSF selected a case study approach centering on four substances, each of which presented different gaps in scientific information and different problems of proof for injured parties. The four substances were asbestos (a well-known and scientifically recognized health hazard), nitrilotriacetic acid (as substance of uncertain hazard to health), 2,4,5-T (an uncertain health hazard, but contaminated by a well-known toxic compound, TCDD or dioxion), and diethylstilbesterol (a substance recognized as safe in certain uses but presenting a health hazard to an identifiable subgroup of the population). Upon reviewing work plans submitted by outside consultants, NSF commissioned three case studies focusing on the substances whose effects on human health were most inconclusive and controversial: NTA, 2,4,5-T and DES. (A fourth study on asbestos was commissioned but never completed.)

The performance of the case studies was carefully coordinated from the outset to ensure that the findings would be genuinely comparable. The case study performers met once at the start of the project to select the compensation systems that would be analyzed and a to design a set of common criteria for evaluating them. Each performer agreed to examine the tort liability system and the Brodhead bill (H.R. 5074, 96th Congress, 1st Session), one of the leading legislative proposals for establishing an administrative compensation scheme at the time of the study. Further, each performer was required to evaluate at least one other compensation framework more closely tailored to the facts of the individual case studies. In all, six compensation systems were examined in the three cases studies: the tort system, the Brodhead bill, the LaFalce bill (H.R. 5291, 96th Congress, 1st Session), workers' compensation, social security disability insurance (SSDI), and a proposed collective liability system.

Each case study involved three discrete tasks. First, the scientific information available on each substance was reviewed and the uncertainties relevant to the disposition for compensation claims were identified. Second, each performer constructed a set of hypothetical fact situations to illustrate the kinds of exposure and injuries that might be associated with each substance. Third, the selected compensation mechanisms were applied to these fact situations and the effectiveness of each was measured in terms of the previously agreed upon criteria. Ten of the fifteen evaluation criteria related to the institutional and procedural structure of the compensation systems: choice of forum and factifinder, identification of plaintiffs and defendants, evidentiary showing, financing of awards. The remaining five addressed the equity and efficiency aspects of different compensation processes, including the time to recovery, the cost of pursuing claims to completion, the deterrent effect of awards, and the utility of the process for generating new information about toxic substance-related injuries.

Preliminary drafts of the case studies were circulated among the performers for comment and criticism. In this way a close coordination of the separate efforts was maintained throughout the project. The completed case studies were edited and published by NSF as a research report entitled "Compensation for Victims of Toxic Substance Pollution—Assessing the Scientific Knowledge Base" (March, 1983).

THE 2,4,5-T CASE STUDY

I would like now to turn to my own study of 2,4,5-T and the conclusions I drew from that analysis. At the time of the NSF project, 2,4,5-T, a component of Agent Orange, was already implicated in lawsuits growing out of the use of that defoliant during the Vietnam war. Much of the controversy focused on the effects of dioxin, a contaminant unavoidably produced in the manufacture of 2,4,5-T and present in commercial preparations of the herbicide in at least trace amounts. To assess the availability of compensation for health injuries caused by 2,4,5-T, I constructed a number of fact situations covering the range of possible exposures: those environmentally exposed to aerial application of the herbicide, and those occupationally exposed both during the manufacturing process and in the course of application. The class of potential victims also included children born with birth defects possibly as a result of parental exposure to the substance.

Both 2,4,5-T and dioxin are the subjects of a voluminous scientific literature comprising a wide variety of animal and human studies and examinations of the substances' mutagenic potential. However, a review of this literature (carried out with the assistance of a researcher familiar with 2,4,5-T) revealed surprisingly few areas of consensus. It is well known, for example, that exposure to dioxin and to 2,4,5-T can result in such toxic effects as chloracne and other dermatological injuries, metabolic disorders, neurological symptoms and psychological alterations. But it was unclear in many cases whether the reported effects were induced by 2,4,5-T itself, dioxin, a combination of the two, or some other contaminant. The genotoxic effects of both compounds were even more uncertain. While dioxin was identified as a teratogen at high doses as early as 1969, later studies using 2,4,5-T with known low concentrations of TCDD yielded conflicting results on the question of teratogenicity. Reports on the carcinogenicity of these compounds were inconclusive as well, although there was evidence that chronic administration of TCDD could produce excess neoplasms in test animals.

Given the pervasive gaps and conflicts in the scientific literature, I concluded that it would be extremely difficult for any of my hypothetical victims to recover for their injuries under the three cause-based compensation processes I evaluated (tort law, the Brodhead bill and workers' compensation). Social security disability insurance offered the most certain prospects for recovery, since awards in that framework do not depend on a showing of causation. However, since SSDI covers only persons who have been gainfully employed, this mechanism would offer nothing to unemployed victims, such as environmentally exposed children or children born with birth defects occasioned by pre-natal exposure to 2,4,5-T.

STUDY CONCLUSIONS

All three case studies illustrated certain systematic difficulties confronting persons attempting to obtain compensation for injuries caused by toxic substances. One set of problems relates to the proof of causation, which is the greatest obstacle to recovery for most victims. The inadequacy of current scientific knowledge contributes enormously to the claimant's evidentiary burden. The case studies revealed a persistent dearth of evidence about the low-dose effects of environmental pollutants. Both epidemiological and animal data present inconclusive evidence about the human health effects of toxic substances. In all cases, the difficulty of establishing a scientifically plausible causal showing is compounded by such factors as the cost of expert testimony and the time lag between exposure and the detection of adverse health effects.

A second set of problems relates to administrative and procedural rules that create characteristic barriers to recovery in each compensation system. Tort law, responding only slowly to the specific issue of toxic substances, still presents the greatest number of such impediments, for example, restrictive statutes of limitations, legal obstacles against suing multiple defendants, rigid evidentiary rules excluding speculative scientific information, and limitations on class actions. These features of the tort system have been widely criticized in a number of more recent studies as well, including, prominently, the report to Congress prepared by the Superfund § 301(e) Study Group (September, 1982).

Administrative compensation schemes, such as the Brodhead bill, can ease the path to compensation by specifically addressing both sets of problems encountered in existing recovery processes. Proposals directed explicitly at the issue of toxic substance injuries generally lower the claimant's burden of proof through use of carefully structured rebuttable presumptions. Such proposals can also eliminate artificial impediments, such as overly rigid statutes of limitations, reduce the cost of preparing and processing claims, and facilitate the production and consolidation of relevant scientific information. However, my analysis of the 2,4,5-T case suggested that even the reduced burden of proof associated with administrative compensation processes may be difficult to meet for many toxic substance victims. The case for recovery would remain highly problematic for those exposed to very low doses of environmental pollutants and those whose symptoms are not uniquely related to a particular toxic exposure. In an important sense, then, all cause-based compensation systems are likely to prove under-inclusive, i.e., they will only compensate a fraction of those actually hurt by exposure to toxic substances.

POLICY OPTIONS

The range of mechanisms examined in the NSF study represent two fundamentally divergent pholosphies of compensation. One, exemplified by the SSDI system, forcuses exclusively on the need to make the victim whole and to do so with reasonable efficiency. This approach is unconcerned about the source of the victim's injuries. Although claimants may have to meet minimal threshold requirements, as for receiving SSDI benefits, these have nothing to do with establishing causation. As a result, this approach offers toxic substance victims the surest route to recovery. By eliminating the need to prove causation, it also does away with the burden of grappling with the voluminous, complex and frequently inconclusive scientific record that currently forms the basis for most toxic substance-related claims.

A very different philosophy, one geared to making the "polluter pay," characterizes all cause-based compensation systems. The assumptions underlying this approach are both moral and economic. They include the judgment that the cost of chemically induced injuries should fall on those who caused them, and the belief that such costs can be borne most efficiently by manufacturers and producers, who may, in turn, pass them on to the larger consuming public.

Most of the compensation processes under serious consideration today fall into the second category. However, even under this heading one can discern a number of distinct policy alternatives. One course is simply to let the existing mechanisms evolve gradually to meet the demands created by pollution-related claims. Cases like *Sindell* v. *Abbott Laboratories, et al.*, in which the California Supreme Court adopted the theory of "market share liability," indicate a willingness on the part of the courts to evolve creative doctrines in the face of new legal challenges. Another is to intervene legislatively only to the extent of removing glaring inequities in existing processes, for example, certain precedural barriers to recovery in both the tort and worker compensation systems.

But these are patchwork solutions. They will not substantially reduce the delays, frustrations and anxieties experienced by most toxic substance victims. They will not significantly mitigate the costs of pursuing compensation claims. Nor will they limit the impact of chance factors which result in adequate compensation for a victim in one jurisdiction while denying all recovery to a similarly situated claimant in another. A continuation of the present arbitrary and uncertain state of affairs, moreover, hurts not only those who are injured, but also those potentially subject to liability. It discourages industry from systematically dealing with compensation issues, since the success rate for victims is, on average, quite low. At the same time, it leaves open the possibility of disastrously high damage awards in an unpredictable minority of cases.

A mechanism explicity designed to deal with the issue of victim compensation appears the only viable response to these problems. In my view, the most promising option considered in the NSF study is the hypothetical collective liability system. It rests on a philosophy reflected in a number of existing federal laws, including the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA) of 1980. It is also similar in conception to compensation schemes adopted in a number of other countries, for example, West Germany's framework for handling drug-related injuries.

The collective liability proposal presents two attractive features. First, it makes available a fairly low-cost way for victims to claim compensation even when they cannot uniquely identify the manufacturer or producer responsible for their injuries. Through creation of a fund, it forces manufacturers of toxic substances to set aside a regular fraction of profits for purposes of compensation. In these respects, the collective liability approach approximates some of the efficiencies associated with no-fault liability systems, without, however, completely dispensing with the need to prove causation. For victims capable of meeting a higher standard of proof, the proposal also offers a modified version of a fault-based recovery process. In particular, this avenue allows the recovery of punitive damages against identified defendants, thus deterring reckless conduct, but places ceilings on such awards to keep them within reasonable bounds. One may well disagree with the details of the collective liability proposal outlined in the NSF study. It appears to me, however, that a satisfactory solution to the victim compensation problem will have to blend elements of several different approaches, as this proposal seeks to do. This evaluation represents my personal opinion and not that of the National Science Foundation.

This concludes my prepared statement. I would be happy to respond to questions.

Mr. LEVITAS. Thank you very much, Dr. Jasanoff. Most interesting. At least we can take comfort in the fact that others have been plowing this ground before us. We are not the first explorers of these uncharted waters.

Let me start first by trying to clarify something in Dr. Millar's statement. Toward the end of the statement, on page 5, you talk about these cases that you have studied that were originally discussed back in July. Were there any additional cases looked at since July?

Dr. FINGERHUT. No.

Mr. LEVITAS. Of those seven cases that you went into greater detail, only two have histologically verified soft tissue sarcoma for which we have documentation of their employment and the manufacturing processes of the contaminant in question. Now, that does not say to me that those other five might not have also fallen in that same category; is that correct?

Dr. FINGERHUT. The definition that we have used for exposure is a restrictive one. We looked for a record that the person was assigned to making 2,4,5-T or to making trichlorophenol. In general for production workers, one can find their regular assignments. This person worked regularly in the 2,4,5-T department. One would not find temporary assignments. Six of these seven people were production workers. And so we have a record of their regular assignments throughout their career. The seventh person was a maintenance worker.

Many maintenance workers in chemical facilities never have a record of assignment to a particular department, because they work throughout the entire complex. Therefore, the maintenance worker may well have been in the 2,4,5-T area, but he would not have a record of documentation. So we have used a restrictive——

Mr. LEVITAS. So you have a very restrictive universe——

Dr. FINGERHUT. That is right.

Mr. LEVITAS [continuing]. You are really looking at, even though the others might well have had similar exposures. You just don't know.

Dr. FINGERHUT. That is right. There is no documentation of it. We don't know. That is right.

Mr. LEVITAS. Now, even with that restrictive definition, you then say the two verified, and you underline verified, I guess anticipating the question I just asked you, while a small number still represent an excess over the less than one which would be expected statistically. As I understand your testimony, it represents that even that restricted verified number represents almost three times what you would normally anticipate.

Dr. **Fingerhut**. Let me back up just to one point. The verified refers to pathologic confirmation by soft tissue sarcoma experts that they had their pathology of soft tissue sarcoma. We reviewed the work history records and used documentation as I explained earlier. The first four cases, one to four, were originally from small company studies in the United States. Those workers were reported by the companies in studies they had done of their own workers who made 2,4,5-T or trichlorophenol. Of those four we found, yes, they did work in those departments, by looking at their records. And the two independent reviewers of their pathology found that two had soft tissue sarcoma, two did not. So two of those four is still above what we would have——

Mr. **Levitas**. What is, statistically, the magnitude of the excess?

Dr. **Fingerhut**. The NIOSH researchers wrote a letter in 1981 to *Lancet*, a medical journal, reviewing the then existing literature. At that time three of these four individuals were deceased and had been reported as deceased. In the 4 studies put together, there were 105 deaths. The 3 deaths due to soft tissue sarcoma out of 105 was 2.9 percent.

The researchers used national statistics to get an estimate of what percent of deaths you would suspect in the male population, ages 20 to 85, and found that one would expect 0.07 percent of deaths to be due to soft tissue sarcoma.

Mr. **Levitas**. That would, therefore, be about three times what you would expect; that is, what you found is three times what you would expect. If you would expect 0.07 percent and you found 2.9 percent of the total of 105 deaths, that, if my arithmetic is correct, is about 3 times, 4 times.

Dr. **Fingerhut**. It is about 40 times.

Mr. **Levitas**. Forty times.

Dr. **Fingerhut**. Yes, sir.

Dr. **Houk**. Mr. Chairman, could I——

Mr. **Levitas**. I see. OK.

I had the zero in the wrong place.

Dr. **Houk**. Could I respond, Mr. Chairman.

When one is looking for rare events and statistically you suspect 0.1 death or one-half a death or one-third you obviously——

Mr. **Levitas**. What is one-half a death?

Dr. **Houk**. You obviously can't find one-half a death, you can't find one-third of a death, so if you find no deaths, it doesn't make it a negative study, and if you find one, it doesn't make it a positive study. But if you find two, you become a little more concerned. If you find three, heightened concern; if you find four, more heightened concern.

These epidemiologic data do not prove, do not ever demonstrate conclusively cause and effect. We live in a society fortunately that we cannot do those studies. We can't purposely expose people to toxic chemicals to get cause and effect.

I come back to my statement, sir, that what we are trying to do is demonstrate association if it is there; to remove as many confounders as possible, other things that could influence this—so that reasonable policymakers can make reasonable decisions.

Mr. **Levitas**. Right. I accept that. I don't think we expect that the epidemiological data will be able to conclusively establish cause and effect.

But it can provide information and direction, whether it is in this area or other areas. I'm thinking now of the ongoing Framingham, MA study on coronary heart disease, other environmental factors. I don't think anybody would claim what we know from those studies have given us causal relationship, but there has been a lot of behavior modified as a result of those findings.

That is what I am simply trying to get at, the magnitude of the information that we have at this moment.

Dr. **Houk**. I made my statement, Mr. Chairman, because you frequently hear that because we don't have and cannot have cause and effect, we can't make decisions.

Mr. **Levitas**. We hear that frequently. We hear it about acid rain and chloroforocarbons and a whole bunch of other things, but we do have to make decisions based upon the best available information.

Could you discuss just for a moment, Dr. Houk, and possibly Dr. Jasanoff who I think may want to contribute for the record, about the long-term effect of exposure to certain chemicals that don't manifest themselves immediately—you swallow it and get sick type of things—but you are exposed over a period of time, and then you manifest certain symptoms that are commonly associated with long-term exposure to that particular substance.

I think this is an area that a lot of people don't understand. I remember when I was in the State legislature and we were debating mirex. A legislator from one of the rural areas of our State who wanted to kill some more fire ants swallowed some mirex to prove conclusively that it wasn't bad for you, whatever the point was, he was trying to make.

As I understand it, there are certain chronic effects that occur after a long period of time, and not necessarily tomorrow morning.

Dr. **Houk**. There are a few diseases, and I believe you can count them on one or two hands, where a specific chemical causes a specific disease, either acutely or sometime down the pike, vis-a-vis—mesotheliomee-asbestos; angio-sarcoma of the liver-polyvinyl chloride, et cetera. But those are very few. It is my view that the risk of our chemical world and risks of the hazardous materials around us increases the risk of the more common diseases we have, increases risk of hypertension, increases the risk of birth defects, increases the risk of cancer, increases the risk of certain liver diseases by exposure to these various kinds of chemicals. And to ferret that out, how much of an increase on top of something that is relatively common, is going to be very difficult.

With the issue of the long-term effects, of being able to measure this, we really have two problems. One is what is exposure? For most of these chemicals, we do not have laboratory tests that can determine if a person has been exposed or not exposed. We must use records and use those very tightly as best that we can.

In addition to that, in this country we do not have a very good system of following people over the long term. Hence, we are establishing some registries to keep track of those individuals. Then if something occurs with a frequency of, say, 2 in 100, for example, and exposure to a material increases that risk by 1, then you have to have a large number of people followed for a large period of time to be able to demonstrate that increased risk, whether it occurred or did not occur.

And I believe for that reason that science is not going to be able to produce the conclusive answers. We are going to have to make our best judgments. We have, as you say, in the Framingham study, changed a lot of behaviors. We have regarding the lead in our environment, we know we have millions, that is an exaggeration, but at least hundreds of thousands of papers on lead. Lead is bad for you. Lead makes our children a little less intellectually capable than they should be. The major source of lead in this country is gasoline lead, from automobile emissions. And the Government has taken action to limit the emissions of lead from gasoline.

I think also that because of the complex problems that we have, one of our real goals in this issue should be to prevent the exposure in the first place, to really address the issue of chemicals. Should they be added? Is there real reason to add this one? Is there enough economic necessity?

If we have to, if a contaminant is produced in the manufacturing process, can we clean that up at best? Or if chemicals such as polychlorinated biphenyls when they burn through accidents, inadvertent events, produce dioxins. Can we prevent that accident? If we can't prevent that accident, maybe we shouldn't allow it in the first place.

Mr. LEVITAS. Dr. Jasanoff, could you just address the same question regarding the long-term effects and so forth, in the context of your statement, and why it is that persons exposed to 2,4,5-T, victims as I would call them, cannot meet, as I understood you to say, even the modified proof requirements of some of the mechanisms that have been put in place to provide compensation for such victims?

Ms. JASANOFF. Obviously, the time gap between exposure and the appearance of a disease like cancer is not the only thing that makes it difficult for this category of victims to meet the standard of proof. But the way that the time lag affects the case is that during the intervening period where victims don't know that they may 20 years down the road end up with this disease, they have no reason to maintain their own medical records. And they have no reason, particularly, to keep track of other exposure circumstances that could eventually in a court of law become intervening causes, and these intervening causes could undermine the case for tying the effect that shows up many years down the line with an exposure that occurred 15 or 20 years ago.

So both for the recordkeeping reason and for the reason that other causes, particularly when we are talking about ordinary diseases of life, may intervene in that period, it becomes very difficult for claimants to make their case.

Mr. LEVITAS. Many complexities. Obviously, someone who has been exposed to a particular substance and may, as a result, manifest a certain illness later on, can get run over by a car and, therefore, never manifest that illness.

I have just one last question in this round, Dr. Houk, and then I will get back to you after the other members have had a chance. In your testimony you note that based upon inquiries from EPA and FEMA concerning the Times Beach situation, under the circumstances there, CDC made the recommendation that the residents not go back to their homes, not go back to Times Beach.

It would be helpful, I know to me, if you could explain just what is the role that CDC plays in matters of this sort. I am constantly hearing that when a situation develops, whether it is at Love Canal or Stringfellow or Seymour, that everybody says, "We will ask CDC to tell us whether the situation is such that we need to have some action response," whatever the action may be.

What is CDC's role in all of this? What do you do? As I understand, what CDC does in this area is of an epidemiological nature, and not the sort of activity that I think you were called on to play in Times Beach. But I may be wrong.

Dr. Houk. That is the CDC of old. And it would be very, very pleasant if that is what our role was. We have a role under CERCLA, a legislative role, relating very specifically to health studies, and to advise EPA on health issues and to determine if there are health issues or if there are not health issues. It is our role under the CERCLA legislation to do the risk assessment. And it is EPA's role to take that and to do the risk management.

I point out that the classic risk assessment is somewhat less precise than 5-year weather forecasting. When we have to use animal data and try to extrapolate it to human, it doesn't mean it can't be used, but it does mean we have to recognize what it is.

We were very concerned, as in the Times Beach issue, as Mr. Young knows very well, that the dioxin in Times Beach had moved because of the flood and people would go back into their houses. Before that could be measured, we made the recommendations that they stay out.

Based upon animal data and assumptions that being exposed to a level of one part per billion dioxin in a residential setting for a lifetime, from children to adult, results in an excess cancer death of about 1 in 100,000, which is a standard risk assessment thing that we use, we do not think that that is an acceptable risk. If it can be prevented, it should be prevented so that you don't have to be faced with that risk.

Other activities, other authorities that we have to respond to are in the Public Health Service Act, in various situations. In the original Love Canal we were directed by the Congress to become involved. I think that one has to use the epidemiologic process and try to balance the risks as best that one can and arrive at some sort of decision of what is acceptable, and what is not acceptable risk by a definition that people could agree upon, and then try to devise ways to prevent exposure to those particular compounds that are already in our environment from happening so that we do not have to have that risk.

Mr. Levitas. But in the case of Times Beach, as I understand your testimony, CDC made a specific risk management decision, or recommendation; that is, don't move people back into Times Beach. There is a site which you may be aware of that has just been identified in Metropolitan Atlanta, the ABC Chemical Compound Co.

After analysis of the chemicals that were discovered there, EPA determined to make an emergency response and action is commencing this morning.

Does CDC get asked the question, "What should we do, CDC? Should we evacuate the people from the neighborhood? Should we dig wells to find the migration, if any, of the chemicals of the site?" What is CDC's role in that regard?

Dr. HOUK. Our role in this, Mr. Levitas, in the emergency responses, I think it is very clear where those decisions are made. For some of the remedial sites that you are talking about we would have a role in helping design the environment monitoring system, the testing system, to ensure that it adequately represents the areas. We would also have an advisory role, to ensure the adequacy of the information, the quality control of the information, to look at the human health effects, the avenues of exposure, the population around it, whether there are potential toxicities to these exposures; and then to make recommendations to EPA.

The Times Beach decision was early in the process of Superfund. And we would probably not word the Times Beach advisory in the same way of saying tell the people not to move back. We would have worded it and said, "Do not allow the people to be exposed to the potentially contaminated soil." There was only one available solution in our view at that time, since the flood, and that was not to allow them to move back.

Mr. LEVITAS. Mr. Sundquist.

Mr. SUNDQUIST. Thank you, Mr. Chairman.

Mr. LEVITAS. Let me say before you begin. Mr. Sundquist wasn't able to be with us yesterday. But on the previous day he chaired a very impressive conference, the Mid-South Conference, on hazardous waste in Memphis. And, based on the people I have talked to who had the opportunity to participate in that, it was extremely important. I want to compliment you on that.

Mr. SUNDQUIST. Thank you, Mr. Chairman, and thank you for your presence at that conference.

Dr. Houk, let me go back a second. Could you give me the numbers again? You quoted figures of 1 out of 100,000 relating to Times Beach.

Dr. HOUK. That was the risk assessment that we used, and that is a fairly common one that is used on asbestos.

Mr. SUNDQUIST. Tell me what that means is what I am asking. Translate that into layman's terms.

Dr. HOUK. It is very difficult, Mr. Sundquist, to put it in layman's terms. I have tried to do this in public meetings and lectures for course 101A in biostatistics, as you can imagine. What this is, is looking at the avenues of exposure, looking at the total lifetime of someone who would take in a particular compound; then looking at the mechanism and action of carcinogenesis, mutagenesis, or whatever, in the animal studies, making the calculations that this does or will produce this many excess cancer deaths in a population.

It is a technique that is used for making decisions, but it is a very difficult technique to explain to people because over and over, I don't care about all your crazy numbers, but what if I am the 1 in 100,000? It means we do not have adequate human data, this is all we have to go on.

Mr. SUNDQUIST. Are you saying if 100,000 people lived in Times Beach, 1 would come down from—with exposure, 1 more than what normally would occur?

Dr. HOUK. We would expect one extra individual to die of carcinoma, which that was based upon, with a lifetime exposure.

Mr. SUNDQUIST. So we moved everybody out of Times Beach on your recommendation or your risk assessment, or you told them not to go back because of only 1 out of 100,000?

Dr. HOUK. We recommended that people should not continue to be exposed to that amount of dioxin.

Mr. SUNDQUIST. Because of 1 out of 100,000?

Dr. HOUK. Yes.

Mr. SUNDQUIST. Now, is that what you would call an environmental exposure?

Dr. HOUK. Yes.

Mr. SUNDQUIST. How would that differ from someone working with dioxin in an occupational exposure? What are the numbers there?

Dr. HOUK. There are no numbers that I know of. The dioxin is not purposely produced. It is a contaminant of the manufacturing process. The exposure of workers to dioxin is quite different than exposure in the general population. More is likely to come through the skin because of the content of it.

In Times Beach we were talking about the dioxin that was available in the soil, that people would breathe in dust, that people would eat the dust, the children would eat through their normal hand-to-mouth activities.

Mr. SUNDQUIST. Would it be less of a problem, then, at Times Beach than it would be for someone who worked with chemicals that had some exposure to dioxin?

Dr. HOUK. I would expect that the exposure of the occupational workers is probably greater than the general population from the environment.

Mr. SUNDQUIST. What do you recommend for those workers receiving exposure through occupational contact?

Dr. HOUK. We would recommend, and I will let Dr. Fingerhut amplify this, but we would recommend to try to prevent that exposure in the first place. If the exposure had already occurred, we'd recommend to do some studies on that.

Marilyn.

Dr. FINGERHUT. At this time, sir, there is no 2,4,5-T or trichlorophenol production being conducted.

Mr. SUNDQUIST. But there has been.

Dr. FINGERHUT. There has been. It is all terminated now. So currently there wouldn't be any exposure by working with the process.

Mr. SUNDQUIST. Have you done any studies on the numbers of those who worked with it?

Dr. FINGERHUT. The NIOSH dioxin registry has a listing of demographic and work history information for, we think, all U.S. production workers who ever would have made those substances and several others. We have identified about 5,000 workers, production workers, to date. And we anticipate identifying possibly an additional 1,000 by the end of this year. So that would be a cohort of all production workers in the United States who made substances contaminated with dioxin.

It doesn't include people who used the substances. And that number we don't have an estimate on.

Mr. SUNDQUIST. Dr. Houk, that would be 1 death per 100,000. What about other body functions or changes in that individual?

Dr. HOUK. We don't know enough about that, Mr. Sundquist, to be able to make predictions. We did our prediction on the things. I think that in the dioxin issue you have the production workers, now one can say with a great deal of certainty that chloracne is caused by dioxin exposure, that there is good evidence that in the acute effect, there is some abnormality of nerve conduction and neurological problems.

In the short term acute thing, there is pretty good evidence that there is an association with altered immune system, and with very high dosage, probably a very firm association with prophyria cutanea tarda, a very specific prophyria that is mediated through the liver. I point out those are very acute effects.

We know very little about the long-term effects and may never know very much about the chronic long-term effects of these chemicals either one way or the other.

If we are looking at adverse reproductive outcomes, let me give an example. The base line against what we are looking at is that people newly married and practicing unprotected intercourse for a year, about 20 percent fail to conceive. Once pregnancy has been diagnosed, about 20 percent end in miscarriage. If the pregnancy is carried to term, about 3 percent are stillborn. Of those who are born alive, 5 percent have structural birth defects detectable during the first year of life, and about 15 percent of birth defects detectable during the first 15 years of life; adverse reproductive outcomes are a relatively common event in people.

If you are trying to add to that, add a 20 percent increase or a 10 percent increase or 5 percent increase, it is almost an impossible task to verify.

Mr. SUNDQUIST. Two more questions.

Going back just a step, can you outline what poses the greatest threat, greater risk to human health? Are we talking about environmental exposure or are we talking about occupational exposure?

Dr. HOUK. Occupational exposure is an environmental exposure. It is an exposure in the environment of the occupation or the environment of where the individual works. Generally if you relate it to chemicals or materials, exposure in the occupational setting——

Mr. SUNDQUIST. How about saying nonoccupational versus occupational?

Dr. HOUK. OK. Generally chemicals, the occupational exposures are higher I believe. That is generally true. There are instances where the chemicals are taken home on the clothes, affect the children, affect other members of the house, et cetera. The occupational exposure to these chemicals generally is as small as the companies can make it.

I mean there are accidents, they are inadvertent. But it is to the interest of the companies very much to have a good safety record, not to have the accident, not to have the adverse health effects to their workers. In the environment in the nonoccupational environment, generally the exposures are lower.

We don't know, however, what the results of those exposures are. Indeed, we don't know how to measure exposure. We do not have techniques of measuring exposure for most of these chemicals.

Mr. **SUNDQUIST**. You said earlier science can't give us the answers. Is it possible to compensate victims of toxic chemicals?

Dr. **HOUK**. Science cannot give you a firm number of—for each case for cancer of something "X" percentage of them are caused by an exposure to "X." That is impossible.

I do not have opinions on compensation. I don't think that is my job. My job is to try to determine associations, where they exist or don't exist. It is up to the public policymakers and others to grapple with these very difficult questions of public policy.

Mr. **SUNDQUIST**. Dr. Fingerhut, is it possible, the same question, to fairly compensate victims of toxic chemicals?

Dr. **FINGERHUT**. I also, work as a scientist. I don't have an opinion on compensation, sir.

Mr. **SUNDQUIST**. Dr. Jasanoff.

Ms. **JASANOFF**. In certain cases I think it is. Dr. Houk mentioned, for example, the known rare diseases that are uniquely associated with certain kinds of exposures, mesothelioma, asbestos being perhaps the best known example. In those cases, I think there is very little doubt when the victim appears demonstrating that symptom that the causal chain leads back to an identifiable exposure. Those are the easiest cases.

I think one can trace from there a continuum across the whole array of people exposed to toxic substances for sure, but in unknown concentrations and demonstrating effect that become more and more like ordinary risks of life. Obviously as you go along that continuum, the problem of compensation becomes very difficult, and there is a large segment at one end where I would say, no, you cannot compensate these people under any reasonably fair theory of compensation.

Mr. **SUNDQUIST**. Thank you, Mr. Chairman.

Mr. **LEVITAS**. Thank you, Mr. Sundquist.

Dr. Rowland.

Mr. **ROWLAND**. Thank you, Mr. Chairman.

I wish to go back to the seven reported cases we talked about earlier. And five were histologically verified.

Dr. **FINGERHUT**. That is right.

Mr. **ROWLAND**. Two were not. What were those two that were not verified?

Dr. **FINGERHUT**. They were carcinomas, sir.

Mr. **ROWLAND**. Mistaken diagnosis?

Dr. **FINGERHUT**. I believe.

Mr. **ROWLAND**. Is that usual?

Dr. **FINGERHUT**. Soft tissue sarcomas are very rare cancers and according to our consultant experts, they are difficult to diagnose in many instances. There are many, there are several dozens of subtypes, as a matter of fact.

In part, I think because of the rarity, there has been great growth in the understanding and designs of classification and diagnosis of these various subtypes of soft tissue sarcoma. So there has been growth in the area within soft tissue sarcoma.

I can't comment on frequency of diagnoses, because I am not a soft tissue carcinoma expert. I am not a physician.

Mr. **Rowland**. I guess what I am asking is that there may be other instances where the disease might be thought to have been due to one thing when it was due to something else.

Dr. **Fingerhut**. Yes; let me talk just for a minute about these seven cases. I think it is important. As I indicated to the chairman earlier, in 1981, the rough estimate from reviewing three company studies with three deaths due to soft tissue sarcoma in them, suggested that there might be, based on national statistics, a possible 40-fold excess in the finding.

NIOSH indicated that what it would do was to confirm the cases, a basic epidemiologic principle we call confirming the cases, means to find out if the case was soft tissue sarcoma and find out if the people were exposed.

When the letter was written, there were three cases known in the United States. In response to that letter to the medical journal, *Lancet,* in 1981, the other four cases were reported by letter to that medical journal.

Case No. 4 was reported by Dr. Ralph Cook of Dow Chemical Co., who said the person had soft tissue sarcoma and was a member of one of the Dow cohorts that had been reported. But he was alive, so was not included in this mortality study. Now, since that time, that person died. So, of the seven cases, four of the cases belonged to the four studies. Three additional cases were reported by their physicians who had seen them in their offices and so knew they had soft tissue sarcoma and knew they worked at a facility where the herbicides were made, but didn't know necessarily the location of the work.

NIOSH indicated it would perform basic epidemiology, confirm the cases. Did these seven people have exposure? Did these seven people have soft tissure sarcoma? And that is what we have described here in the testimony.

Now, the numbers were small. Originally, three were written about in 1981 in the four company studies. It turns out that of those three, one has pathologically confirmed soft tissue sarcoma, but case No. 4 from those four company studies also has soft tissue sarcoma.

Now, we have a situation, you see, where we still have small numbers. In the 1981 letter it was reported by the companies from death certificate information that three people had soft tissue sarcoma. When you use death certificate information, you can compare the information on the death certificates to information in national statistics because we get our population rates from death certificates.

So, the original comparison of .07 percent of deaths expected was from national statistics which are based on death certificate information.

As a result of this current review which we have done, which involved getting the death certificates, getting the original hospital reports, getting the tissue specimens for these seven people and having the tissue specimens reviews by soft tissue sarcoma experts, our conclusion now is that of the four people who were reported from deaths certificate data by the companies to have exposure and soft tissue sarcomas, we have confirmed that they have exposure, but upon pathologic review our experts say that two have soft tissue sarcoma, not four.

Of the other three, they have soft tissue sarcoma pathology, but their records don't show that they ever worked in the 2,4,5-T, or trichlorophenol.

Now, the situation is, of the four who have exposure and originally were reported as having soft tissue sarcomas from their death certificates, we know there are two pathologically confirmed in that group.

Is that an excess, I think is the question? And what we have concluded is that it seems that two is still more than we would have expected. However, we still have small numbers and the comparison is a little bit rough now, because we have ascertained the cases by pathology review from experts and we are comparing them to death certificate information in national statistics. So we can't make that comparison. It may be apples and oranges. But it may be accurate.

So, our conclusion is that two is a small number. Two seems to be more than we would expect. What must be done is the large study which is underway. And so we are proceeding.

Mr. ROWLAND. Thank you for that explanation. I want to ask something about dioxin and its half-life. I understand it is very photosensitive.

Dr. HOUK. Dioxin, if it is exposed to ultraviolet light, we are talking about 2,3,7,8-TCDD now, the most toxic form, will, as was the overall spraying on the trees, et cetera, its half-life is relatively short.

But when it gets into soil and when it is protected from ultraviolet light its half-life was said, the liturgy was a rather precise 200, and I think 36 days. We know from Missouri that it stays there at least 13 years. And if it is there for a decade, it is probably going to be there for centuries.

That will have to be our assumption since it has not deteriorated in that period of time. I would like to make a point of differentiating some of the past exposures that have happened, and it seems to me a major emphasis we should be placing on preventing future exposures.

Because the past exposures really have gotten us into a very complex, difficult kind of issue. And we may be able to prevent something. And without fixing any blame or even laying blame, I would point out that had the materials from the manufacturing plant, dioxin-containing materials, been appropriately disposed of in Missouri, we would not have the Missouri dioxin problem that we have today.

Mr. ROWLAND. 236 days half-life, would that still constitute, in your opinion, a severe hazard?

Dr. HOUK. We know the half-life of dioxin in soil will be measured in the decades, and probably a lot longer than that. It has shown from the horse arenas in Missouri where it was measured in 1971, and again in 1983, substantially no deterioration in the amount.

Mr. ROWLAND. Did I understand you to say that the decision was made to move the people out of Times Beach after the flood?

Dr. HOUK. Yes, the flood, that led to the decision to move the people out of Times Beach. They were moved out because the town was flooded. It was our recommendation because we were very much afraid, we had samples of dioxin into the hundred parts per billion—200, 300 parts per billion, if I believe correctly, was the highest.

We did not know what happened to the dioxin soil as a result of the flood. We were very much concerned that it had moved into the houses. That was our recommendation then, to EPA, not to have the people come back in. We would not make that recommendation again in those precise words.

The same results would be accomplished. We would probably say keep them from being exposed. And there is only one way you could do that, and that was not allow them back into their houses.

Mr. ROWLAND. Had the flood not occurred, would you have made that recommendation?

Dr. HOUK. Had the flood not occurred, we made the recommendation on Minker-Stout, which has dioxin up to 7, 800 parts per million in the residential area. The recommendation we made on Minker-Stout is that the people not be associated with that dioxin-containing soil.

Mr. ROWLAND. Then you would have made the recommendation anyway.

Dr. HOUK. Yes.

Mr. ROWLAND. Thank you, Mr. Chairman.

Mr. LEVITAS. Thank you very much, Dr. Rowland.

Mrs. Johnson.

Mrs. JOHNSON. Thank you very much.

Dr. Houk, on something you just said in your last statement, when you say people being associated with dioxin-related soil, Does living in a house, walking on the sidewalk, associate one's self with that soil?

Dr. HOUK. Yes. if you have a family and there are youngsters playing outside in the dirt, this is a major avenue of exposure of children because they do things children are supposed to do, explore their environment.

Mrs. JOHNSON. I appreciate that, but if you live in such a way, are you saying that you don't come in contact with the soil, that there is no danger?

Dr. HOUK. Yes, I believe that if you can separate the individual from any potential contact with that soil, then that soil does not make a hazard.

Provided that it is not volatile, comes up in the air or move into the water systems.

Mrs. JOHNSON. Then lastly, just to go back to a point that both you and Dr. Fingerhut have discussed in a number of different ways, in talking about the results of this study, and the fact that there were really two verified cases which does appear to be twice the expected experience, nonetheless in a study that is so limited, with such small numbers. Do you take this as an indication that we must do more research, or can you really base actions on this narrow study?

Dr. HOUK. The two verified cases of soft tissue sarcoma occurring in the two people that we know were exposed to those products give us more concern and have given NIOSH the impetus to proceed very rapidly with the 6,000 worker study to look at their causes of death.

I believe that it is hoped all the people will be registered in October or December of this year, and it is hoped the initial mortality study will be out, I think, in a year.

Dr. FINGERHUT. Mid-1985.

Mrs. JOHNSON. You are going to use the same registry?

Dr. HOUK. Yes.

Mrs. JOHNSON. Well, now, the registry apparently has registered all those workers who are known to have been potentially exposed to dioxin. It does refer here to a couple of cases. Then when you looked at them, they actually weren't exposed.

Are you going to do any work beforehand to find out which of these workers were exposed and weren't exposed before you go further?

Dr. FINGERHUT. The seven workers didn't come from the NIOSH registry. There is, I think, a little bit of confusion there.

Mrs. JOHNSON. Oh, all right.

Dr. FINGERHUT. NIOSH began this registry in November 1979 to identify production workers. As a part of this process, careful review of the literature was important. So the researchers were reading very carefully literature that was published.

We began work on the registry in 1979 and in 1980, four company studies were published in which three of the studies, each reported one soft tissue sarcoma. The NIOSH researchers looking at those studies knew that two major Swedish studies in 1978 had indicated there was an excess risk of soft tissue sarcoma.

Here are four U.S. studies, three of which each contained one death. One can never conclude anything from one death. If one puts the numbers together and looks at the whole picture, one sees three deaths out of 105. That seemed to be excessive. In 1981, NIOSH researchers reported that observation to the medical journal, *The Lancet*.

In response to the NIOSH letter, those other four people were reported by others into the medical journal, The Lancet. So what NIOSH has done recently is to find out whether the seven persons really had soft tissue sarcoma and were exposed.

Now, alongside of that effort, NIOSH has been putting together this production worker registry of 6,000 people. Our effort is still in the data collection phase, and we anticipate having identified all U.S. production workers by the end of this year. As we find the individuals, we proceed with a stage called followup to determine their vital status.

The first use of these data will be a mortality study which should be completed in the middle of 1985, which will look at the causes and numbers of deaths in the 6,000 U.S. production workers, and ask the question, are the causes and numbers different from what one would expect, based on the U.S. national statistics?

So, the registry and mortality study are underway at NIOSH. Review of the literature and confirmation of reported soft tissue sarcoma cases in the literature is also an activity. Now, I think the reason for some existing confusion is that the sarcoma cases who are production workers also are in the NIOSH dioxin registry, among the 6,000 workers, if they worked in the processes that we are collecting information on. There has been some confusion in saying that the sarcoma cases came out of the registry. Actually, they didn't.

Mrs. JOHNSON. The three studies you referred to were scientifically accepted?

Dr. FINGERHUT. Yes; these were published in the Journal of Occupational Medicine in 1980, by two companies that make the herbicides. We received the fourth in draft form in 1980, but it has been published recently in the literature.

Mr. LEVITAS. While Mrs. Johnson is framing her next question, I will announce that there is a quorum call in process on the floor which may be followed by a 5-minute vote, if ordered.

So I thought maybe if Mrs. Johnson had one more short question, with hopefully a short answer, we might take that, then recess briefly so we can be recorded, and vote, if necessary, then come back and try to complete this panel of witnesses before we break for lunch.

I know Mr. Young has some interest in the Times Beach aspect of this at the very least.

Mrs. JOHNSON. OK. I hope you can make a brief response. First of all, have you started the registry of the Times Beach people?

Dr. FINGERHUT. The workers at the Verona, MO, plant, where they made the hexachlorophene, are included in our registry. The environmentally exposed people are not.

Dr. HOUK. But there is a registry of the Missouri dioxin folks that is separate.

Mr. LEVITAS. Can I clarify that? Is that a separate registry for the Missouri exposed victims?

Dr. HOUK. It would be a registry for the environmentally exposed people of dioxin, most of them are from Missouri now. It will spread to other States where there is other contamination.

Mrs. JOHNSON. As opposed to worksite exposure?

Dr. HOUK. Yes.

Mrs. JOHNSON. Dr. Jasanoff, two questions. First, do you have any comment on the differences or strengths and weaknesses of the 2-tier compensation approach recommended by the section 301(e) Superfund study group, and the collective liability proposal in the NSF study?

Ms. JASANOFF. I have not followed the section 301(e) proposals in enough detail to be able to give you a quick answer on that.

Mrs. JOHNSON. Would you be interested in taking a look at that and seeing if you have any thoughts on that?

Ms. JASANOFF. Yes.

[The information received from Ms. Jasanoff follows:]

SUPPLEMENTARY STATEMENT OF SHEILA JASANOFF

Both the National Science Foundation (NSF) victim compensation report and the Superfund § 301(e) Study Group proposed a two-tier approach to compensation. Differences between the two proposals can largely be attributed to the timing of the two studies and to their divergent objectives. The NSF report was based on case studies carried out in early 1981. Its primary objective was to evaluate the scientific basis for compensation decisions in relation to existing mechanisms. The § 301(e) study, completed more than a year later, was concerned with making new policy recommendations to supplement available remedies. Accordingly, the proposals in the later study were worked out in considerably greater detail than the collective liability approach outlined in the NSF report. For these reasons, I do not believe an in-depth comparison of proposals in these two reports would be very fruitful.

There are, however, two conceptual differences between the NSF and § 301(e) Study Group proposals which I think are worth highlighting. They relate to the design and accessibility of the Tier Two remedy, and in each case I believe the § 301(e) proposal is the more advantageous. Let me briefly describe the discrepancies and explain my evaluation.

The Superfund Study proposed that the Tier One administrative compensation system should be supplemented by a Tier Two consisting of currently available state tort remedies in the fifty states, modified to remove specific procedural and other barriers to recovery. By contrast, the NSF collective liability scheme made a new federal cause of action available at the second tier as well as the first. In this system, different rebuttable presumptions operating at the two tiers would require the plaintiff to meet a higher burden of proof in second tier actions against named defendants. However, even in such cases, the plaintiff would not need to demonstrate that the defendant was the cause of his injuries in order to recover. Existing tort remedies in most states would not permit recovery under these circumstances. The Superfund Study recognized the need for reform in this area. But instead of proposing a uniform federal rule or rebuttable presumption, it recommended that states should revise their rules so as to hold potential contributors to injury or damage jointly and severally liable, placing on multiple defendants the burden of allocating responsibility among themselves.

Federalizing Tier Two would have the advantage of creating a nationally uniform compensation system. Against this, however, must be set the costs and uncertainties of setting an entirely new remedial process in operation, particularly one involving the interpretation of new legal rules. The cost of compensating victims under a uniform, relaxed standard of proof in Tier Two is especially difficult to predict in advance. Retaining the state tort remedy at the second tier, as proposed in the Superfund Study, would not only prevent sudden dislocations in the number and size of claims, but would permit healthy experimentation in the states with new approaches to the problem of collective liability. Moreover, if a clearly superior approach were to emerge after a period of varying state activity, it would always be possible to amend the federal compensation process to create a uniform Tier Two remedy based on the most successful state model.

The Superfund Study compensation proposal promises to be less costly than the NSF collective liability system in another respect as well. The § 301(e) Study Group was concerned about increasing the administrative costs of victim compensation by simply adding a new remedy to those already available. Members recognized that the entire victim compensation process could become hopelessly unwieldy and expensive if claimants could freely elect to pursue both Tier One and Tier Two remedies. The report proposed at least two types of entry barriers to Tier Two for claimants electing Tier One: either an "exit toll," subjecting the claimant to an assessment of costs for unsuccessfully pursuing Tier Two, or enhanced benefits at Tier One, including recovery for certain kinds of pain and suffering, so as to make this "normally" the exclusive remedy for most claimants. These mechanisms have no analogues in the more rudimentary two-tier process outlined in the NSF study. It seems clear to me, however, that federal victim compensation legislation following the two-tier approach should include some means of alleviating the problem of the add-on remedy identified in the Superfund Study.

This concludes my appraisal of the relative strengths and weaknesses of the NSF and Superfund Study compensation proposals. Thank you again for the opportunity to present my views on this extremely important subject.

Mrs. JOHNSON. Fine. Thank you.

Lastly, Dr. Jasanoff, the report that you discuss recommends compensating victims for their severe stress, in the absence of physical manifestations of injury.

Now, we have found here that the data around the issue of physical manifestation isn't very strong. It seems to me that the issue of stress is one that could be claimed in many, many situations.

And I wonder if you could give me some better understanding of why you would recommend compensation on the basis of severe stress?

Ms. JASANOFF. As I stated at the end of my prepared testimony, what was represented in the testimony was my personal opinion and not that of the National Science Foundation. So I must also disclaim personal credit for everything that shows up in the NSF recommendations, because that was based on three different case studies conducted by three different people.

I don't believe, in fact, that compensation proposals in which people would be compensated for stress alone are a realistic way of going about it, any more than, for example, the use of purely psychological symptoms to base regulatory decisions on was considered appropriate by the Supreme Court following the Three Mile Island incident.

Mrs. JOHNSON. Thank you very much.

Mr. LEVITAS. Thank you very much.

The subcommittee will stand in recess for 15 minutes.

[Recess.]

Mr. LEVITAS. The subcommittee will please come to order.

The Chair recognizes the gentleman from Missouri, Mr. Young.

Mr. YOUNG. Mr. Chairman, I want to thank you and the committee for allowing me to participate this morning. I don't know if Mrs. Johnson had a chance at the end of that question, to Dr. Houk I guess it was, about the psychological effects.

I know in your statement, Doctor, that was not a part of your study, isn't that right?

Dr. HOUK. Yes, sir.

Mr. YOUNG. Why was that left out? I am trying to remember back to the middle of February.

Dr. HOUK. The study was done so rapidly in response to the concerns of the citizens there, that it was the judgment of ourselves and everybody that we called in, that the instruments of the study were not sufficiently valid and therefore any results obtained and disseminated would probably be harmful.

We are grappling with that issue, Mr. Young, for the future, if some instruments can be designed to be able to measure that.

Mr. YOUNG. Just one question I have, Doctor. We have gone through this. You briefed me on October 16 of this year. As you had indicated earlier, the CDC had warned the State of Missouri back over 10 years ago, I think you said 1971 or 1972, that dioxin was the cause of all the deaths of the horses and other farm animals that died in a very short time period.

Why did not, or did CDC then realize that the health studies on humans should have been immediately started so that here we could be maybe 10 years down the road a little better involved on the search and data that could have been gathered over that time?

Dr. HOUK. When the original study of the Shenandoah Stables and stables in Missouri where all the horses died, and the chickens and the little girl got sick in 1971, we knew that the material in that soil was some of the most toxic that we had seen.

We did not know what it was. In fact, it was not until 1975 that further studies at that time demonstrated that the material was dioxin. We made a recommendation then that the sludge in that tank be appropriately disposed of and appropriately burned.

As you probably remember, Mr. Young, there is a great deal of difficulty getting permits across State lines for that to go where the incinerations were, and people not wanting it passing through in their State.

Why that did not happen, I don't know. I doubt, sir, whether we would have recommended at that time a health study, because then in—the liturgy was that the half-life of dioxin in soil was less than a year.

And so, it had been placed there in 1971. Then, it was 1975 when we found out what it was. So, therefore, it had been reduced and it was probably not important to go back and do that.

The other thing I think, and this also partially addresses some of the chairman's concerns, that the environmental health issues in the Center for Disease Control are relatively new.

The Center for Environmental Health was established, I believe, in 1980. There were some little activities going before that, but not major, great activities.

Mr. YOUNG. At that time, then, in 1975, I didn't realize that, Doctor, was the organization aware of Mr. Bliss' activities?

Dr. HOUK. No, sir.

Mr. YOUNG. Fine. Thank you very much.

Thank you very much, Mr. Chairman. I appreciate that.

Mr. LEVITAS. Thank you, Mr. Young. I appreciate your continuing interest in this. Dr. Houk, you were talking in answer to Mr. Sundquist's questions about the use of 1 death per 100,000 as a threshold level for unacceptable risk. Are there different levels of risk per 100,000, or whatever number, for different types of activity, or different types of risks that people incur?

For example, 1 death per 100,000 in the case of exposure to a chemical is one we have talked about. Would that be the same level for driving across town in your automobile, or having a heart bypass operation or smoking cigarettes?

Dr. HOUK. By no means, Mr. Chairman. The risk that some of us unfortunate ones continue today, like smoking cigarettes, is probably one of the greatest risks to our long-term health, not only for bronchogenic carcinoma, but for heart disease, chronic lung disease, a whole host of different things.

The risk of driving, of being injured in event of an automobile collision, if you don't wear your seatbelts, you markedly increase that risk. You can eliminate the risk of—essentially eliminate the risk of toddler deaths in automobiles by having all the toddlers and the young kids in the appropriate child restraint device.

These sorts of risks are voluntary risks that people take. As I travel the country and deal with these issues, the unacceptable risk to the American population is the risk that is imposed upon them by somebody else.

Mr. LEVITAS. The study that you referred to, Dr. Fingerhut, or that Dr. Millar had referred to in his testimony, concerning the lumberjacks, where was that reported in the literature?

Dr. FINGERHUT. They were reported in Swedish journals and also in the Scandinavian journal, Work Environment. I can give you the references. I have them in my briefcase. They are usually published in Swedish and then again in an English journal.

Mr. LEVITAS. I recall, and I haven't been able to put my finger on it yet. I am going to ask staff to look for it in Dr. Karrh's testimony. He testified at our last series of hearings. He is with the Du-Point Co. and was testifying on behalf of the Chemical Manufacturers Association.

I am going to ask some questions about that testimony. But there was one particular point that he made, as I recall it, that there were no reported scientific medical studies of injury from occupational exposure to dioxin.

I believe that was the substance of what he said.

Dr. HOUK. The statement is incorrect. Let me be as blunt as I can. In the acute exposures, there is association of dioxin and chloracne. Chloracne is something other than just childhood acne.

In the Seveso incident, which people keep referring to as chronic exposure, it is not. It is acute exposure. Numbers of those children had abnormalities of their nerve conduits. Numbers of those children had problems with logic when they were tested.

In the adult population of workers in this country, there have been problems identified of immunologic difficulties. And there have been in the acute exposure and for a short term afterwards, and there certainly is a very strong association with prophyria cutanea tarda.

One of the difficulties, Mr. Levitas, when we talk about dioxin, and I don't want a dioxin hearing, is that there are 75 compounds that are generally referred to as dioxin. And these vary in toxicity from almost nothing to among the most toxic compounds that we know in this country.

It is also said that you produce dioxins when you barbecue your steak in your backyard, which is a true statement. But you produce the kind that aren't toxic. You don't produce 2,3,7,8-TCDD. I think that statement from the DuPont witness is in error. I have said so before other committees.

Mr. LEVITAS. Now, in this Swedish lumberjack case, there was evidence, I gather, from what I read, that exposure over a period of time by these lumberjacks to this material apparently did result in some associated illnesses.

Is that a fair statement?

Dr. FINGERHUT. There were actually three occurrences. In about 1977, in a clinic where lumberjacks were treated, it was noted by the physicians there that there were several cases of soft tissue sarcoma.

That was surprising because it is a rare cancer. That stimulated the conduct of two separate full-scale epidemiologic studies. The design of those studies was different from the ones we have talked about so far, so let me just explain them.

It is called the Case Control Study. Each of them had a similar design. One was in northern Sweden where there were many forests, the other in southern Sweden where there is agriculture.

The design is to use the cancer registry to select male cases of sarcoma recorded in the registry between 1970 and 1977. Those were the cases. The researchers then used the national population registry and selected three controls for each case, who were matched by age, sex, race, and location.

In the first study, there were 50 cases and 150 controls. In the second study, there were 100 cases and two controls for each person. What they then did was to use a questionnaire approach, which inquired about all facets of the person's activities and work exposure and environmental exposure and so on and so forth.

Using epidemiologic methods of analysis, what they learned and what they reported was that people who had prior exposure to phenoxy acids and chlorophenyls had a five-fold increased risk of getting sarcoma, as compared to people who didn't have prior exposure to phenoxy acids or herbicides. The information on phenoxy acids was obtained by asking people, did you use this, where did you work, et cetera.

The two studies are respected epidemiologic studies. They have been critiqued by many peers in part because of the EPA hearings on 2,4,5-T in 1978. There is a range of opinions from one extreme to the other, regarding the studies but in general, they are considered to be solid epidemiologic studies, with flaws, which all studies have.

Mr. **Levitas**. When EPA banned the spraying of some herbicide out in the Northwest, did CDC or NIOSH participate in the science that led to that decision?

Dr. **Fingerhut**. I was not with NIOSH then, sir. I can't speak to that.

Dr. **Houk**. I do not believe so. That is 2,4,5-T early in 1975, something like that. Perhaps 1977.

Mr. **Levitas**. I recall that Dr. Karrh also testified that he would have no hesitancy about moving himself and his family and children into Times Beach. Would you like to be a neighbor of Dr. Karrh at Times Beach?

Dr. **Houk**. I would not under any circumstance conceive and raise a family in the conditions of many of the sites that there are at Missouri. This is the difficulty we face in Missouri. And Mr. Young knows this as well as I do. Both of us have discussed this.

The poor people in Missouri don't know what to think. You have one group coming in, saying you can eat the stuff and it has never caused any harm to anybody. You have another group coming in saying, if you are within 1,000 miles of one molecule, you are going to die tomorrow.

Obviously, the truth lies somewhere in between. We can prevent, we can prevent exposure if we handle the soil in Missouri correctly. We can prevent the future availability of dioxin-contaminated products if we no longer allow the manufacture of products that can do that.

We still may have some, through inadvertent fires, polychloride biphenyls and a few products like that that are going to be around.

One of the issues is to prevent exposure of people. As you know, we are embarking on the study of agent orange for the Vietnam veterans. And people try to relate these two issues and they are not relatable. We cannot prevent the exposure to agent orange that happened 10 years ago or 15 years ago in Vietnam.

We can; however, prevent future exposure to people living in dioxin-containing soil, in future industrial accidents, these sorts of things.

Mr. LEVITAS. I just have two final questions.

Does it make any difference if exposure to a toxic chemical occurs in a workplace, or in a neighborhood that is adjacent to a toxic waste dump?

Dr. HOUK. As to the disease outcome? No.

Mr. LEVITAS. And with respect to the Seveso data, has CDC done any analysis of it?

Dr. HOUK. We have been trying our best over several years, both NIOSH and ourselves, very unsuccessfully to get the raw data to do an analysis of those results. There is a very serious question as to the validity of conclusions when data are unavailable for examination. It is better the way we do things, as in the Missouri dioxin study, that as soon as all data are arrayed we will make public access tapes so any scientist can have that data and analyze it in any way the scientist wants to.

One of the problems of Seveso that we have is the number of dead animals that were brought in assumed to be contaminated. The fact is people were paid, residents were paid to bring in dead animals. No one ever analyzed those animals for body content of dioxin, so we have no knowledge of how many of those animals were killed. We do know that the people living now, the soil in Seveso is contaminated with dioxin at 0.15 parts per billion, which is 7 times lower than our action level we established for Missouri. We do know that, I think 40, or an *x* number of drums, I will not say how many of them from that accident, turned up in France in some butcher's backyard shed that have now been found and put back into the appropriate system. I think the primary basis for our concern is data from the animal models indicating that these compounds do cause harm.

Frequently people will give a very nice liturgy of the animal toxicological data and then follow by saying but that has not been shown to be true in humans, technically an accurate statement but a very misleading statement because the truth of it is, the adequately designed studies in humans have not been done. For various complex reasons they may never be able to be done. Then you have to rely on the animal data and the inadvertent exposures in industry or outside of industry.

Mr. LEVITAS. I remember several years ago there was a substance known as kepone. Was that a dioxin-type compound?

Dr. HOUK. Kepone is a pesticide and I would have to submit information on that for the record. I do not know all of the toxicity to kepone off the top of my head, but it is not a dioxin compound.

[The information received from Dr. Houk follows:]

Kepone is a persistent chlorinated aromatic pesticide of moderate acute toxicity. In humans, the following toxic effects have been observed: tremors, rotating eye movements, and reversible effects on male reproduction. In rodents, it has been shown to be a carcinogen and to affect reproduction. Kepone is entirely chemically and toxicologically unrelated to the dioxins. The only similarity is its lipid soluability and the fact that it is preferentially stored in adipose tissue and liver.

Mr. LEVITAS. I am going to——

Dr. HOUK. It is not a safe compound.

Mr. LEVITAS. I am going to ask you to work with our staff. I would like some additional information about Seveso. It may be that we, this committee, the Congress, working through the State

Department, might be able to get some additional information. I am very interested in pursuing that situation. So I would like for you and our staff to get together on that. I do not have any further questions of the panel at this time, except let me say that I want to express my appreciation to all three of you for your being here today. You have answered a number of questions that I felt needed to be addressed from experts such as yourself. I would like to, on behalf of myself and the rest of the subcommittee, express my appreciation to you. Thank you very much.

The subcommittee will be in recess until 1:45 p.m.

[Whereupon, at 12:35 p.m., the subcommittee recessed, to reconvene at 1:45 p.m., the same day.]

Mr. LEVITAS. The subcommittee will please come to order.

This afternoon we have a panel of witnesses to address some of the concerns that industry has with respect to this issue. It has been my purpose to seek input from every possible source of every interested group and person. And I would like to join in the remarks that Congresswoman Johnson made this morning. I am especially grateful for the participation this afternoon of Mr. Browning and Mr. Kusch, because we need to get the particular expertise that you will bring to us from your perspective.

The witnesses this afternoon are Jackson B. Browning, director of Health, Safety and Environmental Affairs, Union Carbide Corp., and Albert Kusch—am I pronouncing that correct?

Mr. KUSCH. Kusch.

Mr. LEVITAS. Albert Kusch, vice president of Atlantic Richfield Co., senior vice president for manufacturing, research and engineering. Mr. Kusch is accompanied by Gary E. Kovall, manager, environmental, legislative, and regulatory affairs, and Joan DiNal—is that pronounced correctly—DiNal, senior counsel, environmental affairs, of Atlantic Richfield Petroleum Products Co.

We welcome all of you here today and look forward to your testimony. Why don't we begin, Mr. Browning, with you and then we will hear from Mr. Kusch?

TESTIMONY OF JACKSON B. BROWNING, DIRECTOR, HEALTH, SAFETY AND ENVIRONMENTAL AFFAIRS, UNION CARBIDE CORP., DANBURY, CT; ALBERT W. KUSCH, VICE PRESIDENT, ATLANTIC RICHFIELD CO., SENIOR VICE PRESIDENT FOR MANUFACTURING, RESEARCH AND ENGINEERING, ARCO PETROLEUM PRODUCTS CO., LOS ANGELES, CA, ACCOMPANIED BY GARY E. KOVALL, MANAGER, ENVIRONMENTAL, LEGISLATIVE, AND REGULATORY AFFAIRS, ARCO PETROLEUM PRODUCTS CO.; AND JOAN DiNAL, SENIOR COUNSEL, ENVIRONMENTAL AFFAIRS, ARCO PETROLEUM PRODUCTS CO.

Mr. BROWNING. Thank you, Mr. Chairman.

Union Carbide is a diversified manufacturer of chemicals and plastics, consumer goods, industrial gases, carbon products, and many other specialty products.

I appreciate the invitation to testify before the subcommittee on the issue of compensating people injured by exposure to hazardous wastes. This is one of a number of important issues before the Congress which we at Union Carbide are following through corporate policy groups as well as through trade associations.

Our view of the potential health effects and compensation issues associated with exposure to hazardous wastes continues to evolve. These are unusually complex scientific, legal and policy issues for which there are no easy answers. On some points, however, our position is clear.

We support the ongoing efforts under the Superfund law to undertake promptly appropriate cleanup of hazardous waste sites. And we are willing to pay our fair share of the cleanup costs at those sites at which we disposed of hazardous substances. We take this position even though our actions at those sites were not in violation of laws in effect at that time. Timely and effective cleanup efforts serve to protect the environment as well as help to minimize any risk of exposure of the public to potentially harmful substances.

We are committed to minimizing the risk of exposure to these wastes in other ways as well. We currently recycle, reuse or reclaim over 80 percent of the hazardous wastes we generate annually. We are continually seeking new ways to further reduce waste disposal through process improvements, increased recycling, and so on. We also believe additional economic incentives can be used to further the goal of source reduction and encourage alternatives to land disposal.

Most important would be replacing the current feedstock tax under Superfund with a waste-end tax. Such a tax on wastes disposed of, rather than on chemical feedstocks, would, we believe, provide direct economic incentives to complement other environmental statutes which encourage resource conversation and minimize waste generation and disposal. We strongly support such a change to the Superfund law.

We are committed to the proposition that anyone injured by exposure to hazardous wastes should be justly compensated by those responsible.

A key question is defining in scientific terms the health problems associated with exposure to hazardous wastes. There has not been epidemiological or other scientific evidence which supports the need for broad compensation legislation for hazardous waste exposure. Nor have large numbers of injured parties been identified.

The number and nature of injuries are important considerations in determining the need for and characteristics of a new system of compensation. Consideration of existing remedies is also important. In several instances where injuries have been claimed, the tort system has provided compensation. It is imperative that Congress determine that there is a verifiable need for legislation before it takes any action.

With the need for hard facts so critical, we do see the public and congressional debate on the issue serving an important purpose. Through the efforts of many groups, including the scientific community, the administration, the chemical industry, environmental groups, the legal progress, Congress, and many others, we look forward to some better insights in the coming year.

You have heard from previous witnesses regarding efforts to review the available body of scientific information and the data available from known exposure incidents to provide a sound basis for any major legislative action. The Universities Associated for Research and Education in Pathology, or UAREP, study commissioned by the Chemical Manufacturers Association, for example, will be a comprehensive review of available scientific literature to provide better guidance as to the nature and extent of possible health effects associated with exposure from waste sites. The results of the study shall be available next summer.

The Department of Health and Human Services, through its Agency for Toxic Substances and Disease Registry, has agreed to the terms of a court order and will provide needed information in the next year as follows: Information on methods of reporting of diseases and for establishing appropriate registries of persons exposed to toxic substances through environmental exposure; information on health effects of toxic substances organized in a readily accessible data base for all to use; and a list of areas closed to the public or otherwise restricted in use because of toxic contamination.

Efforts such as these will make policy decisions better informed.

While we await information on the extent and nature of the health problems associated with hazardous waste sites which may show the need for compensation legislation, we at Union Carbide continue to look broadly at the policy and legal issues from the two different perspectives. First, what are the key policy and legal issues which we must consider in developing a corporate position, but which cannot be decided until the scientific community better determines if there are health problems associated with hazardous waste sites? Second, what are the key policy and legal issues which should be considered and addressed independent of the extent and nature of the problem?

Let me begin by first highlighting some of the most important of those policy elements which are tied to these scientific questions which we are looking at. Our view is that the present tort system will probably continue for some time to be the principal means for handling claims arising from exposure to hazardous wastes.

We do see a need within that system to improve the basis for making decisions on the critical issues of causation. One recently suggested approach which we are exploring and which is promising is the use of independent expert witnesses to assist the courts on the complex questions of causation.

The traditional authority to call upon expert witnesses could be formalized, for example, to establish a body of scientific experts knowledgeable on the hazards of a particular substance or evaluating site-related exposures. Kept current, this would assure court access to current scientific knowledge. We are not suggesting the outside experts replace witnesses called by the parties involved but rather provide an independent and impartial source of expert testimony.

Exclusivity of compensation, is another very important issue we are looking at. At some point it may be determined that there is a public health problem arising from hazardous waste sites that is sufficiently large and complex to warrant some sort of new compensation system. At that time we will have to come to grips with the question of exclusivity and the continued role of the tort system. It seems to us at that point a decision must be made on the compensation that is to be provided for various injuries and how it is to be provided. In a given situation a potential claimant with injuries arising from hazardous waste exposure should be able to obtain reasonable recovery in a reasonable period of time. However, the compensation for that claimant should be an exclusive remedy.

On the second key point—policy issues to be addressed independent of an understanding of the health problems—there are at least two which we believe should be considered at this time.

The first of these deals with the question of statutes of limitations. Virtually all States have adopted a statute of limitation for tort claims which ensures an opportunity to consider claims for injuries manifested long after initial exposure by requiring only that such claims be filed within a certain period. However, a few States do not base their statutes of limitation on the discovery of injury. We believe this is an unwarranted barrier to recovering for injuries resulting from exposure to hazardous waste. However, we also believe that efforts to remove this barrier should be left for the few State legislatures involved.

The other policy issue to be addressed at this point is minimizing generation and disposal of hazardous wastes, which I have previously discussed. In this regard, again, we believe action by the Congress to replace the Superfund feedstock tax with a waste-end tax is particularly important.

Both of these issues can and should be addressed independent of the extent of health problems tied to hazardous waste. The actions we propose are constructive steps we are prepared to support at this time. We will continue to evaluate the other policy elements associated with hazardous wastes which we believe are so dependent upon the answers from the scientific community.

Thank you for this opportunity to testify. I would welcome your questions.

Mr. LEVITAS. Thank you very much. We will have some questions.

Mr. BROWNING. Very good.

Mr. LEVITAS. Mr. Kusch, if you would.

Mr. KUSCH. Thank you, Mr. Chairman.

My comments today will closely parallel those presented on June 29 of this year before the Subcommittee on Commerce, Transportation and Tourism of the House Energy and Commerce Committee.

As you have already indicated, I have brought with me two colleagues today, Joan DiNal, senior counsel, environmental affairs, and Gary Kovall, manager of environmental legislation and regulatory affairs for ARCO Petroleum Products Co., to aid me in addressing any questions you may have.

I have been associated with the petroleum industry since 1941, and have been privileged to have been party to the tremendous technical and economical changes to our industry which have taken place during that time. We, and other industries, are now entering another era of change, of which the subject of today's discussion is a potentially significant part.

Atlantic Richfield Co. has for some time had under consideration the issue of compensation for exposures to hazardous substances.

We have attempted to develop a corporate position responsive to several key points. However, due to the complexity of this issue, we have not yet reached a conclusion on determining a company position on all aspects of this issue. Our efforts to date have identified several important considerations with respect to the need for victims compensation legislation.

First, we recognize that there is a public perception that environmental exposures to toxic substances present a significant human health risk. Second, as a cardinal principle, we believe that injured persons should be fairly compensated by those responsible for the harm. Third, any legislatively established compensation system must include clear guidelines upon which industry can rely and plan its activities. Fourth, we find that the dimensions of the problem of environmental disease are poorly defined. This leads us to conclude that passage of legislation to compensate persons for non-work place exposures to hazardous substances is premature.

Further, it is difficult to identify causation and to create a compensatory scheme which isolates the cause of disease and allocates responsibility for harm.

There may be instances where toxicological and corroborating epidemiological evidence establishes a reasonable link between exposure and disease. If that link is established, compensation is warranted. We do not believe, however, that any existing legislative vehicle creates an appropriate or workable scheme for distinguishing legitimate from spurious claims for compensation.

In addition, federally mandated studies—such as those called for under section 301(e) and 104(i) of CERCLA—have either not contributed to our medical understanding of environmental disease or are as yet incomplete. Devising legislation—or a company position—in an emotionally charged atmosphere and without adequate factual underpinnings is fraught with difficulty and peril.

We recognize, however, that Congress has begun consideration of systems to compensate persons who may be harmed by exposure to hazardous substances. Therefore, we believe that several key aspects of victim compensation legislation currently under consideration by the Congress deserve discussion at this time.

First, an observation is necessary regarding whether a Federal administrative compensation scheme should be an exclusive remedy. The legislative proposals now under consideration in Congress would not require that the claimants seeking compensation elect one remedy. We view this as a serious defect. Claimants should be required to make a binding election between litigation and an administrative remedy. Election of an administrative remedy should foreclose further judicial remedies. Otherwise, litigation and its attendant costs to society will surely mushroom.

Second, from industry's point of view, Congress should seriously consider the current problem of inconsistent State laws governing compensation. We live in a complex and litigious society. Business is faced with increasing litigation over exposure to toxic substances both within and outside of the work place. Judicially fashioned remedies are unpredictable and costly. This evolving system holds no prospect of providing in the near future clear guidelines upon which industry can rely and plan its activities. If compensation legislation is enacted, it should provide business with a legitimate degree of certainty in knowing by what rules it will play the game.

Several proposals would create a new Federal cause of action. Instead of creating one more remedy to choose from, Congress should consider a separate preemptive Federal statute to assure consistent and equitable standards for all claimants who elect to litigate. Such standards should be based upon actual causation and not upon unproven assumptions.

Third, if Congress determines that a compensation fund is a desirable part of compensation legislation, subrogation provisions pose difficult issues. Subrogation preserves the fund and penalizes undesirable conduct. However, subrogation also continues litigation and elevates transaction costs that any compensation program should be designed to eliminate.

However, if subrogation rights are eliminated, we firmly believe that the legislative scheme should offer strong incentives to eliminate improper conduct and reward those whose conduct is exemplary. For example, criminal penalties could be imposed on certain types of conduct which result in claims against the fund.

Fourth, the method of funding any Federal administrative compensation scheme deserves careful attention. Several proposals have adopted the CERCLA "feedstock" tax approach to financing administrative compensation. This would be totally inappropriate and grossly inequitable. A tax on petroleum and chemical feedstocks bears no logical relationship to the broad-based problem this legislation is designed to address.

Additionally, such an approach would place the burden of taxation on a few companies rather than on a broader segment of commercial, industrial, governmental and community activities which may involve human exposures to hazardous substances. We urge you not to perpetuate the inequities in the current CERCLA tax system. If Congress decides to establish a program to compensate persons exposed to hazardous substances, we urge you to develop a financing mechanism which taxes all entities who are identified as being significantly involved in activities utilizing hazardous substances, and which taxes all such entities in a manner reasonably commensurate with their proportionate contribution to the total problem. Moreover, such a program must be designed to achieve administrative simplicity.

Atlantic Richfield Co. fully recognizes the difficult challenges before you on these compensation issues. We offer our assistance in developing a technically sound and equitable solution to these issues. We have not touched upon all of the troublesome mechanical and legal problems presented by this type of legislation. We look forward to providing the committee with additional specific views as consideration of this issue progresses both in the Congress and in our company.

I want to thank the members of this committee for giving me the opportunity to present our views today.

[The statement of Mr. Kusch follows:]

STATEMENT OF ALBERT W. KUSCH, VICE PRESIDENT, ATLANTIC RICHFIELD CO.

VICTIM COMPENSATION LEGISLATION

Good morning. My name is Al Kusch. I am Vice President of Atlantic Richfield Company and Senior Vice President for Manufacturing, Research, and Engineering of the ARCO Petroleum Products Company, a division of Atlantic Richfield Company.

My comments today will closely parallel those presented on June 29 of this year before the Subcommittee on Commerce, Transportation and Tourism of the House Energy and Commerce Committee.

I have brought with me today Joan DiNal, Senior Counsel Environmental Affairs and Gary Kovall, Manager of Environmental Legislation and Regulatory Affairs for ARCO Petroleum Products Company to aid me in addressing any questions you may have.

I have been associated with the petroleum industry since 1941, and have been privileged to have been party to the tremendous technical and economical changes to our industry which have taken place during that time. We and other industries are now entering another era of change, of which the subject of today's discussion is a potentially significant part.

Atlantic Richfield Company has for some time had under consideration the issue of compensation for exposures to hazardous substances. We have attempted to develop a corporate position responsive to several key points. However, due to the complexity of this issue, we have not yet reached a conclusion on determining a Company position on all aspects of this issue. Our efforts to date have identified several important considerations with respect to the need for victims compensation legislation. First, we recognize that there is a public perception that environmental exposures to toxic substances present a significant human health risk. Second, as a cardinal principle, we believe that injured persons should be fairly compensated by those responsible for the harm. Third, any legislatively established compensation system must include clear guidelines upon which industry can rely and plan its activities. Fourth, we find that the dimensions of the problem of environmental disease are poorly defined. This leads us to conclude that passage of legislation to compensate persons for non-work place exposures to hazardous substances is premature.

Two recent studies suggest the potentially limited scope of environmental disease. These studies—one by the Office of Technology Assessment and the other reported in the Journal of the National Cancer Institute—estimate that 5 to 7 percent of cancer deaths are related to three factors: occupation, pollution and industrial products. These same reports relate 25 to 40 percent of cancer deaths to tobacco and 10 to 70 percent to dietary habits.

Further, it is difficult to identify causation and to create a compensatory scheme which isolates the cause of disease and allocates responsibility for harm.

There may be instances were toxicological and corroborating epidemiological evidence establishes a reasonable link between exposure and disease. If that link is established, compensation is warranted. We do not believe, however, that any existing legislative vehicle creates an appropriate or workable scheme for distinguishing legitimate from spurious claims for compensation. In addition, federally mandated studies—such as those called for under Section 301(e) and 104(i) of CERCLA—have either not contributed to our medical understanding of environmental disease or are as yet incomplete. Devising legislation—or a Company position—in an emotionally charged atmosphere and without adequate factual underpinnings is fraught with difficulty and peril.

We recognize, however, that Congress has begun consideration of systems to compensate persons who may be harmed by exposure to hazardous substances. Therefore, we believe that several key aspects of victim compensation legislation currently under consideration by the Congress deserve discussion at this time.

First, an observation is necessary regarding whether a federal administrative compensation scheme should be an exclusive remedy. The legislative proposals now under consideration in Congress would not require that the claimants seeking compensation elect one remedy. We view this as a serious defect. Claimants should be required to make a binding election between litigation and an administrative remedy. Election of an administrative remedy should foreclose further judicial remedies. Otherwise, litigation and its attendant costs to society will surely mushroom.

Second, from industry's point of view, Congress should seriously consider the current problem of inconsistent state laws governing compensation. We live in a complex and litigious society. Business is faced with increasing litigation over exposure to toxic substances both within and outside of the work place. Judicially fashioned remedies are unpredictable and costly. This evolving system holds no prospect of providing in the near future clear guidelines upon which industry can rely and plan its activities. If compensation legislation is enacted, it should provide business with a legitimate degree of certainty in knowing by what rules it will play the game.

Several proposals would create a new federal cause of action. Instead of creating one more remedy to choose from, Congress should consider a separate pre-emptive federal statute to assure consistent and equitable standards for all claimants who elect to litigate. Such standards should be based upon actual causation and not upon unproven assumptions.

Third, if Congress determines that a compensation fund is a desirable part of compensation legislation, subrogation provisions pose difficult issues. Subrogation preserves the fund and penalizes undesirable conduct. However, subrogation also continues litigation and elevates transaction cost that any compensation program should be designed to eliminate. However, if subrogation rights are eliminated, we firmly believe that the legislative scheme should offer strong incentives to eliminate improper conduct and reward those whose conduct is exemplary. For example, criminal penalties could be imposed on certain types of conduct which result in claims against the fund.

Fourth, the method of funding any Federal administrative compensation scheme deserves careful attention. Several proposals have adopted the CERCLA "feedstock" tax approach to financing administrative compensation. This would be totally inappropriate and grossly inequitable. A tax on petroleum and chemical feedstocks bears no logical relationship to the broad based problem this legislation is designed to address. Additionally, such an approach would place the burden of taxation on a few companies rather than on a broader segment of commercial, industrial, governmental and community activities which may involve human exposures to hazardous substances. We urge you not to perpetuate the inequities in the current CERCLA tax system. If Congress decides to establish a program to compensate persons exposed to hazardous substances, we urge you to develop a financing mechanism which taxes all entities who are identified as being significantly involved in activities utilizing hazardous substances, and which taxes all such entities in a manner reasonably commensurate with their proportionate contribution to the total problem. Moreover, such a program must be designed to achieve administrative simplicity.

Atlantic Richfield Company full recognizes the difficult challenges before you on these compensation issues. We offer our assistance in developing a technically sound and equitable solution to these issues. We have not touched upon all of the troublesome mechanical and legal problems presented by this type of legislation. We look forward to providing the committee with additional specific views as consideration of this issue progresses both in the Congress and in our Company. I want to thank the members of this committee for giving me the opportunity to present our views today.

Mr. LEVITAS. Thank you very much, Mr. Kusch. Let me start by asking you something that you said in your testimony. Maybe you could provide a little elaboration. You talked about the need for a degree of certainty in the event legislation is enacted on victim compensation, so that there must be clear guidelines, I think you said.

Mr. KUSCH. Yes.

Mr. LEVITAS. And business needs to plan its activities. Could you give me some further understanding of what you have reference to? What is the problem that you foresee, and what is it that you mean by degree of certainty in this area?

Mr. KUSCH. May I defer to my legal arm over here?

Mr. LEVITAS. Sure.

Mr. KOVALL. Mr. Chairman, what we are referring to really is specifically the two-tiered type of approach that was recommended in the CERCLA 301(e) study. The fact that because there is no election of remedies, and because there is no specific type of Federal statute for the cause of action specified in that report, that we are concerned that we are going to see a rather dramatic evolution of tort law. Hand in hand with any compensation scheme, this evolution begins to break down traditional rules of causation which we think any compensation scheme ultimately is going to have to do.

And we are concerned that that—we are sort of faced with that situation today. The courts have been very creative in this country in fashioning new remedies for plaintiffs in so-called toxic tort litigation. I think we are right at the very beginning stages of that evolution. We are concerned if Congress tackles this issue and does not tackle the issue of specific liability rules, limitation, reasonable and ensurable defenses so we can predict our conduct and ensure our conduct, that we are going to lose total control of any type of compensation. It will end up being another black lung type of program. We are very concerned about that.

Mr. **Levitas**. Both of you advocated a waste-end based tax to fund Superfund in general; and if not in general, certainly then in any additional areas that would be added on. Obviously there is some secondary benefit from a waste-end tax in that it would encourage recycling and other types of methods as alternatives to land disposal.

But we have heard some concerns about a waste-end based tax approach, particularly in terms of its regulatory and cost implications, both to the Government and to industry. I wonder if both of you would let me have your thoughts on that aspect of it, recognizing, as I have already said, that there is certainly incentive built into a waste-end tax to achieve another purpose, which is to reduce reliance on land disposal.

And there is also, I think both of you indicated, a fairness issue that would be addressed by the waste-end tax. But what about the regulatory and cost implications?

Mr. **Browning**. Worth noting I guess that I met Mr. Kusch this morning, so I had no idea of which side of that issue he might come down on. The fairness issue aside, and I think that is fairly evident to everyone, the discipline placed today on waste disposers by the feedstock tax is nonexistent. Once we pay the tax we do what we can, and when times are good we are successful; when they are not so good, we are not, to pass that tax on to the ultimate consumer.

It serves as no discipline on those of our customers and the public who ultimately dispose of the vast majority of the materials that we produce and sell. The question of the waste-end tax was addressed at the time of the enactment of the original Superfund as I recall it. And at that time the—well, the overriding argument was that it would be impractical to collect.

I would suggest today that with the experience we have had with RCRA and the manifests that are available which do track hazardous waste, that particular objection is no longer quite as telling as it might have been. And I am also reminded that beginning I think it was October 1 or thereabouts, people who do dispose of materials in the ground are required to pay, I think it is a closure fee. So the recordkeeping system is much more with us today. And I think that we might be able to do this now without some of the problems that certainly were real when we began to do this 2 years ago.

Mr. **Levitas**. Would you like to add to that, Mr. Kusch?

Mr. **Kusch**. Mr. Kovall.

Mr. **Kovall**. Mr. Chairman, in your letter to Mr. Kusch you asked about whether or not we have been able to develop a corporate position; and if not, why not. I think it is pretty clear we don't have one—a full position yet. But if not, you asked what were some of the troublesome points. Certainly, I think you have hit right upon one of the real keys. We have perhaps an unusual corporation in that we have, we are not just a petroleum or chemical company operation, but we have solar, we are into solar engineering and mining coal and nonferrous metals. And the impact of any revenue-raising device is being very heatedly debated within our corporation.

It is no secret that we have been a strong proponent for switching to waste-end tax for purposes of CERCLA authorization. That comes primarily from what we think has been a positive experience in the State of California which has enacted a Superfund law with a multitiered waste tax revenue-raising device. And for some years it has had a waste fee process for funding its administrative programs in California.

We recognize, however, that a waste tax provides perhaps only a window of financial revenue flow, because if the tax in fact accomplishes what you would want it to accomplish, which is to reduce the wastes for disposition, the wastes do in fact become reduced. If in fact the tax is too high, I am sure you can imagine a scenario that one might be more encouraged to violate the law and not report the waste. In the State of California there has been, grossly speaking, a 30- to 40-percent reduction in wastes reported for disposition and subject to the tax in the last 2 years since the tax came into place.

So we are looking at the role that a waste tax should play in a total revenue picture. I think we would want to leave this message with you and this subcommittee very clearly, though, that we are very much opposed to the feedstock tax which we are convinced is inequitable. A recent Fortune magazine article indicated that 50 percent of that tax falls on five U.S. companies. Two of them are sitting here at this table today. We don't think a feedstock tax provides any appropriate environmental incentives, and it is terribly, terribly cumbersome as the newly proposed Internal Revenue Service regulations could demonstrate.

So we are looking at a wide variety of funding mechanism ideas. We really hope in the very near future that we will come out in the open concerning those ideas as we have about our basic advocacy. But we think a waste tax can play some role in at least CERCLA reauthorization for some period of time.

Mr. LEVITAS. I think you have addressed some of the concerns that we have in your comments. We would appreciate it if you would share with us any further conclusions you come to as your company goes through these considerations.

Mr. KUSCH. We will as we get to them.

Mr. LEVITAS. I would appreciate that. What we are looking at is not only an extension of Superfund, but I think that there is certainly overwhelming consensus, if not unanimity, that we are not only going to have to extend Superfund, but we are going to have to expand it. Instead of $1.6 billion we are looking at many billions more. And I think maybe I am understating that. We want to devise a system which is fair and which equitably shares the historic social cost that is a result of what we now know that we didn't know. At the same time, we want to provide for the future adequate resources and appropriate incentives to avoid perpetuation of problems of the past now that we do know what they are. Accordingly, I would look forward to receiving anything that you might have on that.

Mr. KUSCH. Yes.

Mr. LEVITAS. Let me move to another point. Both of you addressed the possible changes in the compensation system. However, I don't recall that either of you addressed the question of shifting burden of proof, which has been discussed by a number of witnesses before this committee, as being a minimum change that would be required if we or even if we don't go to a new administrative remedy. The difficulty remains in establishing the causal relationship and the fact is that most of the information probably lies, in this instance, with the defendant, rather than the plaintiff. The only way that we can have any sense of justice in the existing court system would be to shift in some way the burden of proof once certain threshold criteria were met.

Now, I would like to get your thoughts on that. I think, Mr. Kusch, you mentioned it. In the discussion, on page 4 of your testimony, you talked about this. However, I am just curious as to how you feel about shifting burdens of proof.

Ms. DINAL. One of the problems of shifting the burden of proof is that you have to have some criteria for doing so. I think, as was indicated by the previous panel, the problem is that there is just no certainty out there. The studies, the epidemiological and toxicological studies that have been done, have been inconsistent, and/or inconclusive. You can talk about shifting the burden but there has to be some threshold for doing so. And without some agreement on the part of the scientific community as to what might be a trigger exposure, it is very difficult to establish an appropriate threshold.

Another problem is when you are talking about a cancer I think the prevailing view among scientists is that the cause of such cancer is multifactorial. And so what we are talking about is a person being exposed to a number of triggers throughout his or her lifetime. In traditional causation you are looking for a "but for." You don't find that, perhaps, in the situation of cancer.

As we have seen with asbestos exposures, if you smoke and you are exposed to asbestos, your likelihood of developing certain types of asbestos injury are enormous as compared to someone who is exposed to asbestos and doesn't smoke. I think that when you talk about shifting the burden and we hear about uncertain evidence from the medical and scientific community over lifestyle factors, diet, etc. we just don't know what the triggers for disease are. And until we get some better guidance from the medical and scientific community, it is hard for lawyers to decide where the threshold should be for shifting that burden. If you shift the burden immediately to the defendant he has to prove a negative which is impossible.

Mr. LEVITAS. Let me pursue that just for a minute and then I will yield to Mrs. Johnson. This is obviously a very difficult situation. It is even slightly more vague than the whole discussion we have had for years about acid rain, when everybody was telling us, as you know, that we don't have enough proof. Yet, the fish are still dying in the lakes. Now, we are beginning to think we maybe do have some proof. I think that with or without that recent report, you would have seen legislation coming forward.

Certainly people in the Northeast—Connecticut, Massachusetts, Minnesota, Wisconsin—places like that, have a feeling about this. And there is, I think, if nothing else, a rather widespread and growing perception that there is a relationship between toxic chemicals and cancer or other illnesses. Associated with that, a like relationship between hazardous waste, dumps and the same type of problems.

Now obviously there is litigation going on right now. We heard from lawyers a few months ago who were telling us about the cases that are coming. They are increasing. There is a whole new segment in the bar handling toxic tort cases. Obviously there is somebody who is proving something to the satisfaction of the juries and the courts that are hearing them.

One of the questions and one of the paradoxes that we are confronted with from time to time was again raised yesterday by Assistant Attorney General McGrath. He says one of the ways you go about establishing causation is that you look at what the expected or normal rate of illness or disease, cancer deaths, is in a particular situation.

You then introduce the factor of the hazardous waste site or the nuclear fallout or whatever it is. And you show an increase of 5, 10, 15, whatever the percentage is. Now, you have your plaintiff come in and say, oh, there is a relationship here. But how do you know whether that plaintiff falls within the 15 percent or whether it is part of the first 100 percent?

As I said to Mr. McGrath yesterday, that is a very nice lawyer's problem that we can play around with either in a law school class on torts or in a philosophy class on some other part of the campus. However, I don't think it is going to go very far either with juries or Congress. Once you find that situation where there is obviously something going on that is out of the ordinary, I think the response is that we have got to provide compensation for whoever it is that might have fallen within that category, even if it is overly inclusive.

Now, my question is how do you respond to the issue of causation, recognizing the fact that there is litigation going on? And you might from your perspective, Ms. DiNal, share with us, what is the experience at Arco? Do you have a lot of claims from people who claim injuries? Do you have any ongoing cases?

Ms. DiNal. No; we don't have a lot of claims. I do think that the causation requirements probably would have to be relaxed if we are talking about a tier 1 compensation-type scheme. I think that is going to be one of the tradeoffs in tier one, that there is going to be a lesser burden for those people. But, at the same time, their damages are going to have to be limited in some way to medical expenses, and some lost income. They will have to forego the types of damages they would be able to ask for in litigation such as pain and suffering and emotional distress. I think that there probably will have to be a mechanism set up so that the information about particular substances is pulled together by the appropriate agencies, and so that there is some presumption created if a person can show a certain exposure over a certain length of time to a certain substance which is known to increase the likelihood of developing cancer.

I think it can be done in a compensation-type scheme. It is probably similar to, something, like workers' compensation. In exchange for the worker being able to sue for everything, if he is injured in the work place and can prove negligence he receives all his medical expenses and a disability income if necessary on a no-fault basis. I think we are talking about that kind of a tradeoff.

Mr. LEVITAS. I am curious if either company could just give us an indication. You are two large companies. Are you getting a lot of litigation on this? Do you have 10 cases, 50?

Mr. KUSCH. I think we have on the order of 50, isn't it, Joan?

Ms. DINAL. Over waste sites we have really just one.

Mr. LEVITAS. Waste sites, one.

What about chemical exposure in general?

Mr. BROWNING. We have—I am not aware of any cases that we have involving waste site exposure. I am not aware of any pending litigation that is prolonged in the workmen's comp area. We have a number of product liability cases, our materials in somebody else's workplace. They don't sue the employer, they sue us. There are a few of those.

Ms. DINAL. Yes; we have maybe about 50 some odd of those.

Mr. BROWNING. Yes.

Ms. DINAL. And about 20 asbestos cases, I think.

Mr. BROWNING. Mr. Chairman——

Ms. DINAL. The bulk of the asbestos cases have come in, of course, since the chapter 11's.

Mr. LEVITAS. Mr. Browning.

Mr. BROWNING. On the previous question, I don't have an answer for you, but some observations which might give you some lines of thinking that would be helpful that we have been pursuing.

In the first place, it has been implicit in your questions I think and in the observations here that we do make a distinction between acute illness and the chronic illness. The burn, the nausea, the dizziness. Those things fit into the traditional workmen's compensation or tort litigation without too much difficulty. Normally the sums involved are not great. The relationship between the event and the cause, the manifestation of disease, is fairly easy to prove. So those cases seem to be handled reasonably well.

The chronic case, the multiple employer, the long, latency period, those are the things that create the difficulties, where the emergencies are greater, and in this case you would be thinking of a large number of litigants; there appears to be an opportunity to get resources necessary to get the scientific proof to begin to establish causation.

I think the case we really need to focus on in the kind of system which you are considering here is where we have few claimants relatively in any given instance, and the case just doesn't permit the expenditure of the sums of money necessary to carry forward the purpose.

We have looked, and I don't have this system fully evolved in my own mind yet, but we have looked at the use of science panels, people who are expert in the disease processes, who could help establish a relationship, a causal relationship between a particular exposure and a particular disease process.

In my remarks here I mentioned a variation of this which I have personally found intriguing. And that has to do with a court-called expert, perhaps someone who is qualified to expound on the views that have been educed from studies by the National Academy of Science or some group like that.

Now, unfortunately, if that system is in place you will find that in most cases they will tell you that with lung cancer and this exposure you are dealing with a 15 to 25 percent increase in the disease process you are talking about. And that is compounded with smoking, and a few other things, as you certainly would be aware of.

I can only say in situations like that, where the causal relationship is so tenuous, or is tenuous to some extent, and you are going through the outside expert in an administrative system, the amount of the award might have to take into account that there is a likelihood that this person did not get that disease from that particular exposure.

It is some of the give and take that we have gone through in the regular Workmen's Compensation System where we are dealing traditionally with the finger in the drill press, the more acute emergency. Just observations which we are working on.

Mr. LEVITAS. Thank you.

Mrs. Johnson.

Mrs. JOHNSON. I would like to continue with the subject that we are discussing, the issue of an independent expert witness. How does that differ from toxic substance documents? Or do you think there is any advantage? What are the pros and cons of panels of independent witnesses and documents?

Mr. BROWNING. Well, yes. I do see some differences. In the first place, let me say to you that this idea of the court-appointed expert has been around for some time. My recent interest in it was stimulated by Mr. Robert Bernard who presented a paper on it a couple of weeks ago at one of the meetings here in Washington. If you are going to work in the tort system, it seems to me that you cannot deny constitutionally the parties the right to bring in their own expert witnesses.

I am not sure how you might introduce a paper, which just evolved from a National Academy of Science or some similar body, into the court of law. Certainly a witness who is basing his testimony on that would be in a position to bring it into play. And you would have to permit cross-examination of the expert, I believe, to satisfy the requirements of the court.

So a document which cannot be explained and updated and defended doesn't seem to me to be too useful in a court of law. In an administrative process, you might legislate in a way which would make that a more likely event. But even there I think both parties would need to have some access to either the author of the document or to the—someone who would defend the reasoning behind it, and also to make sure that the document was up to date.

Now, this is a field, most of these things we are learning about, you know. Not as much as we would like, and certainly not as quick as we would like. But it does—we are learning more every day. And we need to have that most recent expert testimony.

Mr. **Kovall**. I agree with Mr. Browning. I want to steer away from using the term technical substance document because it is a term that is being used in a couple of pieces of legislation in this Congress. But that concept I think has some value in an administrative proceeding, and I am assuming those types of documents which go to the causation in question are going to be subjected to rather rigorous regulatory proceedings and they are not going to just be a creation of some individual scientist's imagination—that these documents will go through some sort of review and be used for the administrative proceeding, where I visualize that of necessity you are dealing with a different type of causation showing than you are in the courts.

I think there is a tremendous danger—and I think it has been testified to perhaps before this subcommittee by Mr. Horowitz of OMB—that there is a tremendous danger of not making it very clear that if you are going to relax causation, don't carry that over to the litigation sense because you do run into the constitutional problems. And it is fundamentally disruptive of the judicial proceeding.

Mrs. **Johnson**. Do you think causation should be relaxed only if other remedies are foregone? If there is a selection made?

Mr. **Kovall**. Yes; we have stated that there ought to be a very clear binding election of remedies, and if you go one route, that is the route you go. You go to court with perhaps tougher standards, more clear——

Mrs. **Johnson**. If you establish the system with a binding election of remedy, then you would not object to some loosening of the causation standards?

Mr. **Kovall**. That is true.

Mrs. **Johnson**. Then in the area of subrogation, what would be your reaction to limited subrogation that dealt only with those situations where there had clearly been deliberate and willful misconduct?

Mr. **Kusch**. I don't think we are prepared to speak to that question. We are having quite a debate right within our own corporation on this. It has anything but come to a conclusion.

Mrs. **Johnson**. OK.

Mr. **Kusch**. I would guess that the debates that are going on on a number of these issues right within our corporation, among the various entities, companies, if you would, that there are probably parallels in all the debates that are going on before committees like yours, and in many other places.

Mr. **Browning**. My company doesn't have a position on that, but I will give you a personal observation.

The question of subrogation is a very difficult one. And, of course, the idea initially is to get a system which eliminates, to the extent one can, the transaction costs involved in getting money to the injured party. Subrogation would seem not to go in that direction, if you are just going to move the litigation off to another arena at another time.

Although if carefully defined, the kind of exception that you have raised would seem to me to be worth serious consideration.

Willful misconduct should be punished, and the system ought to be designed so that it militates against those people who have gone beyond the ordinary care——

Mrs. JOHNSON. Would you just clarify for me because this came up in yesterday's hearing as well as today's hearing. Could you just clarify for me what kinds of cases are being already taken care of through existing systems? Which kinds of cases are addressed through which systems?

Mr. BROWNING. You mean which cases are being taken care of today in the court system?

Mrs. JOHNSON. For instance, your testimony says, Mr. Browning, the present tort system will probably continue for some time to be a principal means. Are there other systems besides the tort system that is taking care of or addressing some aspect of it? And what aspects is the tort system handling?

Mr. BROWNING. Well, to get to the second part first, there has recently been an announcement I understand, somewhat premature but not too much, of the settlement of the claims of the people who lived around Love Canal. Certainly a few months ago there was some evidence, or a settlement of the claims of those who had been injured, I believe it was in Louisiana as a result of some environmental episode there that occurred several years ago.

So, again, you have large numbers of claimants, and you have a situation where the tort system is working. Presumably to the not total dissatisfaction of both sides, although I am sure that the people paying think they paid too much, and the people who are getting paid don't think they are getting enough. But that is the system.

Mrs. JOHNSON. Wouldn't you say that was primarily a negotiated settlement, or was that a court settlement?

Mr. BROWNING. It was litigation, yes, in both instances as I recall it.

Ms. DINAL. Yes.

Mr. BROWNING. Certainly in Love Canal, lots of suits were filed. And I am told that while the announcement is premature, that they are close to some kind of an accommodation there. So the tort system does work in some cases. When you get away from the tort system and you deal with the administrative system, the only one that comes to my mind quickly is the Workmen's Compensation System. And it is used to take care of a good many of these so-called toxic torts.

I don't know of a single system that is operable in environmental problems.

Mrs. JOHNSON. Do you have any idea how many of the workmen's comp cases are related to this kind of a cause? Do you have any idea how much is being——

Mr. BROWNING. In our case, it is certainly a very small fraction. We don't have many claims.

Mrs. JOHNSON. Ms. DiNal?

Ms. DINAL. No; that is the same situation at ARCO. In relation to all the workmen's comp claims, very few of them are for some kind of hazardous substance exposure.

Mr. KUSCH. As a matter of fact, they are rare.

Ms. DiNal. Yes, and most of them are for skin irritations or burns.

Mrs. Johnson. Thank you, Mr. Chairman.

Mr. Levitas. Thank you.

Mr. Browning, I understand that you are chairman of the Chemical Manufacturers Association's Strategic Options Group, which has examined policy alternatives on victims compensation.

Mr. Browning. I was, the committee is in a state of limbo at the moment.

Mr. Levitas. That was my question. My question is that I wanted to know how that group is coming along with its deliberations.

Mr. Browning. I think this is true, Mr. Chairman. The board of directors of CMA met yesterday. And our original charter was to explore many of the issues and sort of define the issues that needed further elaboration, and we made that report. The board of directors, I am told, agreed yesterday to reconstitute the committee, and it isn't clear or isn't certain at this point that I will be the chairman, although there has been that indication.

Mr. Levitas. What do you see as the direction? Obviously you can't anticipate what is going to happen, but what sort of strategic options are you viewing other than those which we have all been hearing about from the 301(e) study group?

Mr. Browning. This is largely the sort of thing we would review. The merits of the various proposals and the interrelationship of these things. Now I think Congresswoman Johnson raised the point, if you go for a lessening of the burden of proof, does that push you toward an administrative system that is exclusive?

These are the kinds of tradeoffs that I think ultimately we are going to have to weigh and decide, and how much do you lessen the burden of proof in that situation?

Mr. Levitas. I think that there are obvious differences of opinion, but I also think that to the extent you reduce the burden of proof, you go for some tradeoffs which may be a limitation on liability.

Mr. Browning. Yes.

Mr. Levitas. On the other hand, the problems, without getting into all of them, are so many as you go down the line. For example, you have a compensation system, and presumably you are being compensated for an ailment which you now elect exclusively to receive from an administrative tribunal.

A year later, instead of having an ailment here, you now have an ailment there. Have you elected exclusively to deny compensation for that ailment? If that ailment is one which is more precisely related to a particular type of chemical to which there was exposure, you think well maybe I won't go into the administrative tribunal for that ailment. I will go into court because I have got a better case here.

I am not suggesting any answers. I am simply saying, looking at it even superficially, the problems begin to unfold almost in front of your eyes.

Mr. Browning. The only quick answer that comes is you have a time limit. If you have taken a bite of the apple today, you don't get another shot at it for three or four years, something of that sort. But it is a difficult problem.

Mr. LEVITAS. I am just curious as to the direction in which CMA's strategic options group was headed, and I think you have answered that question.

Mr. BROWNING. I think one of the things we would be doing certainly is working more closely with the insurance people to see if we can make sure that we are in an insurable area with the claims that might arise. And explore—I think we need to get into more details on the workings and adequacy of the compensation being provided by the Workmen's Compensation Systems for these chronic injuries. We have both given some general thoughts. But that needs a further review.

Mr. LEVITAS. Mrs. Johnson.

Mrs. JOHNSON. Just sort of along the same line, in your estimation, being as familiar as you are with the complexities and the needs, do you think if left to its own evolutionary trends that the tort system would be able ultimately to deal with the problem? Leave it up to judicial interpretation?

Mr. BROWNING. I guess if I answer the question on the basis of my knowledge today of the number of claimants and those that I perceive to be uncompensated, I would have to say that the answer is yes, with the exception of small claims.

Now, I think there probably are some people who couldn't go for the million dollars or so. But they do have some difficulties. Perhaps there is an area there that needs to be thought through more carefully. But our experience and what I read doesn't tell me that there are a great number of people uncompensated as a result of exposure to hazardous materials, particularly around dump sites.

Mrs. JOHNSON. Thank you.

Mr. KUSCH. The problem that you as legislators are facing is the tremendous public perception that they are really being harmed. And I would guess that back in various districts who are represented in the Congress are people like you folks who run into a lot of that when you go back home. There is no way, even if you get all the evidence and science in the world, you can tell those guys, you know, nothing is happening to you. There is no way you are going to get away with that.

So then you are faced with, well, what kind of legislation do I create to mollify that sort of thing? It is a very difficult, difficult problem.

Mrs. JOHNSON. Yes.

Mr. LEVITAS. Yes; I just would make a comment about that, because you are absolutely correct, and I take what you say as being a substantive statement.

Mr. KUSCH. It is my own opinion. It is not——

Mr. LEVITAS. I take it as a substantive statement.

Mr. KUSCH. All right.

Mr. LEVITAS. But I will tell you that in the minds of some people that gets translated into the fact that Congress is simply reacting to witches and goblins and making a political response. However, it is my sense, and I am not running down science in this regard, that there is some sort of commonsense understanding that people have. It is like, and I don't know if this is an appropriate analogy, but it is like pornography. It is hard to describe, but everybody knows what it is when they see it.

It may be hard to establish to the satisfaction of scientists and certainly it is incapable of being defined satisfactorily to statisticians and epidemiologists. But there is sort of a correct understanding by people that say, look, there are more people getting sick right here near that toxic waste site than there are everyplace else. So there must be something wrong there.

Mr. KUSCH. Yes.

Mr. LEVITAS. So I take what you say as a substantive observation. If I could predict, I would predict that Congress is going to respond in some way as a result of that.

Mr. KUSCH. I think you have no choice.

Mr. LEVITAS. I think that is right. I am sorry.

Mrs. JOHNSON. You just pursue that.

Mr. LEVITAS. The last question I have is something which I think, Mr. Kovall, or Mr. Kusch alluded to and which we asked at our earlier set of hearings. You, talking about the need for certainty, said in order to make your plans, above all you had to be able to have an insurable system.

When we were talking with the representatives of the insurance industry, I remember asking the question, how do you actuarially provide for insured coverage for this type of situation when there is no experience? I mean, there really is no experience at this point, at least adequate experience, to define what should be the premium costs associated with this type of risk.

I wonder if any of you at the table had any thoughts on that subject because obviously it will take a period of time of insurance coverage and experience in order to find out what we really are talking about regardless of what system is put in place.

Mr. BROWNING. It is really the thought that I had in mind when I was talking about the direction of the CMA in the future. I think we do have to work with the insurance industry to begin to define the boundaries. If the burden of proof is relaxed this much, what does that do to the risk that we are running that you would have to insure? We don't have good understandings of that.

Now, everybody understands preponderance of evidence. We have lived with it a long time and actuarially you can predict that. If we begin to play with that, it is a whole new ball game. But we would have to call on their experience in other arenas and to help us put some price tags on it.

Mr. LEVITAS. I have no further questions.

Mrs. JOHNSON. I don't have any further questions. Thank you.

Mr. LEVITAS I want to thank each of you for your willingness to participate in our review of the victims' compensation issue and also my thanks to the other witnesses who appeared before the subcommittee during the six days of hearings we have held so far on the subject. Your contributions have been invaluable and have provided us with a record that will enable us to go forward with our tasks and measurably assist us in more knowledgeably addressing the issue of hazardous waste and victim compensation.

I think the more we hear, the more obvious it becomes that the issue is complex. There are differences of opinion. There are areas of uncertainty that will not be easily resolved, if ever resolved. In view of this, it would be premature to attempt any conclusions.

But we are going to be analyzing this extensive record over the next weeks and months ahead with the intent of providing some specific legislative proposals or other proposals on this subject in order that we can ensure that we will provide all those who wish to comment an opportunity to do so.

Accordingly, I will, without objection, order that the record of these hearings be held open for two weeks. Specifically I might say with respect to your comment concerning the 3M Corp., we will certainly be more than happy to accept their filing for that purpose.

Mrs. JOHNSON. Thank you.

Mr. LEVITAS. With that, again, thank you for your participation. I appreciate your being here.

The subcommittee stands adjourned.

[Whereupon, at 3:02 p.m., the subcommittee was adjourned, subject to the call of the Chair.]

AUG 25 1983
OFFICE OF
POLICY AND RESOURCE MANAGEMENT

AUG 23 1983

Honorable Elliott H. Levitas
Subcommittee on Oversight and
Investigations
Committee on Public Works and
Transportation
House of Representatives
Washington, D. C. 20515

Dear Congressman Levitas:

Thank you for your letter of August 4, 1983, concerning EPA's risk assessment and risk management policies. We have begun to collect the information you requested and will provide you with as much information as possible by September 9. In the meantime, I would like to indicate how we intend to proceed and perhaps provide some preliminary answers to your questions.

Your first question concerned EPA policies for risk assessment and risk management prior to Mrs. Burford's tenure as Administrator. It is my understanding that during this period generic policies and uniform guidance on risk assessment were not articulated by the Agency in a formal way. We are searching the record, but it is likely that policy in this area will have to be inferred from an analysis of individual cases.

Second, you ask if there were any changes in these policies during Mrs. Burford's tenure as Administrator. Again, I believe that risk assessment and risk management policies at that time were not explicitly stated and will have to be inferred from an analysis of individual cases. A memorandum from Dr. John Hernandez was specifically referenced in your letter. We have asked each program office to review and comment on this memorandum and submit to us any comments generated at the time the memorandum was issued.

Finally, you asked whether there had been any changes in these policies since Mr. Ruckelshaus became Administrator or if any are being contemplated. The Administrator is at present engaged in several efforts that we hope will result in a careful articulation of policies in the areas of risk assessment and risk management. The impetus for this activity is the broad public concern that surrounds policies for dealing with environmental risks. Some of the issues are scientific--how hazards should be identified and assessed. Others are managerial--ensuring that we reduce total risks in the most efficient possible way, which suggests, among other things, coordination of total efforts across media and hazards. Still others are primarily philosophical--including the extent to which risk reduction should be balanced with other important goals.

The Administrator has initiated discussions with the heads of other Federal agencies and departments involved with risk assessment and risk management. The goal is to achieve greater cooperation among the relevant agencies, to improve the use of scientific knowledge in regulatory decisions, and to seek to reduce overlaps, gaps, and inconsistencies in the way agencies handle related regulatory issues. At EPA, we are assembling the analytic basis to help with that reexamination. We have set up a Task Force charged with:

- Finding out where we stand on uniform risk assessment guidelines for EPA and developing a plan and schedule for updating and writing these as needed;
- Developing policies for the management of significant health risks, and assuring that risk management information on such factors as exposure, hazard, uncertainty, risk reduction, inter-media transfer and cost are presented to Agency management in a consistent, comparable format;
- Improving our ability to respond quickly and efficiently to problems of immediate national concern--dioxin contamination, for example; and
- Improving coordination between EPA and other Federal agencies responsible for controlling toxic substances.

The final report to the Task Force, due November 30, will be an important input to an ongoing process of developing coherent and consistent strategies for risk assessment and risk management. We will provide you and your committee by September 9, however, some tentative answers to your third question. We also shall keep you apprised, of course, as this process develops.

I will be happy to meet with you at your convenience to discuss these issues and the progress we are making in developing policies for risk assessment and risk management.

Sincerely,

Milton Russell

Dear Congressman Levitas:

This letter and the enclosed materials are submitted in response to the questions raised in your letter of August 4, 1983. The program offices have provided a variety of materials that I hope will be of interest to you. Let me summarize the highlights and elaborate on my original response to you of August 23.

Risk assessment and risk management prior to Mrs. Burford's tenure as Administrator

The recent National Academy of Sciences report on risk assessment and risk management has done much to clarify some difficult topics. It has been especially useful in clarifying the distinction between the two concepts, and in encouraging staff and managers at all levels to make it as clean as possible. Simply put, assessment is a description of risk, management is a judgment on what to do about it.

Risk assessment interprets toxicological and other data on the hazards of pollutants, usually relying heavily on animal experiments, and arrives at conclusions on that pollutant's human health effects. This is then combined with data on the patterns and extent of human exposure from a particular pollution source or set of sources. The result is a calculation (for carcinogens this is generally expressed as a probable upper bound) of the health risk of a pollutant. In contrast, risk management is the process of weighing the results of the risk assessment, along with economic and other important factors, and arriving at a decision on actual control of the target source(s). The NAS report stressed the importance of keeping the assessment component entirely free of judgments that anticipate desirable degrees of control. All such evaluations should remain in the domain of risk management.

This distinction was less obvious three years ago, and, as I stated to you in my letter, risk policies prior to Mrs. Burford were not explicitly stated as such, and are best interpreted from the actual decisions made. On the other hand, certain procedures, especially those affecting what we now regard as the purely scientific and technical process of risk assessment, had by that time been made formal, at least in draft form. Copies of the pertinent documents are enclosed.

The Interim Cancer Assessment Procedures (1976) and the proposed Guidelines for Mutagenicity Risk Assessments (1980) were issued prior to the tenure of Mrs. Burford. They represented the state of a new science as it was then. They were not altered under her administration, but are now being reviewed to incorporate new topics and update old ones.

The major questions on risk assessment, both prior to Mrs. Burford and during her administration, relate more to how consistently the available guidelines were applied than to any conflict between competing scientific approaches. Imperfect as risk assessment was then and is now, there is no credible scientific alternative to the basic approach embodied in the existing draft guidelines.*

The major controversies since the publication of risk assessment guidelines have centered instead on issues of risk management. The major questions are:

> What weight should be given to the results (and especially the uncertainties) of both qualitative and quantitative components of risk assessments?
>
> To what degree are formal policies on the management of risk possible or desirable (especially in relation to the requirements of statutes)?

---

* There was discussion and consideration of distinguishing among carcinogens with differing modes of biological action, including some that might have exposure thresholds below which no risk is present. I enclose a copy of a report prepared and circulated by the Carcinogen Assessment Group on this subject, along with the peer review commentary it evoked. It was decided that the available scientific evidence did not yet support the use of such an approach. Dr. Hernandez testified to this effect shortly before he left the agency.

The first attempt to deal formally with these questions prior to Mrs. Burford's administration resulted in the enclosed draft Cancer Policy Statement, produced by a subgroup of the then-active Toxics Substances Priorities Committee (TSPC). In addition to the general questions above, the statement dealt with the following specific types of judgments:

> At what level of risk to the population or to individuals should the agency act?
>
> What should be target levels for regulatory control?

The group itself was unable to reach full consensus (see enclosed memorandum from Dr. Arnold M. Kuzmack and Dr. Elizabeth L. Anderson to the TSPC). Though the work was begun under the previous administration, it was completed during the Burford administration. Mrs. Burford and Dr. Hernandez commissioned no further work in this area, and did not formally implement the draft cancer policy in this or any other form.

Risk assessment and risk management during Mrs. Burford's tenure

As stated above, there was no change in the content or use of risk assessment guidelines during the Burford administration. Differences of opinion did, however, exist in relation to risk management.

The memorandum from Dr. Hernandez which you forwarded to us for comment is the only instance we have come across where an attempt was made to create a formal alternative to the risk management policies suggested by the TSPC. We have reviewed the headquarters files and are unable to find any written commentary in response to Dr. Hernandez on his memorandum. The only possible reference forwarded to us by the program offices is a memorandum to the Deputy Administrator from Marilyn Bracken; I do not think it is relevent to the question you raise, but have included it for your review.

Dr. Hernandez's memorandum is aimed at the evaluation of local incidents (I believe it was written with the Dallas lead case in mind), rather than at regulatory policy in general. We believe it reflects Mrs. Burford's and Dr. Hernandez's emphasis on the need to have quality assured data and peer reviewed studies prior to taking any action on potential environmental problems, and to review every decision on a case by case basis.

This philosophy was also applied to broader regulatory action under Mrs. Burford. Case by case review does not lend itself to extensive or formal policy statements, and to our knowledge none was ever written. Some decisions on individual regulations made under Mrs. Burford, however, do appear to depart from the draft TSPC Cancer Policy.*

Current efforts on risk assessment and risk management

Since Mr. Ruckelshaus took office there has been a strong emphasis on clarifying, improving, extending, and utilizing uniform risk assessment procedures. There is equal interest in the development and implementation of better risk management policy.

The vehicle for this work is the Task Force on Toxics Integration set up by Deputy Administrator Alm, whose basic activities I described in my first letter. Richard D. Morgenstern, Director for the Office of Policy Analysis within the Office of Policy and Resources Management, leads this group. Membership includes Dr. Anderson and Dr. Kuzmack (who had prime responsibility, respectively, for risk assessment guidelines and the draft cancer policy). The task force also includes senior representatives from the regional offices and each of the Assistant Administrators.

---

* I have included an article from a recent issue of "Science," which quotes a memo written by Burford to the White House referring to cancer policy as "a policy this Administration is changing." The Burford memo anticipates controversy over a decision on the pesticide permethrin -- controversy that never in fact materialized, to our knowledge. As part of our Toxic Integration Task Force (see next page) we have in fact reviewed the risk management aspects of the permethrin decision, and found nothing unusual (see enclosed report, referenced next page). The important conclusion here is that Mrs. Burford was aware of case-by-case departures being made from previous policy, and anticipated that it would generate controversy.

I enclose copies of the pertinent reports the task force has produced to date. Of particular interest is the report of the subcommittee on risk management, which analyzes 27 recent regulatory actions for their positions on risk management. The report displays, for each action:

- The name of the regulation, standard, or guideline;
- The pertinent route of human exposure to risk;
- The source of exposure to be controlled;
- The population whose risk was considered as part of the regulatory decision;
- The health effect of principal concern;
- The strength of evidence of risk presented to the decision maker;
- Estimated levels of pre- and post-regulatory risk;
- Any treatment by the regulatory analysis of intermedia transfer of pollution (air to water, water to solid waste, etc.);
- The regulatory alternatives considered;
- The results of any cost-effectiveness analysis performed; and
- Considerations on which the decision was finally made.

The analysis has revealed wide variations in the way different programs treat these factors. Much of the variation is attributable to the statutes under which the actions are taken. However, the Administrator is anxious that:

1. Unnecessary inconsistencies in the control of risks are minimized or eliminated;

2. That analytic presentations on risks and other factors affecting the decision are clear and complete; and

3. That his discretionary powers (a) reflect consistent policy and (b) are exercised with full awareness of the impacts of previous regulations affecting the same chemicals and industries.

The issues here are difficult, and I do not want to convey the impression that we have reached any final conclusions or are about to make major changes in current policies. We do think, however, that this work is on the right track, and will produce substantial benefits in helping us to make clearer and more consistent decisions.

I am grateful for your interest, and hope that you will follow our work as it progresses. I hope the enclosed materials are useful, and will be glad to be of additional assistance if you need more.

Sincerely,

Milton Russell

Enclosure

This philosophy was also applied to broader regulatory action under Mrs. Burford. Case by case review does not lend itself to extensive or formal policy statements, and to our knowledge none was ever written.*

Current efforts on risk assessment and risk management

Since Mr. Ruckelshaus took office there has been a strong emphasis on clarifying, improving, extending, and utilizing uniform risk assessment procedures. There is equal interest in the development and implementation of better risk management policy.

The vehicle for this work is the Task Force on Toxics Integration set up by Deputy Administrator Alm, whose basic activities I described in my first letter. Richard D. Morgenstern, Director for the Office of Policy Analysis within the Office of Policy and Resources Management, leads this group. Membership includes Dr. Anderson and Dr. Kuzmack (who had prime responsibility, respectively, for risk assessment guidelines and the draft cancer policy). The task force also includes senior representatives from the regional offices and each of the Assistant Administrators.

---

* I have included an article from a recent issue of "Science," which quotes a memo written by Mrs. Burford to the White House referring to cancer policy as "a policy this Administration is changing." The memo mentions this in reference to anticipated controversy over a decision on the pesticide permethrin. Frankly, I do not know what Mrs. Burford meant by this statement -- whether she refers to the still-continuing OSTP effort to revise cancer policy, whether she believed the permethrin decision itself embodied a change in cancer policy, or some other reason.

A number of key officials involved in the decision, such as Ed Johnson, the Director of Pesticide Programs, have testified that the permethrin action was consistent with previous agency policy. As part of our Toxic Integration Task Force (see next page) we did in fact review the risk management aspects of the permethrin decision, and found nothing unusual in its risk management policies (see enclosed report, referenced next page). The conclusion I draw is that Mrs. Burford's preference for case-by-case risk management policy certainly may have allowed for departures from TSPC policy, but we have no evidence that the regulatory judgment regarding permethrin departed from accepted policy.

February 1981

U.S. Environmental Protection Agency (EPA)
Office of Air Quality Planning and Standards (OAQPS)
Strategies and Air Standards Division (SASD)

RISK ANALYSIS PROGRAM PLAN AND ACCOMPLISHMENTS

In 1979, EPA's Science Advisory Board (SAB) Subcommittee on Health Risk Assessment recommended that OAQPS develop and "establish the credibility" of a risk assessment method for use in evaluating alternative national ambient air quality standards, and by implication recommended that EPA address how risk evaluation can best be incorporated into the standard-setting process. In late 1979, OAQPS started a Risk Analysis Program. This plan delineates both the projects undertaken since that time and those proposed for FY 1981-83.

For purposes of this program plan, risk analysis is broken into two components, risk assessment and risk evaluation. Risk assessment is the process of making risk estimates and describing the severity of harm associated with adverse events. Risk evaluation is the process of evaluating how much risk is acceptable in light of all relevant circumstances.

RISK ASSESSMENT

The primary objective of the risk assessment portion of the program is to choose a risk assessment method to use in assessing health risks associated with setting alternative national, ambient air quality standards (NAAQSs).* Main elements of the risk assessment program are:

- further development and evaluation of the F/B Risk Assessment Method.+
- development and evaluation of alternative risk assessment methods.
- investigation of issues related to risk assessment in general.

---

[*] It is recognized that there are possible outcomes of the program not as simple as the choice of a single "method." A possible outcome is that a general approach to doing risk assessments will be deemed appropriate no matter what the circumstances, and the particular method within this general approach judged to be appropriate will be a function of nature of the pollutant and time and resources the user chooses to expend in performing the assessment.

A spin-off of the program may be the identification of one (or more) risk assessment method(s) suitable for use in setting national emission standards for hazardous air pollutants (NESHAPS). The resources appropriate to spend for a NESHAPS risk assessment are presumably less than that for a NAAQS risk assessment.

[+] The F/B Risk Assessment Method is an approach to estimating health risks associated with alternative ambient air quality standards. It was developed by SASD analyst, Thomas B. Feagans, and a contractor, Dr. William F. Biller.

Specific projects have been and will be undertaken to address these three elements. Project summaries follow.

A. INVESTIGATION OF ISSUES RELATED TO ASSESSING RISK IN GENERAL.

The SAB Subcommittee and others have recommended that work be undertaken to address issues related to the use of expert judgment in assessing health risks associated with alternative NAAQS. These issues are common to the F/B and alternative methods currently under consideration. Another common problem is how should exposures to ambient air concentrations be estimated. A third general area of interest is to understand what issues should be addressed in a risk assessment and how other federal agencies currently address them. A brief description of past and proposed projects focused on these general issues and problems follow.

Completed Projects.

° Address behavioral psychology issues. The first project undertaken on issues associated with the use of expert opinion in assessing health risks of alternative ambient air standards was a review of empirical literature on subjective probability encoding. This review was undertaken by Drs. Thomas S. Wallsten and David V. Budescu of the University of North Carolina's Thurstone Physhometric Laboratory (Psychology Department). The review is published in:

Thomas S. Wallsten and David V. Budescu.
Encoding Subjective Probability: A Psychological and Psychometric Review. Research Triangle Park, N.C.: U.S. Environmental Protection Agency, 1980.

° Describe instrumental factors inherent in a NAAQS risk assessment. A small project was undertaken to describe factors that must be addressed in a health-focused risk assessment of alternative ambient air standards. The project also inventoried and classified existing non-carcinogenic health risk assessment approaches according to how they handled various conceptual issues inherent in assessing health risks. A typology of approaches was developed, focused on (1) output measures, (2) methods used to obtain output measures, and (3) inputs required.

This project was contracted to Dr. David Moreau, Professor of Environmental Planning, University of North Carolina. Results are contained in:

David Moreau.
Quantitative Risk Assessment of Non-Carcinogenic Ambient Air Quality Standards. Research Triangle Park, N.C.: U.S. Environmental Protection Agency, 1980.

° Describe Existing Risk Assessment Approaches Used by Federal Agencies. An inventory of "state-of-the-art" non-carcinogenic risk assessment approaches used by selective Federal agencies was pursued under another small project to Dr. David Moreau. The typology developed in the previous project was used to characterize and classify the various approaches. The inventory is contained in:

David H. Moreau and Mary Elizabeth Anderson. Quantitative Assessments of Health Risks by Selected Federal Agencies. Research Triangle Park, N.C.: U.S. Environmental Protection Agency, 1980.

° Estimate exposures to NO2 ambient air concentrations. An exposure analysis is an integral part of a risk assessment in that it provides the estimate of "dosage" seen by sensitive and normal population groups. A nitrogen dioxide (NO2) exposure analysis was undertaken in four urban areas, where population exposure was estimated using actual air quality information, population location data, and transportation movement estimates. In addition, indoor-outdoor relations of the pollutant were estimated and data on gas-stove usage was obtained to account for indoor exposure to NO2. Human activity level, which affects ventilation rate was also estimated. Exposure estimates, therefore, were time and space dependent and varied by population group, location, and physical activity. Sensitivity analyses were undertaken on key variables to understand their importance in contributing to total NO2 exposure.

The exposure analysis was done by the "SASD exposure team," consisting of EPA staff, Dr. William Biller and PEDCo Environmental, Inc., contractors. An interim report was written; it is:

Ted R. Johnson and Roy A. Paul. Analyses of Population Exposure to NO2 in Selected Urban Areas. Research Triangle Park, N.C.: U.S. Environmental Protection Agency, 1981.

On-Going Projects

A-1. Investigate behavioral psychology issues.

Dr. Thomas Wallsten of the University of North Carolina is undertaking an experimental investigation into two important issues associated with the use of expert opinion in setting ambient air standards. They are: (1) the question of "stability" of encoded probability judgments over time, and (2) the related question of the degree of randomness in encoded probability judgments by the means of encoding two corresponding dose-response probability surfaces.

Dr. Wallsten will present his findings in an EPA report. Completion date: October 1981.

A-2. Estimate exposures to SOx/PM/and CO ambient air concentrations.

The exposure analysis already developed for NO2 will be modified and applied to three additional pollutants, sulfur oxides (SOx), particulate matter (PM), and carbon monoxide (CO). In essence, three separate exposure analyses will be produced. Further methodological development of exposure modeling is the main purpose of this project from the risk assessment program perspective. The analyses will also be used in review of existing standards for the three pollutants.

Depending upon whether CO or ozone is chosen as the pollutant of interest in Project C-1, below, the CO exposure analyses may be used to further develop the F/B and alternative approaches risk assessment methods.

The SASD exposure team is undertaking all analyses in this project. Three reports are expected, one for each pollutant. Report due dates are: CO, July 1981; SOx, September 1981; PM, October 1981.

Future Projects

A-3. Estimate exposures to O3 ambient air concentrations.

Again, the SASD team will modify and improve its exposure analysis by applying it to ozone (O3). This project may be substituted for the CO part of the A-2 Project, if O3 is chosen as the pollutant of interest in Project C-1. A report will be the final product; it will be finished in late 1981.

A-4. Develop evaluation criteria for Project A-6.

This project will be focused on developing explicit criteria against which the remaining risk assessment methods will be evaluated in Project A-6. It will be done largely by SASD staff, with input from the SAB Subcommittee on Health Risk Assessment and Argonne National Laboratories. This project will be undertaken in mid-1982.

A-5. Estimate exposures to Pb ambient air concentrations.

A full-scale exposure analysis of lead (Pb) will be undertaken in four major U.S. urban areas. Results from this project will be extrapolated to the nation as a whole to obtain estimated national population exposures to this pollutant. This analysis provides inputs into the application/evaluation project. (Project A-6). The project will be undertaken in late 1982.

A-6. Apply and evaluate (the remaining) risk assessment approaches.

This project will be a "third-party" technical application and evaluation of the risk assessment approaches still under consideration by OAQPS in mid-1982. (There will be three at most; if there is only one, this project will not be undertaken). It is proposed to use lead as the subject pollutant and to possibly use results of this project in OAQPS's NAAQS-review effort. It is proposed to use the Decision and System Sciences group in Argonne National Labs as the third-party contractor. All developers of risk assessment approaches still under consideration will be directly involved in this project, doing specific tasks related to their particular approach under Argonne's general guidance. Argonne will prepare a report on its technical evaluation. The approximate completion date for this project is June 1983.

A-7. Review the application project and evaluate policy implications.

The purposes of this task are to review findings of Project A-6 and choose a risk assessment method (or methods) that will be used in the NAAQS-setting process. As part of the review, OAQPS--with assistance from OPE*--will evaluate policy implications of using the risk assessment method(s) found to be technically adequate. The project will be done in-house in mid-1983.

A-8. Investigate how risk assessment outputs can be best presented to EPA managers and the public.

Two interrelated questions will be addressed: first, how to best present results of a risk assessment to EPA decision-makers; second, how to best inform the public about health risks associated with alternative air standards. This project will be undertaken in mid-1983 by SASD, with perhaps some assistance by an outside contractor. The project must be closely coordinated with project D-4.

---

*Office of Planning and Evaluation in EPA headquarters.

B. DEVELOPMENT OF THE F/B RISK ASSESSMENT METHOD

The SAB Subcommittee made several suggestions with regard to work that would aid development, explanation, and evaluation of the F/B method. The following series of projects is designed to continue development of the F/B method in a way that will be responsive to suggestions of the Subcommittee. (Note: work of a general nature that was suggested by the Subcommittee appears in Section A, above.) Future projects in this section are contingent upon receiving a "decision to continue" from OAQPS in the Spring of 1981. This decision will be based upon results of the technical review project (Project B-2) and other evaluations.

Completed Projects

There were a number of projects and papers completed on the F/B method prior to institutionalizing a formal OAQPS risk program. These are not delineated here. In 1980, F/B had a paper published that discusses their view concerning the nature of probability estimates suitable for regulatory risk assessment. This paper is: Thomas B. Feagans and William F. Biller. "Fuzzy Concepts in the Analysis of Public Health Risks," pp. 391-404 in: Paul P. Wang and S. K. Chang (eds.), Fuzzy Sets (New York: Plenum Press, 1980). In addition, both gentlemen presented papers related to specific aspects of the F/B method at meetings and conferences during 1980.

On-Going Project

B-1. Complete "A General Method for Assessing Health Risks Associated With Primary National Ambient Air Quality Standards."

This project essentially involves completing a major report describing the F/B approach to regulatory risk assessment. The report is scheduled for completion in March 1981.

Future Projects

B-2. Conduct a technical review of the F/B approach.

Four-to-six-experts in probability theory, risk analysis, and air quality analysis will be engaged to provide an in-depth technical review of the F/B approach. Their review will focus on the report produced in Project B-1. The technical review will occur in late April and early May, 1981. The document will be released publically simultaneous with this review. Results of the review will be presented to the SAB Subcommittee on Health Risk Assessment in May 1981.

OAQPS will evaluate comments received from the reviewers, the SAB Subcommittee, and the public. Based upon this evaluation, OAQPS will make a decision whether or not to continue developing the F/B approach to regulatory risk assessment. The remaining projects in this category are contingent upon receiving a decision to continue from OAQPS management.

B-3. Publish peer-reviewed papers explaining various aspects of the F/B method.

Mr. Feagans and Dr. Biller, with assistance from other EPA staff, will write and submit papers on the F/B method to peer-reviewed journals. This is an on-going intermittent project starting after the OAQPS evaluation is completed.

B-4. Apply the F/B approach to CO.

This project involves a full scale application of the F/B approach to carbon monoxide. It includes modules to: select experts, conduct panel meetings to exchange health information, encode experts, develop probabilistic models and software, and produce "benchmark" and "headcount" risk estimates. The application will generate a more complete risk picture than was possible with the initial application to ozone; outputs will include both headcount and benchmark risk estimates.

This project will be undertaken by Mr. Feagans and Dr Biller, with assistance from Dr. Wallsten and PEDCo Environmental. The project will begin in early 1982 and should take about six months to complete. The main output is a report that will be used by OAQPS to determine if the F/B approach will be further considered in Project A-6.

C. DEVELOPMENT OF ALTERNATIVE RISK ASSESSMENT METHODS

The SAB Subcommittee recommended that OAQPS formulate alternative quantitative approaches for assessing risk. The Subcommittee wanted the Office to involve a number of outside experts in developing these alternative methodologies. This part of the risk assessment program is intended to address those recommendations.

Completed Project

- The first project undertaken in developing alternative risk assessment approaches was a highly-interactive effort involving six distinguished researchers and groups. Purposes of the project were to (1) elicit and develop conceptual risk assessment approaches suitable for use by EPA in setting ambient air standards, and (2) narrow down these alternatives to 2-3 approaches for further development.

  A two-day open meeting was held to discuss risk assessment issues and how they could be formally addressed. Information was shared and views were exchanged; audience participation was encouraged and obtained. Another two-day public meeting was held by the SAB Subcommittee at project conclusion. All six groups presented and defended their approaches. Again, audience participation was high.

  The SAB Subcommittee formally reviewed the conceptual approaches and stated that two, and possibly another, warrented further development. The SAB review is contained in: "Approaches to Health Risk Assessment for Alternative National Ambient Air Quality Standards: A Report of the SAB Subcommittee on Health Risk Assessment." Washington, D.C.: U.S. Environmental Protection Agency, Science Advisory Board, 1980.

  The conceptual approaches were described in the following papers that will be combined by OAQPS into a single EPA report (due date from the printer: June 1981).

  Richard deNeufville and Marie-Elisabeth Pate.
  "A Conceptual Risk Assessment Procedure" (1980).

  Baruch Fischhoff and Chris Whipple.
  "Assessing Health Risks Associated with Ambient Air Quality Standards" (1980).

  H.O. Hartley, K.G. Manton, and M.A. Woodbury.
  "Estimation of Risk of Adverse Health Effects Associated with Air Quality Standards for Pollutants" (1980).

M.W. Merkhofer.
"A Procedure Based on Decision Analysis for Assessing the Health Risk Associated with Alternative Ambient Air Quality Standards" (1980).

Howard Raiffa and Richard Zeckhauser.
"Reporting of Uncertainties in Risk Analysis" (1981).

Robert L. Winkler and Rakesh K. Sarin.
"A Risk Assessment Methodology for Environmental Pollutants" (1980).

Future Projects

C-1. Development of alternative risk assessment methods.

This project includes tasks designed to both further develop and apply the two conceptual approaches found by the SAB Subcommittee and OAQPS to be most promising for NAAQS purposes. The pollutant of interest will be either CO or O3. All exposure work needed for the assessment will be done by the SASD exposure team (see Projects A-2 and A-3).

Contractors for this project will be SRI International, who will develop Dr. M.W. Merkhofer's risk assessment approach, and Woodward-Clyde Consultants, who will develop Drs. R. Winkler and R. Sarin's approach. (The two professors are consultants to Woodward-Clyde; Dr. Ralph Keeney of the firm will also be involved in the effort.)

Each group will describe its methodology and the rationale behind it in a report; it will also describe output measures used and all inputs required. Technical appendices to the report will document algorithms and statistics used in the method, as well as its application to a specific pollutant. Finally, both research groups will evaluate their method for suitability and usefulness in a formal decision analysis approach to setting ambient air standards. (The final report is due in January 1982).

The approaches will be presented in an open session of the SAB Subcommittee. EPA will invite the Subcommittee to make recommendations concerning which method(s) should be evaluated further by Argonne National Laboratory in Project A-6.

This concludes the risk assessment part of the risk analysis program.

D. RISK EVALUATION

The main objectives of the risk evaluation portion of the program are to (1) determine the extent to which formal evaluation analysis can be used in the NAAQS-setting process and (2) develop a feasible risk evaluation approach that is compatible both with whatever risk assessment method(s) is (are) chosen for use in estimating health risks and with EPA's air programs mission.

Specific projects already completed and planned for to advance risk evaluation of NAAQS follow:

Completed Projects

There were two small projects undertaken in 1980 relating to risk evaluation. Both were with Dr. Ralph L. Keeney of Woodward-Clyde Consultants. The first involved an evaluation of how currently-generated information could best be analyzed and presented to EPA decision-makers. The emphasis was on the use of decision analytic aids in EPA's NAAQS standard-setting process.

The second project involved a trial application of decision analysis methodology to a specific NAAQS pollutant: carbon monoxide. The application was quite limited due to bugetary constraints.

Results of the two projects are contained in:

Ralph L. Keeney.
"A General Decision Framework for Primary NAAQS-Setting decisions" (1980).

Ralph L. Keeney and Vladimir M. Ozernoy.
An Illustrative Analysis of Ambient Carbon Monoxide Standards. Research Triangle Park, N.C.: U.S. Environmental Protection Agency, 1980.

On-Going Projects

D-1. Describe existing conceptual approaches to risk evaluation.

This project involves a critical literature search of conceptually distinct ways posited to evaluate policy and societal implications of risk associated with governmental programs. The project addresses such issues as choosing an adequate margin of safety, using risk-benefit analysis (or one of its variants), and explicitly evaluating a decision-maker's trade-off function. The project will be undertaken by Dr. James Vaupel of Duke University. Output will be a report describing findings. (This may be combined with the report developed for Project D-2.) The due date is August 1981.

D-2. Describe existing risk evaluation/decision analytic approaches used by federal agencies.

A literature search and site visits will be undertaken to determine what risk evaluation methods are currently being used by Federal agencies involved with the Interagency Regulatory Liaison Group. In addition, the extent to which risk evaluation is part of a broader decision analytic framework will be investigated and described. Findings will be published in an OAQPS report (which may be combined with the D-1 report). Report due date is August, 1981.

Future Projects

D-3. Develop criteria/constraints on the use of risk evaluation in the NAAQS-setting process.

This project essentially involves developing a "White Paper" describing what types of evaluation criteria are appropriate to use in setting air standards. It will also discuss legal/procedural/resource constraints facing the Agency in evaluating risk associated with alternative air standards. This is an in-house project with extensive staff involvement. It will begin after revisions to the Clean Air Act have been made, which is expected to be in the Fall of 1981.

D-4. Develop a risk evaluation method for appraising alternative NAAQS standards.

This project is designed to develop an integrated risk evaluation/decision analytic method suitable for use with the risk assessment method(s) found to be most appropriate for NAAQS pollutants. Both quantitative and qualitative aspects of decision analysis will be investigated as possible risk evaluation techniques. The project will be done under contract, and must be coordinated closely with Argonne's work on Project A-6.

The impact of using a risk evaluation methodology on other EPA programs and offices will also be addressed. Thus, SASD will cooperate closely with OPE and other interested Agency offices on this project.

Output will be a report. The project is slated to start in late-1982 and be completed in mid-1983.

This concludes the risk evaluation portion of the risk analysis program.

Guidance on Response to Contamination Detected in the Ground Water Supply Survey

The Office of Drinking Water (ODW) in cooperation with the States, is undertaking a national survey on the quality of ground water (The Ground Water Supply Survey). The survey is underway and it will include sampling and analyses of drinking water derived from ground water at 1,000 locations in the United States. The analytical procedures will identify purgeable halogenated organic chemicals such as the chlorinated solvents (e.g., trichloroethylene) and non-halogenated volatile aromatic hydrocarbons (e.g., benzene). Out of a total of 1,000 samples, 500 will reflect a random selection of sites. Another 500 sites will be selected by the States and EPA as areas with ground waters potentially contaminated by organic chemicals. Among other things, we will use this latter group to determine characteristics that may allow better predictability for locating contaminated sites.

The purpose of this guidance is to assist the States or other appropriate authorities in determining the type of response that they should make in a particular case where organic chemicals are detected in a sample from the survey. We are providing a perspective on the relative health significance of various concentrations of chemicals that might be detected, as well as information on the type and relative urgency of possible follow-up actions to protect the public. Depending upon the circumstances of a contamination incident, one of the appropriate actions could be to identify and control the source of contamination. There are ample legislative authorities for this purpose under existing pollution control legislation. However, such activities are not dealt within this guidance.

Two tables are attached which list a number of chemicals which may be detected in this investigation. The concentration levels in Table 1 reflect a scientific judgment on the health effects of specific chemicals using non-carcinogenic toxicity data. The values in Table 2 are based on the carcinogenic aspects of the chemicals. For each chemical, there are four concentration values listed, shown as categories I-IV. The categories represent differing degrees of concern and differing types of action that should be considered depending upon the level of concentration of the contaminants. Concentrations values are not listed for several of the chemicals; the Office of Drinking Water is continuing to collect and evaluate the available data and the tables will be revised as more information becomes available.

DRAFT

When an unregulated chemical is detected in drinking water, the EPA regional drinking water office should be contacted if assistance is required by the State. The Office of Drinking Water's Criteria and Standards Division (CSD) is also available to provide advisory assistance for case-by-case decisions. In instances where there is not a concentration value listed in the table, or an unlisted chemical has been detected, the CSD should be notified and every effort will be made to provide immediate recommendations. The person to contact is Dr. William Lappenbusch, phone 202-472-6820.

Both tables should be referred to when a chemical has been detected. For the same chemical, the concentration levels listed in the two tables in the same category may differ. This is due to the fact that each table was generated from a separate data base which used different toxicological end points. For certain chemicals, there may be questions as to which table to use and what level of concern is appropriate. Examples of the use of Tables 1 and 2 are given below:

- If trichloroethylene was found in drinking water and assumed to be consumed for approximately a year (chronic exposure) before remedial action was implemented, 0.075 mg/l (Table 1) would not pose significant health risks to the most sensitive members of the population. On the other hand, should the duration of the exposure be anticipated to last several years, then an attempt to reach concentrations between 0.005-0.045 mg/l (Table 2 would be used which is based upon carcinogenicity) may be more prudent depending upon population exposure, treatment and associated costs.

- In some cases, like carbon tetrachloride, the excess cancer risk number (0.045 mg/l for 10^{-5} lifetime risk) is provided but no chronic non-carcinogenic number exists since existing dose/response data are not available for the proper duration to allow for such an estimation. In that case, a reasonable approach would be to use the more conservative values in Table 2. In such instances the State should contact the CSD and advice will be provided based upon the specific toxicity of the chemical, the length of exposure, and other factors.

- In the situation where several chemicals are detected in the same water sample, a reasonable approach would be to treat the carcinogenic risks as additive (Table 2). For example:

DRAFT

- If trichloroethylene (TCE) and tetrachloroethylene (PCE) were found in drinking water at concentrations of 0.045 mg/l and 0.035 mg/l, respectively, the excess cancer risk over a lifetime may be estimated as follows:

TCE		1×10^{-5}
PCE	+	1×10^{-5}
Total		2×10^{-5}

  The total risk for these elements would still be in Category II of Table 2.

- If TCE and PCE were found at concentrations of 0.225 mg/l (5 x 0.045 mg/l) and 0.210 mg/l (6 x 0.035 mg/l), respectively, the excess cancer risk may be calculated as follows:

  Step 1

  TCE $5(1 \times 10^{-5}) = 5 \times 10^{-5}$
  PCE $6(1 \times 10^{-5}) = 6 \times 10^{-5}$

  Step 2

TCE		5×10^{-5}
PCE	+	6×10^{-5}
		11×10^{-5} or 1.1×10^{-4}

- The total risk for these chemicals would now be in Category I of Table 2.

Addition of the two or more calculated risks is obviously simplistic, but at least it provides a reasonably consistent decision process, assuming that other factors are not mitigating. However, there is a potential for synergestic effects and simple addition of the risks of each carcinogen could thereby underestimate the overall risk.

For mixtures of non-carcinogens, none of which exceed the concentrations in Category III of Table 1, the CSD should be consulted.

DRA

In the case of trihalomethanes (THM) being detected, an MCL of 0.10 mg/l is included in the National Interim Primary Drinking Water Regulations. This value was derived taking economics and technical feasibility into account and levels above the MCL should be handled according to normal State procedures. Since THMs are a by-product of the chlorination process, detection of THMs in the raw water would indicate contamination of the ground water; depending upon the circumstances at each site, the source of contamination should be identified and controlled.

Table 1 - Acute and Chronic Toxicity Factors

The values in Table 1 are computed from acute, short-term and chronic toxicity considerations (Categories I, II, III, respectively). Category IV values are based upon taste and odor detection data and do not include toxicity factors. This compilation was derived from a number of sources, including Office of Drinking Water SNARLs (Suggested No Adverse Response Levels), recommendations from the National Academy of Sciences (NAS) report, Drinking Water and Health (1977), and other literature as evaluated by the CSD. Those concentration levels in Table 1 which are not identified by asterisks were prepared by the ODW. The other levels, identified by asterisks, were calculated from values delineated in the National Academy of Sciences report or EPA Ambient Water Quality Criteria Documents (1980).

The categories, values and suggested follow-up responses for Table 1 are as follows:

Category I. Acute Concern Level, High Risk

This is an unusually high concentration level that may introduce risks from brief exposure (one or a few days) in high risk individuals.

Even though large safety margins normally are included in the computed values, emergency type action should be taken.

- Immediate resampling and verification of the concentration levels.
- Identification of the source of contamination and rectify problem, if possible.
- A ban on water consumption for drinking and cooking.

DRAFT

Category II. Subacute Concern Level

This is a high concentration level but the concentrations are about 1/10 of Category I. Action should be immediate.

- Immediate resampling and verification of the concentration levels is essential.
- Identification of the source of contamination and rectify problem if possible.
- A ban on water consumption for drinking and cooking should be considered, especially if the level is likely to persist for more than approximately 10 days.
- Alternate sources should be seriously considered as well as treatment to reduce the levels.

Category III. Chronic Exposure Concern Level

Exposure near this level for an extended period would represent a relatively low risk situation, especially if the chemical is not bioaccumulative.

As soon as practical, the following actions are appropriate:

- Resample and verify concentration levels.
- Identification of the source of contamination and rectify problem if possible.
- Initiate long term surveillance monitoring, as concentrations may increase in the future.
- Alterations in the treatment process or consideration of alternate sources.

Category IV. Taste and Odor Detection

Detection by taste or odor usually causes public rejection of the water for drinking and cooking uses and may indicate severe contamination and a potential imminent health risk (e.g. the case of benzene where the taste and odor threshold is 2 mg/l but the acute number is 0.35 mg/l). In some cases, the taste and odor levels listed in Table I are lower than the Category I, II or III levels and therefore provide protection as in the case of 1,4-dichlorobenzene. In either case, the cause should be identified and corrective action taken.

DRAFT

Table 2 - Potential Carcinogenic Risks

The concentration levels in Table 2 for the potential carcinogens are derived from risk extrapolations from the NAS's Drinking Water and Health report, or from EPA's Carcinogen Assessment Group (CAG). The Crump multi-stage model was used, and the computed incremental risks assume lifetime (70 years) consumption of 2 liters of water per day containing the chemical at the indicated level. No additional exposures to the chemicals other than in drinking water are considered in these values.

Both the NAS and CAG numbers were included in this table to indicate that risk estimation represents a scientific judgment as to the health risk resulting from a chemical's presence in water. The two values are not identical because different data and parameters were included in each model. For example, the trichloroethylene concentrations associated with a lifetime exposure and cancer risk of 10^{-5} via the CAG and the NAS at the 95% confidence limit are 0.028 mg/l and 0.045 mg/l, respectively. However, for the majority of chemicals, the two values are fairly consistent and indicate the general range of concentration levels that would elicit a response action.

For the purpose of providing advice on the types of follow-up actions that would be recommended when certain levels of contaminants are found, four categories were arbitrarily selected as a means of indicating relative concern levels based on the lifetime risks at these concentrations. It is emphasized that these values are projected from lifetime exposure, and therefore, response actions usually would not be commensurate with risks from relatively short exposures.

The categories, excess cancer risk levels and suggested responses for Table 2 are as follows:

Category I. Projected Lifetime Exposure Risk Larger than 1 in 10,000 (> 10^{-4})

This is a situation which would represent a high priority; because of the relatively high concentrations in some cases, immediate action may be warranted (non-carcinogenic vs. carcinogenic data should be compared and other factors such as population exposure, duration of exposure, treatment and associated costs should be evaluated).

- Resample and verify concentration levels.

DRAFT

- Identify source and rectify problem if possible.
- Consideration given to:
    - switching to alternate source
    - banning water for cooking/drinking purposes

Category II. Projected Lifetime Exposure Risk Between 1 in 10,000 and 1 in 100,000 (10^{-4} - 10^{-5})

This is a situation that would represent a high priority concern, but somewhat less than Category I and should generate expeditious action.

- Resample and verify concentration levels.
- Identify source and rectify problem, if possible.
- Take steps to reduce human exposure.
- Initiate frequent monitoring.

Category III. Projected Lifetime Exposure Risk Between 1 in 100,000 and 1 in 1,000,000 (10^{-5} - 10^{-6})

This is a relatively lower risk situation that would not require accelerated action. Action should be taken as resources permit.

- Resample and verify concentration levels.
- Identify source and rectify problem if possible.
- Long range surveillance monitoring should be considered because concentrations could increase in the future.

Actions should reflect whether the concentration value detected is at the higher or lower part of the risk range.

Category IV. Projected Risk Less than 1 in 1,000,000 ($< 10^{-6}$)

This is a concentration level that represents a negligible risk; this situation should be considered to be low priority.

DRAFT

- Depending upon available resources:
  - Resample and verify concentration levels.
  - Investigation of the source of contamination and possible rectification of problem.
  - Long range surveillance monitoring should be considered because concentrations could increase in the future.

DRAFT

Table 1: Concentration Levels (mg/l) for Select Chemicals, Based on Toxicity Other Than Carcinogenesis

Chemical Name	Acute I	Short-term II	Chronic III	Taste and Odor IV
Benzene	0.35			2
Carbon Tetrachloride	0.2	0.02		
Chlorobenzene			0.072**	0.1

OFFICE OF
WATER

SUBJECT: Request for Review of Draft Cancer Policy Statment

FROM: Arnold M. Kuzmack, Director Arnold M. Kuzmack
Office of Program Development & Evaluation, ODW (WH-550)

Elizabeth L. Anderson, Director
Office of Health & Environmental Assessment (RD-689)

TO: TSPC

This memorandum reports on progress by the Cancer Policy Task Force in its effort to develop meaningful statements of principles for use in controlling human exposures to carcinogens. Attached for your consideration at the July 31 meeting is a draft statement on cancer policy worked out by the task force. As the draft shows, and the discussion below explains, in various areas the task force did not reach consensus. In one of the two areas in which policy principles were developed, two options are provided because the task force was unable to agree. Individual members do not support certain portions of the reasoning, or certain emphases. However, all agree that it is appropriate to submit this draft to you at this time for your review and further guidance.

Specifically, we solicit your views on the following:

- The policies laid out in Parts III and IV.
- Other areas in which you wish us to attempt to articulate policy or decision rules (or alternatives).
- The background generalities and lines of reasoning in the draft.
- Is the extent of detail and explanation about right, too much or too little?
- Is the statement as a whole both useful and appropriate to the broad range of Agency programs and activities? (See two unresolved issues discussed at end of this memo).

In addition to discussion at the TSPC, we would be most grateful if individual members would provide us with written responses to help us in coming up with a final draft.

We were charged with developing recommendations on two questions:

(1) The weight to be given to individual risk vs. total population risk in Agency decision making, and

(2) Whether the Agency should adopt a target risk level for control of carcinogens.

It proved exceedingly difficult to articulate a useful set of generally applicable principles as a result of the differences in program experience and perspective that one would expect in a controversial area such as this. In addition, the differing decision criteria and requirements of EPA's authorizing statutes and many extra-statutory decision criteria tend to confound attempts to formulate simple, generally applicable principles based on cancer risk alone.

The attached draft is thus limited in scope, and at this stage hedged about with conditions, despite the very substantial amount of effort devoted by the members of the task force. The task force addressed the first of the two question only in the context of setting priorities for investigation of potential actions, since we did not think we could make a useful general statement about how to make final decisions in situations where a small number of people are exposed to a high individual risk. In this context, two alternative statements are offered (see pages 7 and 8. Option A indicates that the Agency will emphasize situations of high total population risk and will generally assign a lower priority for Federal regulatory action to situations of low total population risk and high individual risk. Option B give equivalent weight to both high individual risk and high total population risk. The group was not able to reach a consensus on which of these options to recommend and was about evenly divided on this issue. Some group members expressed reservations about the desirability of including the numerical illustration shown as part of Option B and felt strongly that the general statement may be much more acceptable without the specific numerical references. Others felt that without numerical examples the usefulness of the statement was largely vitiated.

With respect to the second question, the group considered an array of options involving risk targets, floors, and ceilings, both as single numbers and as ranges. The task force consensus was that the general positions on page 10 is supportable and that any statement which went further would not be supportable. The task force rejected the notion of a risk target in favor of a risk "floor", that is, a risk level below which the Agency generally would not go in controlling carcinogens. We felt that we could not give guidance that would be both specific and generally applicable as to how close Agency actions would get to the "floor". We have tried to state very clearly that the level is not a target and that particular actions will frequently result in a higher level of risk after control. While the task force reached a consensus on the recommendation of a risk floor, some group members disagree with the final paragraph of the draft and would delete as irrelevant and as conveying an unwise impression the statement that the risk level after control would "sometimes be much greater" than the floor. There was also a general feeling that this language would be much less acceptable if the level at which the floor was set, 10^{-6}, were to be changed to a much higher level such as 10^{-5} or 10^{-4}.

Two additional important issues were addressed by the task force only at the end of our last meeting, and hence were not considered in sufficient depth to provide a basis for resolving them in the draft submitted with this memo. We solicit your guidance on these issues. The first issue is whether the two policies stated in the draft should apply to all Agency control actions dealing with the hazards of carcinogens, or just to decisions on prospective controls. Should they apply not only to the prescribing standards or practices before environmental discharges have taken place, or also to the steps to be taken to deal with discharges to the environment after they have taken place and require cleanup or other action? Should these policies be extended to guidance as to how to deal with existing environmental problems (e.g., SNARLs), to advice to State officials in emergencies, to cleanup decisions under Superfund, to enforcement actions? Or should they be limited to regulatory-type standards typified by effluent guidelines, drinking water standards, and air new source performane standards? Part of the group felt there was no good reason not to apply these policies to all such actions; others felt that it was unwise, or at least not sufficiently thought through to recommend. The draft as submitted to you generally applies to all control actions, both preventive and cleanup, but we agreed to flag the issue for your guidance.

The second issue is whether the policy should apply to carcinogens one-by-one or should apply to the mixture of carcinogens found in the industrial source or other problem to controlled. Some task force members felt that where a given action would control exposure to several carcinogens, the two policy positions should apply to the aggregate risk of cancer presented by the several carcinogens. Others felt that the policy positions had been prepared on an assumption of dealing with a single carcinogen. While there was a tendency toward the former position, it was agreed that the issue deserved a more careful consideration with respect to the two policy statements.

The task force earnestly solicits your comments on the issues raised above, the draft policy statement, and the general direction of further effort.

EPA POLICY GUIDELINES ON THE CONTROL OF CARCINOGENS

I. INTRODUCTION

Cancer is a major problem from both a health and economic point of view. Chemicals in the environment cause an unknown but perhaps substantial number of cancer cases, and the identification of known and suspected chemical carcinogens is increasing with the passage of time. In order to ensure that the Agency is according an appropriate priority to carcinogenic chemicals for study and control, EPA has formulated the general approach set forth in Section III below. To set a point beyond which control of carcinogens is generally not appropriate, the Agency has developed the statement in Section IV.

EPA is authorized to control carcinogens under a number of statutory provisions. Some of the statutory provisions make risk reduction the predominant decision-making criterion; some focus on technology to reduce risks; and others require decision-makers to balance the costs and benefits of possible regulations (or the risks of a chemical and the benefits of its use). These different statutory provisions are among the reasons that the regulation of carcinogens is a highly complex matter.

One important issue that has arisen in connection with the control of carcinogens is whether and how to use quantitative risk estimates.

In 1976, EPA published interim guidelines on cancer risk assessment[1] which stated, among other things, the Agency's intention to use quantitative risk estimates when making decisions on chemical carcinogens under certain statutory provisions. These guidelines remain in effect. Since their publication, the Agency has had a great deal of experience in the use of quantitative risk estimates and now believes that it is appropriate to make some further general policy statements on the use of these risk estimates.

Therefore, in order to improve the decisionmaking process and make the control of carcinogens more consistent, the Agency has established benchmarks to be used in conjunction with other relevant factors in the control of carcinogens. They are intended to achieve reasonable goals consistent with the requirements of the various statutes which the Agency implements and the principles of E.O. 12291.

II. NATURE OF CANCER RISK ESTIMATES

Cancer risk estimates contain two basic components: an evaluation of the weight of evidence that a chemical is a carcinogen, and, assuming that it is a carcinogen, an estimate of the magnitude of the cancer burden resulting from it. The latter estimate (the quantitative risk estimate) is derived from a chemical's potency as a carcinogen and the numbers of people exposed to various levels of the chemical.

---

1. 41 FR 21402, May 25, 1976.

The analysis of human exposure will involve an estimate of the size of the exposed population and the level of exposure. The analysis may also consider such factors as exposure sources, routes, and conditions; the duration, frequency, and intensity of exposure; and the relevant characteristics (e.g., age, sex, and health) of the exposed population.[2]

The assessment of cancer risk resulting from a given exposure is characterized by great uncertainty, because of frequent limitations in the evidence of carcinogenicity and because of the necessity of extrapolating results from experimental animals to humans, from high doses to low doses, and (if human evidence is available) from one population group to another. The evidence of a chemical's carcinogenicity and of its potency will, in most cases, consist principally of the results of animal tests performed at doses much higher than those to which humans are exposed in the environment. In a few cases, adequate epidemiological studies may also be available, but these also usually involve exposures at high

---

2. Recognizing the complexity of estimating exposure, EPA is preparing procedural guidelines for the preparation of exposure assessments. The guidelines are intended to provide a general approach and framework for performing human and nonhuman exposure assessments, as well as to promote consistency, to the extent possible, in the data used, in the assumptions made, and in the presentation of ranges of estimates.

levels. In order to estimate the likely effect of exposure at much lower levels, perhaps by several orders of magnitude, mathematical extrapolation must be used.[3]

Any assessment of the effects of low exposures to carcinogens based on animal tests necessarily involves an extrapolation whose accuracy cannot be verified by existing scientific data. Accordingly, quantitative risk estimates are subject to a wide range of uncertainty. However, the only alternative to using these estimates is to attempt to make decisions without any estimate of the magnitude of the effects the Agency is attempting to control; this alternative is clearly much less desirable. Hence, despite these uncertainties, it is necessary to use estimates of the magnitude of the cancer risk along with other factors to make sensible regulatory decisions.

Because of the importance of many factors other than the degree of cancer risk, EPA may (to the extent permitted by law) rely on both risk and other considerations in reaching decisions on whether to attack a particular problem involving cancer risk, whether to implement controls for specific

---

3. Because it is not possible to identify a level of exposure to a carcinogen that would totally eliminate risk, the mathematical extrapolation models used by EPA assume that there is no threshold to the action of a carcinogen. The models assume, further, that the probability of response is proportional to the dose at low dose levels.

for specific sources and, where the pollutant is emitted from many sources, which sources to control and in what order. Although cancer risk is the focus in this statement, other factors may be more important in a particular case. Other factors that may be considered along with the reduction in cancer risk include:

- feasibility of control;
- control costs;
- benefits of the compound or activity that may be lost through control;
- presence of other toxic pollutant emissions;
- availability of regulatory resources;
- alternatives to federal control action (e.g., voluntary or state action, technical assistance, and provision of information);
- status of implementation of other regulatory programs;
- other health and environmental effects;
- multimedia (e.g., air, water, solid waste) sources and cross-media impacts;
- impact on the controlled industry and the economy; and
- legislative authorities and constraints.

When pollutants enter the environment via multiple routes or when exposure occurs from more than one medium, consideration will be given to implementing a coordinated multimedia, rather than a single-medium, control program since this may result in a more effective and econmical control strategy.

III. POLICY ON USE OF CANCER RISK ESTIMATES IN ESTABLISHING PRIORITIES FOR CONTROL ACTION

EPA is concerned about cancer risk to individuals because it is inequitable for some individuals to bear very large risks, often without choice and with little or no compensating benefits, even if other members of society benefit from the risk-producing activity. EPA is also concerned about the magnitude of total (nationwide) risk to the population as a result of exposure to a suspected carcinogen.[4/] Therefore, in establishing priorities to control exposure to carcinogens in the environment (whether by issuing regulations or other actions), EPA will consider both the magnitude of the risk to individuals and the total population risk.

Since decisions about the degree of control will depend on the costs and cancer risks as well as the requirements of the governing statute, a high priority for control does not necessarily imply that EPA

---

[4] Individual risk, as used in this statement, is the projected probability that an individual exposed to a given level of a carcinogen (or mixture of carcinogens) will develop cancer as a result of that exposure over the course of a lifetime. It is expressed as a probability,, e.g., a probability of one in a thousand (10^{-3}) or one in a million (10^{-6}). Total population risk is the expected number of cases per year projected to result from a given distribution of exposures and depends on both the levels of individuals risk in the population and the number of people subjected to those risks.

will take action to control the source. "Establishing priorities" means establishing the order in which EPA will examine the risks, costs, and benefits of control alternatives for various sources of carcinogens and the level of its own resources it will devote to this task. Hence, a "high priority" only means that EPA will consider a given control opportunity before others of lower priority. After examining the costs and benefits of control options, EPA may decide to proceed with national regulation or other Federal action, to encourage action by state or local government, to take other non-regulatory action, or to take no action at all because there is no feasible control alternative that results in significant risk reduction at reasonable costs. In some situations in which an exposure is limited to one or a few geographical locations, or is otherwise amenable to reduction by means other than Federal action, EPA may encourage voluntary actions or actions by State or local authorities and may use its resources to encourage such action.

Because data are generally limited at the early stages of decision-making, EPA will not do a detailed quantitative analysis in order to establish priorities. Moreover, while EPA will use readily available information, it will not necessarily delay priority setting to await additional analysis.

OPTION A

In general, EPA will set priorities for the control of carcinogens based principally on nationwide cancer effects. The Agency may also [illegible] high priority for national action to protect subpopulation groups at high risk, e.g., lifetime risks of 10^{-3} or greater. However, EPA will usually encourage action at the State or local level rather than issuing national regulations if individual risks are high but the number of people exposed (and consequently total population risk) is very small and geographically localized.

OPTION B

In general, high priority (as described above) may be supported either by a high level of estimated risk of cancer to small groups of individuals at greatest risk or by high total population risk. A combination of moderately high risk to individuals and moderately high total population risk may also support a high priority. While numerical levels of risk to define levels of priority will not be fixed, some examples may help. If, for instance, a relatively small number of people -- perhaps a few hundred -- were estimated to be subjected to a lifetime cancer risk in the vicinity of one in 100 (10^{-2}) to one in 1,000 (10^{-3}) by a given exposure, this could be the basis for high priority for considering action to reduce the risk caused by that exposure. On the other hand, if 10 million people were estimated to be subjected to an increased cancer risk of in the vicinty of one in 10,000 (10^{-4}) to one in 100,000 (10^{-5}), this also could be a basis for high priority.

IV. POLICY ON EXTENT OF REDUCTION OF CANCER RISK

Once a problem has been selected for control, a key issue is the stringency of control that the Agency should impose. There are no laws that call for regulation on the basis of achieving a specified level of risk (other than zero). Furthermore, there is no such thing as an acceptable level of risk _per se._ Risks are acceptable only in light of the benefits to be gained from the action that produces the risk or the cost of reducing the risk.

In theory, control decisions should be made based on a careful balancing of benefits and risks (under statutory provisions which permit such balancing). However, there are a number of considerations which have led the Agency to establish some risk benchmarks to guide its actions. There are a variety of situations in which there is not time for the lengthy process of rulemaking. For example, environmental contamination may require an immediate response (e.g., the Agency must determine whether people should be allowed to drink contaminated water). In other cases, state officials may want guidance on levels of pollutants that are not sufficiently widespread to justify the establishment of formal standards. In taking action under "imminent hazard" provisions of various statutes, EPA must make judgments about how serious particular risks are, and these may involve chemicals for which formal standards have not been established.

This policy statement will not attempt to articulate a "target" for risk reduction -- that is, a level to which EPA will generally try to reduce risk. It is useful, however, to articulate a level of risk below which EPA believes further effort to reduce risk is only infrequently justifiable (e.g., where there is no significant cost of additional control or no significant benefit from use of a chemical). This level is stated as follows: To the extent consistent with law, EPA will generally not attempt to reduce lifetime individual risk from particular exposures to carcinogens below one in a million (10^{-6}) for highly exposed groups of people. Risks below this level are widespread and are not generally perceived as significant by the public. Further reductions in such risks are not likely to be warranted from the point of view of competition for use of EPA's resources, nor feasible except at disproportionate cost.

This concept means that the level of individual lifetime risk after control may and frequently will be greater than 10^{-6}. Where the circumstances require, this level may sometimes be much greater. The actual level to which risk will be controlled will be based in each case on the statutory requirements and other relevant factors, as discussed in Section II.

OFFICE OF
PESTICIDES AND TOXIC SUBSTANCES

MEMORANDUM

SUBJECT: A Generic Work Plan or Guidance for EPA Study

FROM: Marilyn C. Bracken Marilyn C Bracken
Associate Assistant Administrator
for Toxics Integration (TS-777)

TO: John W. Hernandez
Deputy Administrator (A-101)

I have reviewed the attached studies as requested in your memorandum of October 5, and they appear to fall into two categories -- Group I - Multi-media/Intergrative studies and Group II - State/Regional support.

Group I - Memphis/Louisville

- These studies parallel the geographic approach that was studied by the Toxics Integration Project in the Kanawha Valley (Coordinated with Region 3).
- The Memphis/Louisville studies appear to have been initiated by the Region because of the potential environmental concern, and in some cases, some identified health effects.
- Both of these studies are likely candidates for the "Generic Approach" although I suspect that we could not establish sufficient evidence of exposure and/or potential exposure with existing data.
- The level of effort to complete these studies is greatly underestimated. I suspect their workload estimates do not project impact or need for headquarters support/review.

- I also suspect there are a number of such studies in the Regions that have been initiated that deserve identifying, tracking, reviewing, possibly stopping, etc. I think it is a rather sizable task to do this, but worth it in view of the time we end up spending if they get off track, and/or if they end up causing a great deal of Regional concern (e.g., Lead in Region VI).

Recommendation: I suggest we attempt to identify how many studies have been initiated in the Regions that fall in this Category I type. Furthermore, I recommend we review them, and determine the purpose for the study, the justification for the study, and establish a priority for continuing some of them, if appropriate.

Group II - Study Plans for Apalachicolo Bay, Brevard County and Hookers Praire.

- These studies are all some what different, but fall within the normal workload and purview of the Regional Administrators. They are one-time requests from State or Regional groups for technical assistance and advice. In general, I think the RA's must decide how their resources can best be spent to respond to these requests.
- Solutions to any problems in two of these three studies are state/local - i.e., waste load allocation and septic field leaching.

Recommendation: These studies are not candidates for Generic Analysis by Headquarters; they should remain within the decision-making authority of the RA's.

UNITED STATES ENVIRONMENTAL PROTECTION AGENCY
WASHINGTON, D.C. 20460

MEMORANDUM

OFFICE OF
WATER

DATE: April 9 1982

SUBJECT: Outline for Background Documents on Environmental/Human Health Effects and Risk Assessment.

FROM: Victor J. Kimm, Director
Office of Drinking Water (WH550) ?

TO: Merna Hurd
Associate Assistant Administrator for Water
Office of Water (WH556)

I have asked my staff to look at the outline for the 'Health Effects' report proposed by the sludge contractor, and compare it with other similar documents in use within the Agency. Having done so, some interesting findings come to light. For example, the term 'risk assessment' is not used the same way by different groups. Within the Office of Water we are using a definition ~~which recognizes risk analysis as the review and evaluation of hazard and exposure information for purposes of estimating the likelihood that the hazards associated with a substance will be realized in an exposed population~~. Within the assessment, as defined this way, there must be a presentation of the change in exposure and risk as a result of the alternative regulatory and non-regulatory control options.

However, having reviewed ODW's most recent criteria documents, there appears a section entitled 'risk assessment' which is actually a hazard assessment, as defined in the "Criteria For Evaluating Risk Assessment Documents", a copy of which you received at the end of our meeting last Tuesday. Other documents we reviewed misuse this term as well, so it is no surprise that the recommended outline from the contractor uses the term, leaving me in some doubt as to exactly what is intended in that section.

In order to most effeciently capture my staff's review of these documents, while providing you our best advice on the structure of the contractor's reports, there is a recommended outline for the report attached.

Specifically, the report should consist of ~~three major~~ sections, the health assessment, the exposure assessment, and the risk assessment. By breaking the report into these three sections, development of the first two can go on simultaneously. Naturally, the risk assessment can not be written until the other material is drafted. The report may be viewed as a three volume piece. The content and purpose of each section of the outline is included, and I believe this approach will best serve your efforts.

# RECOMMENDED OUTLINE
for

Background Documents on Environmental/
Human Health Effects and Risk Assessment

It is possible to view the material in these documents as three distinct reports which together constitute a complete document. This outline contemplates such an arrangement.

Summary

- Executive Summary
  This section should summarize all three basic reports. It may constitute the useful decision supporting report, and would be a stand alone overview of the three in-depth reports.

Health & Environmental Assessment

The purpose of this report is to review and evaluate the scientific data in order to characterize the health hazards that may be associated with exposure to a substance, and to ascertain the strength of the scientific evidence supporting the characterization.

- Introduction
  This section should briefly identify the uses, sources and ambient levels of the chemical. The purpose is only to introduce the chemical, not to discuss material which will be presented in the latter reports.

- Pharmacokinetics
  This section should cover absorption, distribution, metabolism and excretion in humans and other species, as appropriate.
  phytotoxic problems

- Mechanisms of Toxicity
  This section identifies the biochemistry of the toxicity within the species upon whom a toxic effect is observed.

- Health Effects in Animals
  This section discusses acute effects, chronic effects, teratogenicity, reproductive effects, mutagenicity, and carcinogenicity in the animal species for which there is data, and especially for those ~~animals~~ concerned, aquatic and marine species likely to be exposed.

- Health Effects in Humans
  This section discusses case studies and anecdotal data on acute and long-term effects, as well as controlled studies and epidemiology which may be available.

- Hazard Estimation
  This section will discuss the quantification of the carcinogenic risk, the thresholds for acute and chronic risks, the impact on sensitive populations, the Acceptable Daily Intake, and interactions of the chemical with other chemicals.

Exposure Assessment

The purpose of this report is to review and evaluate the scientific data which identifies the size and nature of the human and other species exposure to the chemical, and to estimate the frequency, duration and intensity of its exposure. In addition, the amount of the exposure which can be controlled, and the technology to control the exposure should be identified.

- Introduction
  This section should briefly identify the hazardousness of the chemical. The purpose is only to introduce the chemical, not to discuss material which will be presented in other reports.
- Mass Balance
  This section discusses the occurrence of the chemical in the various media from source to use or disposal.
- Plant Uptakes
  This section discusses the information and assumptions associated with estimation of uptakes in sensitive plant species and the food chain.
- Animal Uptakes
  This section discusses the information and assumptions associated with estimation of uptakes in sensitive species and the food chain.
- Human Uptakes
  This section discusses the information and assumptions associated with estimation of human uptake, indicating the contribution from all source media.
- Exposure Control
  This section identifies the nature and efficiency of technologies which can be used to control human, animal and ecosystem exposures to the chemical. Cost data can be included.

Risk Assessment

The purpose of this report is to review and evaluate the hazard and exposure information for purposes of estimating the likelihood that the hazards associated with a substance will be realized in an exposed population. Within this assessment, a presentation is made of the change in exposure and risk as a result of the alternative regulatory and non-regulatory control options.

- Introduction
  This section should briefly identify the hazard and exposure associated with the chemical. The purpose is only to introduce the chemical, not to discuss material which will be presented in other reports.

- Regulatory and Non-regulatory Policy Alternatives

  This section will identify the analytical construct of the assessment. It will organize the readers perspective with respect to the alternatives considered, discarded and discussed in depth.

- Base Case Risk Estimate

  This section will discuss the existing situation, and will use the hazard and exposure data to estimate the national risk. In addition, there may be significant differences in risk, depending on regional or local conditions. These differences will be identified, as appropriate. Lastly, in order to support benefit-cost analysis, the risk at the decision-makers level should be identified. For example, if one of the policy alternatives is to leave control decisions to local government, the base case risk to localities should be estimated in a systematic manner.

- Policy Alternative Risk Estimates

  This section will discuss the estimates of national, regional and local risk associated with each of the policy alternatives. The format of these estimates should permit comparison between the base case and the alternatives.

- Sensitivity Analysis

  This section should identify the critical assumptions in the risk analysis, including those assumptions which were made in the hazard and exposure assessments, if they are significant to the risk estimate. The sensitivity of these assumptions to the estimate of risk should be identified in a manner which permits the decision-maker a full understanding of the significance of the assumptions.

Should cross-walk this to RIA requirements

CRITERIA FOR EVALUATING RISK ASSESSMENT DOCUMENTS

General

Risk assessments describe the changes in risk to human health associated with potential reductions in human exposure as a result of alternative regulatory and non-regulatory actions.

At minimum, a risk assessment must present information on five elements:

I Hazard Assessment (HA): HA is defined as the review and evaluation of scientific data to characterize the health hazards that may be associated with exposure to a substance, and to ascertain the strength of the scientific evidence supporting the characterization.

II Exposure Assessment (EA): EA is defined as the review and evaluation of scientific data for purposes of identifying the size and nature of the human population that may be exposed to a hazardous substance, and to estimate the frequency, duration, and intensity of its exposure. from all routes.

~~III~~ Controllable Exposure (CEx): CEx is that exposure which is within the ability of technology to control. It sets the limit of a regulatory approach, and must be related to the total exposure due to all routes.

Has

yes!!

III Risk Assessment (RA): RA is defined as the review and evaluation of hazard and exposure information for purposes of estimating the likelihood that the hazards associated with a substance will be realized in an exposed population. Within the assessment, there must be a presentation of the change in exposure and risk as a result of the alternative regulatory and non-regulatory control options.

subset 8/10

Sensitivity Analysis (SA): SA is a discussion of the uncertainty within the risk assessment. Since exposure estimates nearly always require use of uncertain data and and assumptions, the effect of varying critical assumptions must be presented, along with a clear specification of the assumption, as well as whether uncertainty is due to data or judgement.

Should be a part of each 5 sections, [illegible] 23, it should [illegible]

Purpose of the Evaluation

The evaluation criteria presented below are intended to ensure consistency in risk assessments within the Office of Water. In brief, the evaluation will review the adequacy of health effects assessments, the completeness and appropriateness of critical assumptions, the manner in which uncertainty is reflected, the sensitivity of assessment conclusions to assumptions, the completeness of consideration of regulatory and non-regulatory alternatives, and the extent to which multi-media exposures are incorporated into the assessment.

References

Risk assessment is a rich field of study, and much has been written on how to conduct these analyses. Two references which are especially helpful, and which indicate both the development and use of an assessment are:

National Academy of Sciences, Decision Making for Regulatory Chemicals in the Environment, Washington, D.C. 1975.

Hirshleifer, J. and Shapiro, D.L., "The Treatment of Risk and Uncertainty", Public Expenditures and Policy Analysis, Haveman, Margolis: Eds., Markham Publishing Co., Chicago, 1970.

Criteria

The following criteria are for use when evaluating risk assessment plans, draft assessments, or final assessments. It is assumed that risk assessments are for use in the policy making process, and are available before regulations, guidances or policies are proposed.

1. Health Effects Component. Does the risk assessment contain a segment which identifies the health effects basis for the assessment? Does that segment reflect:

- A thorough literature search strategy containing the following essential elements:
  - a) recognized standard sources;
  - b) sources relating specifically to the subject under study;
  - c) all relevant machine-readable data bases (i.e. MEDLARS, Lockheed Information System's DIALOG, etc.).

  The presence of primary reference should be mandatory to prevent misinterpretations.

— [illegible] EA ?

- A careful review of computer printouts and selection of relevant citations for hard copy retrieval.

- A comprehensive discussion of pharmacokinetics including:
  a) absorption;
  b) distribution;
  c) metabolism;
  d) excretion;
  e) bioaccumulation.

Problems arising in evaluating the pharmacokinetics data at different doeses should have been addressed (i.e., alteration of the rates and the pattern of metabolishm in different species and strains of animals and among sub-groups of human populations, etc.).

- A detailed evaluation of health effects in animals and in humans.

  Systems and organs affected should be identified, and a correlation of exposure and effect should be discussed. Major findings from animals studies should be discussed under the following subheadings:

  a) Acute effects
    *LD(50) (lethal dose, 50% kill)
    *LD(LO) (lowest published lethal dose)
    *LC(50) (lethal concentration, 50% kill)
    *LC(LO) (lowest published lethal concentration)
    *and other short term effects on target organs.
  b) Subacute or Subchronic effects (time depedent).
  c) Chronic effects, including but not limited to:
    * carcinogenic effects
    * mutaginic effects
    * teratogenic effects
    * reproductive effects.

- Any analysis of animal toxicity studies should include basic information on:
  a) sex, species, age, and health of animals showing adverse effects;
  b) interactions with other chemicals (antagonistic and/or synergisitc effects);
  c) inter- and intraspecies variability in response;
  d) dose-response data for acute or longterm effects, with emphasis on threshold exposures;
  e) effects of possibly cumulative exposure.

- A careful evaulation of animal toxicity studies that elucidate the mechanism of toxic action, with particular attention given to the validity of subtle effects described from exposure of humans to the chemical.

- A critical examination of carcinogenesis/mutagenesis/teratogenesis tests results to detect any occurrence of false-negative or false-positive for a given chemical;

- A discussion of major problem areas such as:
  - a) conflicting reports indicating that further research is needed to determine the significance of a particular toxic action;
  - b) possibility of unconventional methods being used and insufficient data as to their reliability, accuracy, consistency, and validity;
  - c) validity of experimental design and statistical methods used in animal studies, controlled human exposures, etc.;
  - d) disagreement between epidemiological studies, clinical reports, and chronic toxicological studies;
  - e) complication of longterm health effects of exposure arising from environmental alternations, biogmagnification, and dietary variability, etc.

2. Exposure Component . Risk is a function of both the intrinsic toxicity of the chemical and the pattern of use projected for it. Does the assessment discuss the realistic expected human exposure to the contaminants? Does the exposure segment reflect:

- Actual or modeled changes in patterns of contamination;

- Relative exposure estimates for regulatory options, including alternative standards, the ambient condition, the relative contribution from other sources of the contaminants.

3. Reliability and Sensitivity . Without perfect information, assessments must depend upon estimates and may be written even though some information is not available, even as an estimate. Does the assessment deal with missing or unreliable data in a manner which still permits rational decision-making, or its analog, reasonable judgement? Does the assessment contain a segment which reflects:

- Estimates of data uncertainty;
- Development of 'estimated ranges of probable risk' which capture the probable risk, taking uncertainty into consideration;
- Specification of those parameters to which the assessment is most sensitive.

4. Analytical Parameters . Does the risk assessment use standard parameters which reflect the Office of Water and EPA policies? Do inconsistencies exist in use of:

- Safety factors;
- Extremely low exposure toxicity models;
- Distribution of sensistive populations;
- Ingestion, inhalation, other exposure estimates;
- Human and environmental contaminant pathways;
- Engineering and technological efficiencies.

5. Association with Policy Alternatives . Does the risk assessment present the estimated risk for each of the major policy alternatives? Are the major policy alternatives diverse and innovative or are they very closely related in scheme? Does this presentation reflect:

- Quantitative estimates;
- A 'best estimates';
- A 'range of realistic estimate';
- A 'range of all possible estimates';

6. Data Presentation . Does the assessment present the risk data in a manner which is useful to the decision-makers and outside reviewers? Does the presentation reflect:

- Simplcity in data presentation;
- Understandability to an educated public;
- Differentiation power for the assessment of policy alternatives;
- Inter-media and inter-regulation comparisons (relative vs. absolute risk)
- a distinguishing between scientific data and value judgement estimates.

Recommended Outline for a Sludge Risk Assessment

In reviewing the sludge materials, it appeared to us that the critical policy questions deal with how to safely and efficiently dispose of sludges. Specifically, which are the significant contaminants in sludes? How and to what degree can these contaminants be transported to humans as a result of sludge disposal applications? Are there distinctions between types and sources of sludges and their possible end applications? What cirteria and operating mechanisms can be established to properly control this program? Procedurally, what should be the process for completing the analysis of all these issues and thereby producing a final policy? From these questions it is possible to structure an outline for a risk assessment. The outline below is an initial suggestion which reflects our experience in dealing with these human health issues, but also reflects our lack of experience in dealing with sludges. The italicized section below each outline point is our best estimate of what is now available and what is missing. In many cases, the information exists, but is dispersed throughout several background documents. We recommend that the existing material be brought together, and only then should new analytical efforts be started. It is clear that a great deal of analytical work will remain, but the structure and even the modeling capability to do it are already in existance. Lastly, we recommend that your staff review our comments and improve this outline. We recognize that their background on this subject is greater than our own, and no doubt they can put their hands on much of this data quickly. As this information is pulled together, we would expect that some conclusions would become clear before all the questions are answered. There might be some disposal methods that are clearly acceptable and some others that are clearly not acceptable. The Agency could then make these decisions known while continuing to work on the remaining, more difficult problems.

1. Introduction and technical background

   [illegible]

   o Volume, content and sources of primary, secondary and post-digestion sludges.

   This information was not presented in the basic briefing materials. It is dispersed throughout the background documents, but even in those materials the breadth of the problem is not discussed. This introduction must go beyond the pre-treatment issue, although pre-treatment could be highlighted.

2. Health Considerations of Sludge Components

   o Contaminants with significant potential for adverse impacts on human health, animals, ecosystems, plants and crops.

Seven contaminants have received special attention, to the point where draft recommended contaminant levels have been developed. This list should be expanded with respect to other metals, organics, and especially bacterial and viral components of sludges. It may be that as ADI's are established, several of these chemicals will drop off the sludge related lists.

- Acceptable Daily Intakes for the significant contaminants, including all human exposures from air, water, food, and sludge disposal methods. This section would describe the exposure routes which exist, the relative importance of each, and the basic computation of each ADI. Criteria must apply to the aggregate concentration of the contaminants of the soil/sludge mix at the application site, and should not apply to the sludge component alone.

ADI's have been developed for several of these chemicals. It remains for the sludge related exposures to be compared with other exposure routes. This should be done quickly, as some of the chemicals may well drop off the list, due to the insignificance of the sludge component of human exposure.

- Non-human impacts of the significant contaminants, describing impacts on soil, plants and crops, food chains, domestic and non-domestic animals.

This has not been aggregated into a simple presentation, but much of the data do exist in the background documents.

- Specification of the critical contaminants and exposure routes, based on the preceding discussions. A comparison of exposure levels of these contaminants with background levels.

This is a critical step which, when done, may immediately support some of the proposed technical options. It will drive the discussion technical discussion, in that it will limit the need to discuss some technical options which could have been developed, and may exist in the discussion now.

3. Technical options

- Specify the efficacy and cost of the various disposal options, including incineration, ocean dumping, and the many different types of land disposal.

The efficacy and cost data have not been packaged, or were not in materials you provided us. It is important to key on the technical costs in this section. Some costs of disease treatment were presented, and they are a surrogate for the benefits which might be derived from various regulatory or non-regulatory options. However, they are not the costs of the treatment/control technologies.

- Indicate the current mix of the technical approaches in use, and the optimum mixes which could be suggested.

One mix of land applications has been presented (fertilizer/soil conditioner for an assumed set of markets). The use or disposal by other techniques is not discussed in any way. It may be that land disposal is singularly less efficient than other techniques, and that a ban should be proposed. This is not a suggestion, but indicates the extent to which lack of information constrains the policy maker, as insufficient information on competing disposal methods is presented to dispell that potential conclusion.

- o Assess the administrative feasibility of controling the various technical approaches described above.

Administrative feasibility has been left undiscussed. The state and federal implementation activities may limit the technical approaches available. For example, if there is to be an enforcement component of potential regulatory alternatives, the feasibility of such enforcement must be identified and presented.

- o Assess the cost of these technical approaches.

Models ~~apparently~~ exist to quickly aggregate technical costs. These should be reemployed as necessary to develop the costs of each of the technical approached developed.

- o Assess the risks associated with these technical approaches.

This has been done only for the baseline and a pre-treatment option. It must be expanded to consider other reasonable technical approaches such as ocean dumping and incineration. It appears that a model exists to assist in this process.

4. Regulatory and Non-regulatory Alternatives

- o Specify which of the technical approaches would satisfy the needs of the legislative mandates.
- o Present the regulatory and non-regulatory approaches which stem from the previous chapter and section, indicating the risk estimates associated with each, as well as the sensitivity of the critical assumptions which were applied to each approach.

This presentation is, of course, the key decision maker's section. This is what you are aiming for, and what you are now missing.

ADDITIONAL U.S. ENVIRONMENTAL PROTECTION AGENCY GUIDANCE FOR THE HEALTH ASSESSMENT OF SUSPECT CARCINOGENS WITH SPECIFIC REFERENCE TO WATER QUALITY CRITERIA

A. Introduction

This document proposes an addendum to the guidelines adopted in 1976* under which the U.S. Environmental Protection Agency (EPA) has carried out its risk assessments on suspect carcinogens. These guidelines call for a qualitative weight-of-evidence judgment concerning the likelihood that an agent is a human carcinogen. The weight-of-evidence approach entails a thorough review of all of the available data from animal bioassays, human epidemiology, metabolism data, and in vitro studies, both positive and negative, with judgments based on the scope and quality of the available evidence. The guidelines also call for quantitative estimation of the incremental cancer risks associated with given levels of exposure using several mathematical extrapolation models relating dose to cancer incidence.

In practice, no formalized system for stratifying the qualitative weight-of-evidence has been used. Frequently the term "substantial" has been used where the weight-of-evidence was greater than "suggestive," recognizing that the same term was being applied to strong evidence in some cases and relatively weak evidence in others. Alternate ways of expressing the weight-of-evidence were also employed.

With quantitative assessments, the linear non-threshold extrapolation

model has been used almost exclusively because it provides a plausible upper-limit estimate of low-level risks and no other extrapolation model has as much scientific acceptance. It has been recognized that the upper-limit risk estimates obtained by the use of the linear non-threshold extrapolation model, although plausible, involve large uncertainties and the true risk can range from the upper-limit to lower levels; i.e., approaching zero. Also, the plausibility of the linear non-threshold extrapolation model is predicated to a significant degree on the mutagenicity of carcinogens and not all carcinogens have this property.

In recent years there has been a growing awareness of the need to amend the EPA's cancer risk assessment guidelines (cited above) in two respects:

1) to adopt a formal approach that would stratify the weight-of-evidence judgments about the likelihood than an agent is carcinogenic for humans, and
2) to take mutagenicity into account in quantitative risk assessment.

Section B, which follows, proposes an approach for stratifying the weight-of-evidence for carcinogenesis. This is followed, in Section C, by a proposed approach to the quantitative assessment of suspect carcinogens according to the evidence for mutagenicity. Section D applies the above approaches to guidance on water quality criteria. Section E summarizes options to the proposed approach and guidance on water quality criteria.

B. Stratification of the Weight-of-Evidence for Carcinogenesis

Although there are various possible methods of stratifying the evidence for carcinogenicity on the basis of factors such as the number of studies done, the species affected, the target organs affected, or the background tumor rates in target organs, etc., only one approach has had extensive institutional use and international acceptance, namely, the one developed and used for several hundred agents by the International Agency for Research on Cancer (IARC). As with the current EPA approach to risk assessment, the IARC approach requires the collective judgment of experts, thus providing a reasonable balance between flexibility and a consistent set of ground rules for evaluating the evidence for carcinogenicity. For this reason, the IARC approach is proposed for use by the EPA; it is presented below as published by IARC* with two editorial changes indicated by footnotes.

B.1 The IARC Stratification of the Evidence for Carcinogenicity

B.1.1 Assessments of evidence for carcinogenicity from experimental animal studies

These assessments are classified in three groups:†

a. Sufficient evidence of carcinogenicity indicates that there is an increased incidence of malignant tumours: (a) in multiple species or strains, or (b) in multiple experiments (preferably with different routes of administration or using different dose levels), or (c) to an unusual degree with regard to incidence, site or type of tumour, or age at onset. Additional evidence may be provided by data concerning dose-response effects, as well as information on mutagenicity or chemical structure.

---

*IARC Monographs on the Evaluation of the Carcinogenic Risk of Chemicals to Humans. Chemicals and Industrial Processes Associated with Cancer in Humans, IARC Monograph Supplement 1. Lyon, France. September 1979.

†The last two IARC categories have been deleted because of their lack of relevance to EPA needs.

b. Limited evidence of carcinogenicity means that the data suggest a carcinogenic effect but are limited because: (a) the studies involve a single species, strain, or experiment; or (b) the experiments are restricted by inadequate dosage levels, inadequate duration of exposure to the agent, inadequate period of follow-up, poor survival, too few animals, or inadequate reporting; or (c) the neoplasms produced often occur spontaneously or are difficult to classify as malignant by histological criteria alone (e.g., lung and liver tumours in mice).

c. Inadequate evidence indicates that because of major qualitative or quantitative limitations, the studies cannot be interpreted as showing either the presence or absence of a carcinogenic effect.

8.1.2 Assessment of evidence for carcinogenicity from human studies

Evidence of carcinogenicity from human studies comes from three main sources:

1. Case reports of individual cancer patients who were exposed to the chemical or process.
2. Descriptive epidemiological studies in which the incidence of cancer in human populations was found to vary spatially or temporally with exposure to the agents.

DRAFT
DO NOT QUOTE OR
CITE
JUN 21 1982

3. Analytical epidemiological (case-control and cohort) studies in which individual exposure to the chemical or group of chemicals was found to be associated with an increased risk of cancer.

Three criteria must be met for a causal association to be inferred between exposure and human cancer:

1. There is no identified bias which could explain the association.
2. The possibility of confounding has been considered and ruled out as explaining the association.
3. The association is unlikely to be due to chance.

In general, although a single study may be indicative of a cause-effect relationship, confidence in inferring a causal association is increased when several independent studies are concordant in showing the association, when the association is strong, when there is a dose-response relationship, or when a reduction in exposure is followed by a reduction in the incidence of cancer.

The degree of evidence for carcinogenicity in human studies is categorized as:

a. *Sufficient evidence* of carcinogenicity indicates a causal assocation between exposure and human cancer.

b. *Limited evidence* of carcinogenicity indicates a possible carcinogenic effect in humans, although the data are not sufficient to demonstrate a causal association.

c. *Inadequate evidence* of carcinogenicity indicates that the data are qualitatively or quantitatively insufficient to allow any conclusion regarding carcinogenicity for humans.

DO NOT QUOTE OR
CITE
JUN 2 1 1982

Dividing lines are by no means firmly drawn between sufficient evidence and limited evidence from animal studies and between inadequate evidence and limited evidence from both human and animal studies.

B.1.3 Evaluation of the carcinogenic risk to humans

Presently, no objective criteria exist to interpret the animal data directly in terms of human risk. In the absence of sufficient evidence from human studies, evaluation of the carcinogenic risk to humans is based on consideration of both the epidemiological and experimental evidence. The quality of evidence discussed in B. 1.1 and B.1.2 is used by IARC to place the chemical into categories.

The chemical, groups of chemicals, or industrial process is placed into one of three groups:

Group 1

The chemical, group of chemicals, or industrial process is carcinogenic for humans. This category is used only when there was sufficient evidence to support a causal association between the exposure and cancer.

Group 2

The chemical or group of chemicals is probably carcinogenic for humans. This category includes chemicals for which the evidence of human carcinogenicity is almost 'sufficient' as well as chemicals for which it is only suggestive. To reflect this range, this category is divided into higher (group A) or lower (group B) degrees of evidence. The data from experimental

DRAFT
DO NOT QUOTE OR
CITE
JUN 21 1982

animal studies play an important role in assigning chemicals to category 2, and particularly to those in group B.

Group 3*

The chemical or group of chemicals is possibly carcinogenic for humans.

C. Quantitative Cancer Risk Estimation with Respect to Mutagenicity

The linear non-threshold extrapolation model has had extensive use in quantitative risk estimation beginning in the field of ionizing radiation and extending to chemical carcinogens. The rationale for the use of the linear non-threshold dose-response extrapolation model depends heavily on the mutagenicity of carcinogens. The biological justification for its use lies in the correlation between carcinogenesis and mutagenesis, the commonality of DNA damage for carcinogens and mutagens, the quantal nature of the interactions of chemicals with DNA, and the linear nature of the dose-response relationships for the induction of gene mutations, particularly with organisms such as bacteria, in which the induced mutation frequencies have been determined at lower exposure levels than in other organisms. From a theoretical standpoint, the multistage mathematical model for carcinogenesis has considerable biological plausibility, and linearity at low dose levels is a part of this model.

---

*The original IARC wording is as follows: "The chemical or group of chemicals cannot be classified as to its carcinogenicity for humans." Since agents in this category might or might not be carcinogenic for humans, the description "possibly carcinogenic for humans" is considered more appropriate, particularly since agents in this category might have "limited" evidence which is almost "sufficient."

DO NOT QUOTE OR
CITE
JUN 2 1 1982

In the absence of the induction of gene mutations, the use of the linear non-threshold dose-response model becomes less plausible. Many mathematical extrapolation models fit most tumor data in the range of experimentally observed responses but give widely divergent estimates of risk at the low doses generally encountered with environmental exposure, where it is not possible to obtain direct experimental or epidemiological dose-response relationships. The selection of a particular mathematical extrapolation model requires some acceptance of a mechanism of carcinogenic action. The plausibility of the linear non-threshold extrapolation model depends heavily on acceptance of the somatic mutation theory of cancer. We currently do not know enough about the mechanism of action of non-mutagenic carcinogens to plausibly extrapolate dose-response relationships for such agents to low levels of exposure.

We are therefore proposing, in principle, for apparently non-mutagenic carcinogens, to use the conventional toxicologic approach to defining exposure limits in terms of the no-observed-effect-level (NOEL) of response together with an uncertainty factor. However, in practice, since the evidence for mutagenicity is frequently not decisive, it may be appropriate to use both the linear non-threshold extrapolation model and the conventional toxicological approach together with guidance as to the relative weights to be given to each. This is the approach which is proposed for water quality criteria in Section D.

In Section C.1 we describe the conventional toxicological approach. Section C.2 proposes the criteria for evaluating chemical substances according to mutagenicity.

DRAFT
DO NOT QUOTE OR
CITE
JUN 21 1982

C.1 Conventional Toxicological Approach for Non-Mutagenic Carcinogens

The conventional toxicological approach to setting exposure limits is to select the highest dose that does not produce a response in test animals, and then to adjust this dose downward by dividing it by an uncertainty factor.

We propose to use the conventional toxicological approach for non-mutagenic carcinogens with an added refinement of making use of all the available data in a consistent fashion. This modification involves the use of the multistage extrapolation model to estimate the dose corresponding to a 10% response. The procedure has the advantage of standardizing the response level to which the uncertainty factor is applied. It is particularly appropriate when the no-observed-effect level is absent, as is often the case with NTP-type carcinogenesis bioassays that involve the use of maximum and half-maximum tolerated doses where both doses show tumorigenic responses. The 10% response level is a reasonable one because it is in the domain of the minimal level of response that can be observed in well-conducted bioassays. The extrapolated dose at the 10% response level is relatively insensitive to the particular mathematical model that is employed to determine it. The multistage model is recommended because it has had extensive use and has some biological rationale. The extrapolation can be done on the basis of a maximum likelihood estimate (MLE) or an upper confidence limit. In line with conventional practice, the proposed approach would use the maximum likelihood estimate and a dose conversion from animals to humans on a body weight basis rather than by surface area.

DRAFT
DO NOT QUOTE OR
CITE
JUN 2 1 1982

primary concern because there is evidence that gene mutations caused by chemical agents that react with DNA follow a linear non-threshold mechanism; such evidence does not exist for chromosome mutations.

As with carcinogenicity, a weight-of-evidence approach is used for evaluating genotoxicity; the evaluations are described under the following categories: adequate, inconclusive, negative, and inadequate.

Adequate evidence involves positive responses in any two appropriately conducted different gene mutation systems, one of which is a eucaryotic system, or, by itself, a positive response in a whole mammal gene mutation test. It should be noted that the generally accepted definition of mutation is a relatively permanent change in hereditary material involving either a fundamental change in genes or a physical change in chromosome structure or number. However, only point mutation is considered as positive, whereas chromosomal mutation is not considered as positive for the reason discussed above concerning linear non-threshold mechanisms. Chromosome mutations and primary DNA damage (e.g., sister chromatid exchanges, unscheduled DNA synthesis, mitotic recombinations) are considered as supportive evidence for the ability of a chemical substance to cause gene mutations, since chemicals that cause these effects may also cause gene mutations.

Inconclusive evidence exists where definitive conclusions about mutagenicity cannot be made. In some cases it may be possible to indicate whether the evidence tends toward being positive or negative.

The choice of the uncertainty factor is somewhat arbitrary. A factor of 1,000 is recommended consisting of factors of 10 each for 1) the possibly greater sensitivity of humans in general compared to animals in general; 2) the sensitivity of the most susceptible human compared to the average human; and 3) an additional factor of 10 because of the general irreversibility and lethality of the carcinogenic response.

When carcinogenesis data are available in humans, the first uncertainty factor is considered to be a safety factor of 10 based on the greater certainty that the agent is carcinogenic for humans. Thus, in both humans and animals, the uncertainty factor is 1,000.

Given our current uncertainty about how to estimate cancer risk at low levels of exposure to non-mutagenic carcinogens, the proposed conventional toxicological approach does not necessarily imply the existence of a cancer threshold level below which exposures are completely safe. Hence, wherever possible, the formulation of exposure limits should tend toward the lowest feasible levels.

C.2 Criteria for Evaluating Chemical Substances with Respect to Their Ability to Cause Gene Mutations

Evaluating the ability of chemicals to cause gene mutations will assist in deciding whether to use a linear non-threshold extrapolation model to estimate cancer risk. The rationale for this approach, described above in Section C, is based on the somatic mutation theory for carcinogenesis. Somatic mutations include gene mutations as well as chromosome mutations. Gene mutations are of

Inadequate evidence exists when the evidence is insufficient as a basis for the evaluation of mutagenicity.

Negative mutagenicity is defined operationally as negative responses that are obtained in an adequate number of test systems capable of detecting gene mutations, chromosomal aberrations, and primary DNA damage. An adequate number and combination of test systems may vary from chemical to chemical and depends on many factors such as physical-chemical properties, structure-activity relationships, and toxicity of the chemical to the test organisms. As a consequence, professional scientific judgment is required on a case by case basis to determine the number and types of test systems necessary to classify a chemical as being non-mutagenic.

D. Application to Water Quality Criteria of Additional Guidance for the Health Assessment of Suspect Carcinogens

The Consent Decree Water Quality Criteria (44 FR 15974, March 15, 1979 and 45 FR 79347, Nov. 28, 19 were based on the 1976 guidelines for the assessment of suspect carcinogens and used the linearized multistage extrapolation model, regardless of the evidence for or against mutagenicity, to establish the concentration that would be associated with a maximum excess cancer risk of 10^{-5}. In order to incorporate evidence for mutagenicity, it is proposed here that both the linear non-threshold and the conventional toxicological approaches be used to provide a range of water quality criteria values. It should be recognized that the conventional toxicological approach

DRAFT
DO NOT QUOTE OR
CITE
JUN 21 1982

specifies an exposure limit; the linear non-threshold extrapolation model provides the relationship between risk and exposure, and requires the selection of a risk value in order to define an exposure limit. It is proposed that the range of values for the water quality criteria would involve a lower limit, which would be the concentration associated with an excess lifetime cancer risk of 10^{-5}, and an upper-limit, which would be the concentration specified by the conventional toxicological method.

The weight-of-evidence for or against mutagenicity as well as the weight-of-evidence for carcinogenicity would provide the basis for the water quality criteria guidance as shown in Table 1. Adequate evidence of mutagenicity and sufficient evidence of carcinogenicity would tend to call for the use of the linear method. Sufficient human or animal evidence for carcinogenicity and negative evidence for mutagenicity would tend to call for the use of the conventional toxicological method as would limited evidence for carcinogenicity together with inadequate or inconclusive evidence for mutagenicity. Inadequate or inconclusive mutagenicity data, together with sufficient human or animal carcinogenicity evidence, or adequate evidence in mutagenicity with limited evidence for carcinogenicity, would tend to call for a water quality criterion in the domain of the average of the criteria determined by the linear and the conventional toxicological methods. The midrange would be the geometric mean, that is, the square root of the product of the bounding concentrations of the water quality criteria range, since this places the midrange equidistant from the extremes on a proportional basis. Such guidance, together with the usual considerations that go into regulatory

decision-making, would determine where in the range the actual water quality standards would be set.

Table 2 illustrates the above approach to water quality criteria guidance for selected compounds. The carcinogenicity and mutagenicity categorizations are indicated for each compound. The water quality criteria concentrations listed in column (a) were obtained using the "linearized" multistage model with an upper 95% confidence limit for the linear non-threshold extrapolation and a surface area correction. Water quality criteria are presented in column (b) which were calculated by the proposed conventional toxicological approach using the multistage model to obtain the MLE of the 10% level of response, an uncertainty factor of 1,000, and an animal-to-man conversion on the basis of body weight. It can be seen in column (c) that for these chemicals the proposed NOEL approach results in water quality criteria concentrations that range from about 10 to 369 times greater than those obtained using the linear method.

The guidance given in column (e) is based on the criteria given above. In practice, the guidance would need to be formulated by a group of experts with due consideration of all of the available evidence. The guidance toward the midrange with many of these compounds reflects the fact that few suspect carcinogens have been tested adequately for mutagenicity. In some cases, it might be appropriate to defer guidance if additional information can be obtained in a reasonable time particularly where the evidence for mutagenicity is inadequate or inconclusive. The midrange values, calculated as geometric

averages, are given in column (d). As with the values for the range of water quality criteria given in columns (a) and (b), the midrange is not meant as a hard figure but as a target to be sought. Water quality criteria based on the most sensitive non-cancer toxic response is given in column (f) as a limit not to be exceeded by the water quality criteria based on cancer.

E. Options for Alternative Approaches to the Formulation of Water Quality Criteria

1. The 95% upper confidence limit could be used to estimate the 10% response level instead of the maximum likelihood estimate (MLE). It would be a somewhat more stable value than the MLE and would reward good experimentation. The approach would generally lower the water quality criteria by a factor of 2 to 3. However, an upper-limit approach to the conventional toxicologic method, on the grounds of consistency, might call for the adoption of other conservative approaches which in the aggregate could amount to a factor of 36.

2. The dose conversion could be done on a surface area rather than a weight basis. Although more scientifically defensible for some pharmacological effects, it is not clear that this would be true for carcinogens. The approach would result in lower water quality limits by a factor of 6 or 12 for studies done on rats or mice, respectively. Use of the surface area conversion is not the conventional toxicologic approach.

CITE
JUN 21 1982

3. A series of graded uncertainty factors could be established on the basis of strength of evidence for carcinogenicity and mutagenicity that would specify a single water quality criterion number rather than a range with guidance. This would avoid the possible difficulty that the proposed approach could result in different water quality criteria in different states. However, graded uncertainty factors associated with specified strength of evidence would be a somewhat arbitrary scheme.

4. The linear extrapolation could be extended down to risk levels of 10^{-6} or 10^{-7} instead of 10^{-5} to establish the lower range of the water quality criteria concentrations. This would conform to the currently promulgated water quality criteria, where such options are offered, and would be simple to include in the proposed approach. However, it might be widely regarded as excessively restrictive.

5. The midrange guidance could be done on an arithmetic basis rather than on a geometric basis; this would be a far less conservative approach since the resulting level would be relatively close to the upper concentration range, i.e., 1/2 the upper value. The midrange guidance is used where it is uncertain whether the dose-response is linear or curvilinear; i.e., where the risk drops very rapidly with decreasing dose. Where the concentration range is, for example, 100, the range of risk would also be 100 if the response were really linear. The use of the arithmetic average would thus represent a dose

DRAFT
DO NOT QUOTE OR
CITE
JUN 21 1982

reduction from the upper-limit of only a factor of 2 and would thus constitute an endorsement of the curvilinear dose-response when the data do not support such a position. A geometric average, which in this example would be 10 times larger than the lower-limit and 10 times smaller than the upper-limit, would be a more balanced approach.

6. Limited carcinogenicity data with inadequate or inconclusive evidence for mutagenicity could call for a guidance toward the midrange instead of toward of the upper concentration limit. The double uncertainty about whether an agent is really carcinogenic and mutagenic is the basis for the proposed approach, but the midrange guidance might be more appropriate as one which errs on the side of protection.

Waterborne Carcinogens: A Regulator's View

VICTOR J. KIMM, ARNOLD M. KUZMACK,
and DAVID W. SCHNARE

COST-BENEFIT analysis is useful in the regulatory decision process because it helps identify many anticipated effects of regulations and establish program priorities and the order in which potential regulatory actions should be followed. However, there are serious problems in quantifying various factors in such analysis, especially those related to health effects. The widespread use of cost-benefit analysis may not lead to improved decisionmaking.

Risk of death, injury, or serious illness is an ever-present aspect of daily living. Indeed, we all take measurable risks for benefits that are small or even frivolous. Every time we drive to another city instead of flying, or every time we get impatient while trying to make a left turn and do not wait until all oncoming cars have passed, we are showing that we place a finite value on our own lives. And though we may take those risks voluntarily, they are involuntary for the friends and family members riding with us.

In the broad range of societal activities called "regulation," implicit valuation of human life and the resulting limitation on what we as a society are willing to pay to save lives are commonplace. No regulatory agency would, for example, seriously consider requiring the installation of a technically perfect air bag system costing $10,000 for each car, even if the law explicitly required the maximum feasible protection. No government regulatory agency is trying to achieve a "zero-risk society." The

The views expressed in this paper are those of the authors and do not necessarily represent the official position of the U.S. Environmental Protection Agency.

Delaney clause in the 1958 Food Additive Amendments, for example, is one of the few cases in which Congress itself balanced risk and benefit rather than delegating this judgment to a regulatory agency.[1] Congress concluded (whether correctly or not) that no food additive had sufficient benefits to justify any carcinogenic risk.

Such balancing is not new. When the Food and Drug Administration set allowable levels for mercury in fish, it had to make a whole series of assumptions involving such things as the level of fish consumption, the reliability of toxicity studies, the proportion of the mercury that is in the more toxic organic forms, and the magnitude of the safety factor. There would be a substantial difference in the final mercury level, for example, if it were based on the 90th percentile of fish consumption or on the 99.9th percentile. Thus, depending on these and other similar assumptions, the Food and Drug Administration could be more or less conservative, more or less stringent in the level eventually set. The point is that judgments about the costs and benefits of alternative mercury levels are buried in the choices that were made. So what is new is not that the balancing of risks and benefits is going on, but that it is becoming more explicit, particularly in the regulation of carcinogens. Since we assume that there is no safe level for a carcinogen, we can no longer pretend that our standards are safe levels—that is, levels at which no risk would occur.

As society grapples with the problems of regulation of carcinogens, regulatory agencies are being urged to quantify risks and benefits and to conduct cost-benefit analyses. President Carter's Executive Order 12044 encouraged the performance of such analyses, and President Reagan's executive order goes considerably further in this direction.[2] A variety of regulatory reform bills have been introduced in Congress that would require them with varying degrees of strictness. Some of these proposals seem to be based on the naive notion that the agencies do not balance risks and benefits and should, and that doing so would clearly show that many regulations are unjustified. A more sophisticated version of this argument maintains that the quality of decisionmaking would be vastly improved if agencies' implicit judgments about risks and benefits were made explicit and subjected to as much rigorous and quantitative analysis as possible. The regulatory agencies certainly have problems and should take advantage of whatever will enable them to make correct choices. But the

Environmental Protection Agency's experience with the drinking water regulations leads to serious doubts that formal risk-benefit or cost-benefit analyses will actually improve decisionmaking.

To understand why, it is important to understand how carcinogens are regulated. All the federal regulatory agencies have made the policy judgment to treat carcinogens as though they have nonthreshold effects—that is, as if any exposure to such a substance, no matter how small, causes a small but nonzero probability of a cancer that could result in death. This is a policy judgment that has been developed over a long period, not a statement of scientifically proven fact. The basis of the judgment can be summarized briefly.

First, the existence of a threshold cannot be experimentally proven. Suppose that at some dose level, an experiment fails to show any positive response. Empirically the possibility cannot be ruled out that an experiment with a much larger sample size would have shown an effect. (Even if the larger experiment were then performed, the same argument could be applied.) Although this holds true for all toxicants, carcinogens and certain other categories of toxicants are treated differently.

For conventional toxicants a threshold is assumed, and the experimental data are used to estimate it, usually by taking the lowest no-effect dose and applying a series of safety factors that have been developed in the folklore of toxicology to allow for the genetic variability of the population and other factors. A threshold is assumed because the kinds of toxic effects in question are those in which a substantial number of cells must be functionally impaired to produce an adverse effect on the whole organism. For example, most of us could have a few liver cells damaged with no ill effects, since proliferation of new cells would compensate for the loss. It is only when a large portion of the cells in a particular organ are affected that the body is unable to compensate and a toxic effect occurs. In chemical carcinogenesis, on the other hand, a complex and poorly understood process occurs in a single cell and transforms that cell into a tumor cell that will multiply uncontrollably and eventually kill the host. However the chemical carcinogen participates in that process, it is likely that a single molecule or only a few molecules are involved. For that molecule to reach the cell's vulnerable point, another complex series of metabolic transformation and transport (pathways) must occur. That process may not be linear in dose, of course, and may include a large number of minor, virtually immeasurable, pathways along with the major pathways. In only a few cases is anything known about the major pathways, and it is impossible to reliably link knowledge about metabolism to the carcinogenic process.

For these reasons, the federal agencies involved in regulating carcinogens have reached the policy judgment to treat all carcinogens as though there were no threshold to their action. This means that when there is evidence that a substance causes cancer at high doses, it should be assumed that there is some risk at low doses as well. This assumption is consistent with what is known about carcinogenesis, but cannot be tested scientifically. This does not mean, however, that the substance should be banned or otherwise regulated. The decision about whether to regulate depends on a balancing of risks against benefits.

Evidence of Risk

Three kinds of evidence typically indicate that a substance is a carcinogen. First, in a few cases, there is clear-cut human evidence. This can be expected only when there are well-defined highly exposed and unexposed groups in the population, as with those who smoke and those who are exposed to some occupational chemicals, or when the tumors involved are of such a rare type that any clustering is strong evidence, as with liver angiosarcoma caused by vinyl chloride. While such evidence should obviously be exploited when it exists, it is likely to be available only in these special circumstances.

Second, there may be ambiguous human evidence in a few cases. When the exposures are low, as is usually the case with environmental contaminants, the magnitude of the effects is also likely to be small and therefore difficult to detect in an epidemiological study. When a positive association is observed, it is difficult to be certain whether it is caused by the substance or substances under consideration or by some other unrelated factor that happens to be correlated with the substance or by possible confounding factors. In the case of organic contaminants in drinking water, most of the dozen epidemiological studies that have been done demonstrate an association between cancer rates and some aspect of drinking water. Yet such association does not prove that chemicals in drinking water cause cancer but rather adds weight to the hypothesis of an effect on cancer rates.

Finally, in most cases, we will be forced to rely on animal experiments. Unlike the second type of epidemiological study, most animal studies generally show that the effects observed are in fact caused by the chemicals being studied. But these studies have their own problems. The two most obvious are extrapolation from animals to humans and from high to low doses, the latter problem being shared with most occupational epidemiology studies. In any case, the federal regulatory agencies have judged that substances that cause cancer in animals present a risk of cancer to humans at low doses. This consensus has been expressed in the National Academy of Sciences' *Drinking Water and Health,* a report produced under a mandate of the Safe Drinking Water Act.[3]

This consensus reflects a social decision that has been made in the face of scientific uncertainty. In most cases concerning environmental exposures to carcinogens, science can neither prove nor disprove that a risk exists, although the judgment that a risk does exist at low doses is consistent with what is known about carcinogenesis. Furthermore, since epidemiology is usually not sensitive enough to detect possible effects of carcinogens, it will also be too insensitive to verify that a reduction of cancer risk has in fact occurred after regulatory action. Thus, not only do we not know for sure whether regulatory action will actually reduce the incidence of cancer (and, of course, nobody knows for sure that they will not), but we will also probably never know from direct empirical evidence. The only hope of reaching greater certainty in this area is through greater understanding of the fundamental mechanisms of carcinogenesis and the metabolism and transport of chemicals in the body.

Risk Extrapolation

Until a few years ago substances that caused cancer in animals were regulated without attempts to measure the impact of the regulations. The balancing of risks and benefits required under the pesticide law, for example, was largely a matter of determining whether substitutes existed for particular uses: if a substitute was available, it was generally assumed that the benefits of use were smaller than the risks.[4] Air and water pollution control requirements were based on use of the best available control technology.

[4] Federal Insecticide, Fungicide, and Rodenticide Act of 1972 (86 Stat. 973).

Recently, however, interest has increased among regulatory agencies in the use of mathematical risk extrapolation models to derive quantitative estimates of the risks posed by exposure to carcinogens. This interest has evolved from several sources. Since the agencies' resources are limited and the regulatory process arduous, some way was needed to set priorities, to determine which of the thousands of potential regulatory targets should be high on the list. There was also concern that action might be taken in cases where the exposures were so small that the effects would be insignificant when evaluated. There was a feeling in some of the agencies that decisionmakers should have some estimate of the magnitude of the risks they were attempting to reduce, no matter how crude.

It is probably fair to say that the Environmental Protection Agency took the lead, among regulatory agencies, in applying risk extrapolation models to actual regulatory decisionmaking involving chemical carcinogens. Some of the models had been used for decades in the regulation of exposure to ionizing radiation, and the Food and Drug Administration had made limited use of them in regulating food contaminants. The process was tried out as part of the rulemaking on air emissions of vinyl chloride and has been institutionalized in the agency through establishment of the Carcinogen Assessment Group in 1976. Other agencies have adopted risk extrapolation models to varying degrees, and a recent decision of the Supreme Court, though ambiguous, appears to require some form of quantitative estimate of risk levels as a prerequisite for regulation under the Occupational Safety and Health Act of 1970.[5] The federal government's ambivalance toward these methods is indicated by the interdepartmental Regulatory Council's official government-wide policy statement, "The Regulation of Chemical Carcinogens," which says, in part, the following:

> After it has been determined that a chemical substance is likely to be carcinogenic, the next step in regulatory decision-making is to assess the risk that people face of developing cancer from their exposure to the substance. . . .
>
> The form, methodology, and elaborateness of the assessment may vary substantially. . . .
>
> Except where a statute, as in the case with the Clean Water Act, explicitly indicated which substances are to be controlled and how, every regulatory proposal will be accompanied by some form of risk assessment which includes,

[5] *Industrial Union Department, AFL-CIO* v. *American Petroleum Institute*, 448 U.S. 607, 100 S.Ct. 2844, 48 U.S.L.W. 5022 (1980). The statutory citation for the Occupational Safety and Health Act of 1970 is 84 Stat. 1590.

> at a minimum, an analysis of the substance's carcinogenicity and a determination that people are likely to be exposed to the substance. . . .
>
> Where the available data are scientifically adequate to support them, quantitative risk estimates can provide useful information for proposed regulatory decisions. . . . However, quantitative risk estimates are not yet sufficiently developed to be regarded as more than rough indicators of the level of human risks.[6]

Thus, the Regulatory Council has taken the position of encouraging the agencies to use risk extrapolations but is not willing to require their use. One of the concerns about the use of extrapolation models is based on the limitations of the models themselves. Those that are usually used to assess risk fall into two groups. The first, of which the Bryan-Mantel procedure is the best known,[7] is based on the assumption that the fraction of the population responding at a range of doses follows a log-normal function; the underlying assumption is that the susceptibility of individuals in the population is log-normally distributed. This leads to a mathematical formulation that never reaches zero as dose approaches zero but that falls off much faster than linearly. The second group of models, which includes the one-hit, multiple-hit, and linear no-threshold models, all have linear dose-response curves at low doses.[8] These models are based on a conception of carcinogenesis in which infinitesimal increments of doses randomly cause changes in target cells (for example, molecules that bind to DNA), some portion of which will transform the cell into a tumor cell.

Both sets of models are rich enough mathematically to fit the experimental data as well as anyone could ask (at least when the data are monotonic). Thus, one cannot distinguish between them empirically on the basis of fit. And for both of them, doses are typically extrapolated by factors of perhaps one thousand to one million. With such a range of extrapolation, the scientific certainty of the results is unclear at best. These extrapolations fall far short of being predictions based on a chain of logic whose steps are empirically verified. Since present knowledge does not rule out the possibility that a dose threshold may in fact exist, particular environmental carcinogens may actually pose zero risk. It is also not difficult to develop a model in which the response would be higher than that predicted by the one-hit model.

[6] Regulatory Council, "Regulation of Chemical Carcinogens" (September 1979), pp. 8–10.

[7] Nathan Mantel and W. Ray Bryan, "Safety Testing of Carcinogens," *Journal of the National Cancer Institute*, vol. 27 (August 1961), pp. 455–70.

[8] P. Armitage and R. Doll, "Stochastic Models of Carcinogenesis," in *Proceedings of the 4th Berkeley Symposium on Mathematical Statistics and Probability*, vol. 4 (University of California Press, 1961), p. 19; and K. S. Crump and others, "Fundamental Carcinogenic Processes and Their Implications for Low Dose Risk Assessment," *Cancer Research*, vol. 36 (September 1976), pp. 2973–79.

In spite of the models' serious shortcomings, there is a need, perceived by both the agencies and their critics, for some kind of answer to the question, "What are we buying with this regulation?" In response to this need, there has been a tendency to choose as a working model the linear no-threshold model and its variants. It has a preferred place both in the Environmental Protection Agency guidelines issued in 1976[9] and in the Interagency Regulatory Liaison Group guidelines issued in 1979.[10] The reasons usually given for this choice are that the model is conservative and is consistent with what is known about the biological mechanism of cancer. By the term *conservative* people seem to mean that the model gives higher risk estimates than other models. So few usable data exist for low doses that no one really knows whether the linear model is in fact conservative. The linear or one-hit model is consistent with the theory of carcinogenesis as involving random binding to a cell's DNA, but it is not consistent with the other parts of scientific knowledge. In many cases, the substance that interacts with the DNA is not the same as what people swallow or breathe, but rather a metabolite of the contaminant found in the environment. Metabolites can be more or less toxic than the original compound. In fact, the way the body deals with a particular carcinogen is likely to consist of a complex sequence of metabolites and competing pathways, one or more of which may be involved in carcinogenesis. These various processes may be more or less active at different doses, so the effects may not be linear with dose.

Probably the best thing that can be said about the linear one-hit model is that it is the simplest index of carcinogenic risk scientists have been able to develop. If compound A produces tumors in 50 percent of the experimental animals at a given dose and compound B produces the same response at 1/100 of that dose, and if both are present in the environment at the same levels, then we should probably be one hundred times as worried about compound B as about A. This logic is basically what the linear model generates. Unfortunately, things are not quite that simple.

[9] U.S. Environmental Protection Agency, "Interim Procedures and Guidelines for Health Risk and Economic Impact Assessments of Suspected Carcinogens," *Federal Register,* vol. 41 (May 25, 1976), pp. 21402–03.

[10] Interagency Regulatory Liaison Group, "Scientific Bases for Identification of Potential Carcinogens and Estimation of Risks," *Federal Register,* vol. 44 (July 6, 1979), pt. 3, pp. 39859–79.

Many questions or methodological choices have to be resolved before applying the linear model or one of its variants. These questions include the following:

1. How can animal doses in a laboratory experiment be converted to equivalent human doses? The most popular solutions are to scale the conversion either on body weight or on surface area.

2. How can the data from different experiments and different species-sex-dose groups in a single experiment be combined? For example, the most sensitive single point in the data could be used or some method of curve fitting to all the data could be adopted.

3. Given the possibility that the observed effect may not be caused by the substance in question, should data from human epidemiological studies be used, and if so, how?

4. How can the statistical uncertainty in the animal tests resulting from the limited sample sizes used be accounted for?

5. How can intermittent dosing schedules—for example, doses given five rather than seven days a week—be accounted for?

6. How can data from experiments in which the dosing does not continue for the animals' lifetime be incorporated?

7. How can data from experiments in which animals are killed before their natural deaths be incorporated?

8. How can differing mortality in various experimental groups be incorporated?

9. How should benign tumors or other lesions that, in the opinion of some experts, would have been likely to develop into malignant tumors in the future be dealt with?

10. How can data on the time of tumor occurrence be incorporated?

11. How should situations in which a substance appears to cause tumors at more than one site be dealt with?

12. How can the fact that humans are frequently exposed to substances in utero and experimental animals usually are not be accounted for?

This list is probably not exhaustive, and legitimate differences of opinion exist on all or most of the points. The impact of these questions is significant. For example, the first on the list, conversion from animal to human equivalent doses, changes the result by a factor of thirteen when extrapolating from data on mice. The range of outcomes that would result from reasonable solutions to each of these problems could easily be greater than a factor of one thousand. This is not just an abstract possibility, as two examples will show.

The National Academy of Sciences produced two reports within a year of each other that use the same experimental data and contain risk extrapolations for chloroform using the one-hit model. In one report the lifetime cancer risk was estimated at 2 times 10^{-7} for each microgram of chloroform consumed per day.[11] In the second report the risk was estimated at 22 times 10^{-7} for every microgram of chloroform consumed per day.[12] These estimates differ by a factor of eleven. A second example is the results of a comparison the Environmental Protection Agency made recently between the risk extrapolations made by the National Academy of Sciences for a number of different carcinogens and those made independently by the agency's Carcinogen Assessment Group for some of the same substances. Some comparisons were very close, but others differed by factors as large as one hundred in both directions.

The magnitude of these ranges is important: it is hard to imagine many cost-benefit analyses whose conclusions would not be changed if one side of the balance were multiplied or divided by one hundred or one thousand. The situation is even more precarious if a true risk of zero is considered possible, since the possibility cannot be excluded that a threshold may actually exist, or that the risk could be larger than calculated if the linear model is not conservative enough or if synergistic effects occur with other environmental contaminants.

This range of uncertainty is not as serious if one requires less from the models—that is, not an absolute estimate of the number of cancer cases anticipated but only a comparative index for setting priorities, based on expected carcinogenic potency, and for getting a very rough idea of a problem's seriousness. For these purposes, it probably does not matter much which way the questions listed above are resolved. What is important is that a single methodology be generally accepted, so that comparisons can be made among cases.

The Trihalomethane Regulation

It is clear from this discussion that estimating the health benefits of carcinogen regulations is fraught with uncertainty. Further difficulties in applying cost-benefit or risk-benefit analysis can be illustrated by the example of the regulation of organic contaminants in drinking water.

---

[11] National Academy of Sciences, Panel on Low Molecular Weight Halogenated Hydrocarbon of the Coordinating Committee for Scientific and Technical Assessments of Environmental Pollutants of the National Research Council, *Nonfluorinated Halomethanes in the Environment* (NAS, 1978), p. 197.

[12] National Academy of Sciences, *Drinking Water and Health*, p. 716.

Recently promulgated was a regulation for trihalomethanes, which set a maximum contaminant level of 100 micrograms per liter, applicable to all public water systems serving ten thousand or more people.[13] Trihalomethanes are a group of compounds, of which chloroform is the most common, which form during water treatment as a by-product of disinfection with chlorine. Varying amounts of these compounds, therefore, are found in all public water systems that chlorinate their water and are most concentrated in systems whose raw water contains relatively large amounts of naturally occurring organic matter.

The Environmental Protection Agency performed a cost-benefit analysis for this regulation. The agency had to assume that (1) the trihalomethane levels found in a series of nonrandom surveys were representative of the entire nation; (2) specific treatment technologies would be chosen by systems to comply with alternative standards under various conditions and with the trihalomethane standard set at different levels; (3) the trihalomethanes other than chloroform had the same carcinogenic potency as chloroform; and (4) other disinfection by-products pose no health risks. The agency also had to pick a risk extrapolation method.

There are problems with these assumptions, but the limitations in the available data forced the agency to make them. Under these assumptions, the agency made a point estimate of the number of cancer cases avoided as a result of the promulgated regulation—322 cases per year. The costs of compliance had been estimated at $18.7 million per year. The agency was thus able to derive an average cost per case avoided of about $60,000 and a marginal cost per case avoided (relative to the maximum contaminant level) of about $200,000. It is unclear what significance should be ascribed to these figures. It is our impression that the trihalomethane regulation compares favorably in terms of cost per life saved to other regulations for which similar computations have been made, but it is not known if this has any meaning without determining whether the assumptions and methodologies are consistent.

What is perhaps more interesting is that the information captured by this calculation does not include the considerations the agency wrestled with in its attempt to balance costs and benefits. For example, there was concern that the regulation of trihalomethanes not interfere with adequate disinfection of water, particularly in smaller systems where unsophisticated operators might try to reduce trihalomethane levels by reducing the amount of chlorination. The agency therefore proposed that the standard not be applied to systems serving populations below seventy-five thousand, a position modified in the final regulation to include phased implementation down to systems serving ten thousand people. Similarly, it was the fear of making too great a change in a process closely intertwined with disinfection that led the agency to set the standard as high as 100 micrograms per liter, although the agency believes that much lower levels ultimately will be attainable.

---

[13] Environmental Protection Agency, "National Interim Primary Drinking Water Regulations: Control of Trihalomethanes in Drinking Water," *Federal Register*, vol. 44 (November 29, 1979), pt. 3, pp. 68624–707.

The agency also wrestled with another aspect of the trihalomethane problem. Little is known about the chemistry and toxicology of the byproducts of disinfectants other than chlorine whose use would be stimulated by a trihalomethane regulation. Since any disinfectant is a biologically active substance that kills bacteria, this is an area of serious concern. The agency has attempted to deal with the immediate problem by writing provisions into the regulation that limit the addition of other disinfectants to water with high disinfectant demand. The agency has also initiated a series of research programs to gather basic data in this area. Ultimately, a limitation on disinfectant demand may be implemented that would force systems to clean up the water before adding disinfectants. The important point is that these are considerations that do not easily fit into the cost-benefit analysis, yet they are the ones that are most bothersome. It is almost as though cost-benefit analysis, at least in this case, helps deal with the easy part of the problem but does not help with the hard part.

Because cost-benefit analysis requires the inclusion of *all* costs and benefits, the Environmental Protection Agency's analysis is incomplete. The agency has not been able to quantify some of the most important aspects of the trihalomethane regulation. However, we believe that this experience is typical of attempts to use methods of cost-benefit analysis on actual problems in the field of health and environmental regulation.

In the second part of the proposed organics regulation—a treatment technique requirement for granular activated carbon or an equivalent in large vulnerable water systems to remove synthetic organic chemicals—the agency was totally unsuccessful in capturing a significant part of the problem in the cost-benefit analysis framework. Many commentors on the regulation, including the U.S. Council on Wage and Price Stability, urged the agency to perform such an analysis.[14] The council presented its own attempt, which the agency does not think is valid; but the agency has not been able to come up with a valid approach. The problem is that no one knows what levels of which chemicals would be removed with granular activated carbon. There are many thousands of organic chemicals in drinking water. Already identified are over 700, which represent only 15 percent by weight of all organic matter found in drinking water.[15] Only a few have been tested for carcinogenicity in the usual animal tests. The agency has conducted several surveys of water from different systems and has found that the levels of measurable chemicals vary widely from system to system and even from day to day. It would therefore be difficult to derive a risk estimate based on this fragmentary occurrence data, even for those measurable chemicals that have been tested for carcinogenicity. The agency has not been able to think of any way to estimate the risk to public health posed by compounds that cannot be measured or that have not been tested for carcinogenicity. Nor do methodologies exist for dealing with the potential effects of human exposure to mixtures of carcinogens, including possible synergistic effects. Yet the value of granular activated carbon is that it removes a wide variety of these compounds from water. The agency has suggested that it makes sense to spend a nominal amount, less than ten dollars per family each year, to take advantage of a known technology that will remove a variety of organic contaminants. Yet neither the agency nor its critics have been able to develop a method of analysis that would help determine whether or not granular activated carbon is worth its costs.

Thus, the agency has not found cost-benefit analysis to be a powerful tool, at least for developing a regulatory strategy to deal with the presence of organic carcinogens in drinking water. The agency is concerned that little thought has been given to the results of inserting cost-benefit analysis into the adversary process of rulemaking. It is predictable that both (or all) sides will be able to introduce analyses that support their points of view. Each will then bring forward analysts, of equivalent credentials, who will argue among themselves about the superiority of their particular

[14] Ivy E. Broder, "Analysis of Proposed EPA Drinking Water Regulations" (U.S. Council on Wage and Price Stability, September 1978).

[15] National Academy of Sciences, *Drinking Water and Health*, pp. 489–92; and Environmental Protection Agency, Office of Water Supply, "Statement of Basis and Purpose for an Amendment to the National Interim Primary Drinking Water Regulation on a Treatment Technique for Synthetic Organic Chemicals" (January 1978), p. 1.

analyses in a language all their own. Incomprehensible analysis may then drive out understandable argument. This might be worth enduring if the issues being debated were central to the decision at hand. However, if the drinking water regulation's problems are at all typical (and we believe they are), the cost-benefit analyses are likely to capture only a small part of the problem and deflect attention from the rest. This will not contribute to better decisionmaking.

If cost-benefit analysis becomes a legal requirement, these difficulties will be multiplied. There will be a period of uncertainty until a body of case law is developed that will show what the courts consider an adequate analysis. This delay will benefit the opponents of any change in regulations. A great deal of energy and attention would probably then be focused on how well the analysis satisfies whatever criteria have developed. Given the limitations of cost-benefit analysis, this allocation of the limited resources of time and personnel does not seem to be warranted.

An alternative to cost-benefit analysis is the use of technology-based standards. This approach is most clearly exemplified in the provision of the Federal Water Pollution Control Act Amendments of 1972[16] that requires effluent limitations on water polluters based on the "best available technology." The use of the best available technology seems particularly attractive in the case of carcinogens. Since it is assumed that there is no safe level, it seems reasonable to reduce exposures as much as possible. But the technological approach does not preclude the necessity of balancing costs and benefits. It is always possible to spend more money to reduce exposures. Even if no more advanced technology is known, more of the old technology can always be used. So there is a considerable range of judgment as to what constitutes best available technology, and the degree of stringency chosen depends implicitly on the perceived magnitude of the risk.

Another approach to regulation is to continue balancing risks and benefits intuitively. With this approach, risk extrapolation models would be used when possible. Over time, regulators would develop a feeling for the ranges of risk that will have been judged socially acceptable in previous decisions and would aim for that range of risk unless there were reasons to be more or less stringent in a particular case. When possible, regulators could even calculate the marginal cost of each cancer case avoided and develop a feeling for what ranges have been judged socially acceptable in previous decisions. But we would be wary of overformalizing the approach. Ideally, each case would lead to a creative resolution of conflicting goals.

---

[16] 86 Stat. 816.

Another problem is that of communicating regulatory activities to the public. Ultimately, the success of any social enterprise in a democratic society depends on the informed support of the people. Yet many discount the reports of carcinogens in their environment and do not believe, for example, that smoking causes cancer; and others go to ridiculous lengths to avoid minuscule risks, such as avoiding products containing polyvinyl chloride for fear of getting liver cancer. Because the adversary process tempts people to either exaggerate or minimize risks, almost nobody understands that although the risks may or may not exist, it is rational to treat them as real; that any reduction in cancer rates is likely to be small but still worth achieving; and that probably no one will ever know the true impact of preventive action. Sooner or later, regulatory agencies will have to face the consequences of their failure to communicate.

Appendix: Net Benefits of Several Trihalomethane Levels

The Environmental Protection Agency published a final regulation to control trihalomethane levels on November 29, 1979.[17] The regulation imposes a maximum contaminant level allowing no more than 100 micrograms of trihalomethanes per liter of finished drinking water. The requirement for granular activated carbon filtration systems to remove all organics was not promulgated. While the trihalomethane standard was being developed, other potential levels were suggested. There was a vigorous discussion of the cost estimates of control technology, and many issues related to risk estimation were raised. Within this highly charged atmosphere, the agency was challenged to analyze the economic efficiency of the proposed standards. As already discussed, there are several practical difficulties associated with refined cost-benefit analysis. The following case study presents the basic methodology used to determine the net benefits of alternative levels for the trihalomethane standard and discusses the dramatic effect produced by changes in basic assumptions.

Benefits associated with control of trihalomethanes essentially consist of a reduction in the number of cancer cases that could be attributed to the contaminant. The National Academy of Sciences presents the general formula for estimating cases avoided in *Drinking Water and Health:*[18] annual number of cases avoided equals RVT/E, where R equals risk per microgram per liter, V equals liters per day consumption, T equals total (national) reduction in exposure (in micrograms), and E equals life expectancy.

---

[17] Environmental Protection Agency, "National Interim Primary Drinking Water Regulations."

Knowing the number of cases avoided allows for estimation of the dollar value of the benefits. Assuming that each case avoided is a life saved and that it is possible to ascribe a value to human life, the annual benefits are merely the cases avoided times the value per life. However, these benefits vary depending on selection of risk estimates, reduction in exposure, and value of life.

Estimation of the risk posed by each microgram per liter of drinking water is a function of many variables. The Environmental Protection Agency's Office of Drinking Water reviewed the methodology used to develop two different risk estimates, one presented by the National Academy of Sciences and the other by the agency's Carcinogen Assessment Group.[19] The estimates are essentially the same, although arrived at using slightly different assumptions. A value of 2.08 times 10^{-6} cases per microgram per liter was used. The estimate reached by the Carcinogen Assessment Group was used in the analysis presented here to maintain consistency within the agency. The estimate is based on data from several animal studies and derived from a linear no-threshold risk model.

The consumption of drinking water per day varies according to climate and individual habits. Although recent data suggest that average daily consumption may be as low as 1.2 liters, the National Academy of Sciences' estimate of 1.95 liters per day was used in this analysis. Also taken from the academy, and generally accepted by analysts, is a life expectancy of seventy years.

The remaining independent component is the total reduction in exposure to trihalomethanes. The agency developed an estimate of this parameter. In a perfect world, one would first ascertain the exposure of the public to trihalomethanes and then assess how that exposure would change through use of various engineering alternatives. Unfortunately, it was not possible to define the exact preregulation exposure. The only data available

a. Includes only systems that chlorinate.

to assist in this estimate was the National Organic Monitoring Survey, which analyzed the water from 113 water supplies representing various types of sources and treatment processes.[20] About nineteen different contaminants were measured, including some of the trihalomethanes. These data were used to represent the preregulation distribution of trihalomethanes in water supplies. Although taken from a nonrandom sample, the data are the only basis upon which to estimate trihalomethane exposure. The number of people served by surface and ground water systems of various sizes was calculated from a statistical survey of the operating and financial characteristics of community water systems. Multiplying the percentages of the population affected by the population using drinking water, weighted by source of supply, leads to an estimate of the total preregulation national exposure. Figures 1 and 2 show the distribution of people exposed to trihalomethanes by concentration of the contaminant. Table 1 shows this exposure level for various population sizes.

Table 1. National Exposure to Trihalomethanes[a]

Level (micrograms per liter)	*Population*			
	Over 100,000	*Over 75,000*	*Over 50,000*	*Over 10,000*
Preregulation	6.1	7.1	8.6	11.4
150	4.1	4.7	5.7	7.4
100	3.1	3.6	4.3	5.8
50	2.0	2.4	2.7	4.0

Source: Calculated from U.S. Environmental Protection Agency, Office of Water Supply, Technical Support Division, "The National Organic Monitoring Survey," unpublished data.

a. The units of the table are in micrograms of trihalomethane levels multiplied by the number of people exposed, aggregated over the entire nation, or 10^6 gram persons.

To determine how the exposures presented in figures 1 and 2 would change after a regulation was implemented, a decision tree was constructed from information provided by water engineers asked to estimate the effectiveness of various water system treatments. The decision tree reflected assumptions about the combination of treatments that would be used, depending on the conditions within the different water supply plants. Further, the trihalomethane concentrations that will result from the treatments usually will be well below the maximum contaminant level standards. Only with the very expensive treatments (ozone and granular activated carbon) are final concentrations expected to be at the maximum contaminant level.

The national reduction in exposure to trihalomethanes is derived by subtracting the postregulation exposures from the preregulation exposures. These numbers, when combined with risk, consumption, and life expectancy, yield the number of cancer cases avoided each year by using various regulatory alternatives. To convert these cancer cases avoided to dollar benefits requires a simple multiplication with the value of life chosen by the analyst.

The national costs of the trihalomethane regulation are described in the economic impact analysis.[22] The particulars of the analysis are not unusual enough to warrant attention here. But it is important to recognize that even the cost analysis is subject to assumptions that can dramatically modify the national cost estimate. For example, the analysis included a contingency cost of up to 25 percent of capital to cover needs of the real world. If such contingencies are not really needed, as some environmental interest groups suggest, then costs would be significantly lower. On the other hand, certain water supply engineers, specifically

a. A value of $200,000 per life was used in each calculation.

those now suing the Environmental Protection Agency over this regulation, believe that most systems would use the more expensive treatments, causing national costs to increase significantly.

To emphasize this point, consider the effects of a change in assumptions on risk. Table 2 represents the range of net benefits when the risk assumption is varied. The risks associated with three different animal tests were used to develop the net benefits shown.[23] The only parameter varied in the risk estimates is the set of animal data used. Models of risk estimation remain the same, and the value of life used is $200,000. Yet this relatively minor adjustment in risk results in greatly different net benefits. The maximum net benefits vary sufficiently to allow for selection of several different trihalomethane standards. This phenomenon can be reemphasized by the interested analyst through selection of different extrapolation models, which can provide risk estimates two orders of magnitude apart.

Variation in cost assumptions produces a similar picture, as table 3 indicates. The relatively modest changes in engineering assumptions described above result in not so modest changes in maximum contaminant levels, which are economically different. The point is made again in table 4, where net benefit is described for various values of life. Again, only a small range of values of life is shown. Some estimates have gone as high as $158 million per life, which was the value of life imputed from coke oven emission standards.[24] Some are as low as ten thousand dollars per

a. A value of $200,000 per life was used in each calculation.

life, which is the amount society is willing to pay to preserve the life of an unknown individual through public nursing homes.[25] Within that range, nearly any national standard could be justified.

There is no obvious way to resolve these differences of opinion about technical assumptions, assumptions about risk, or, for that matter, the value of life. It is the tenuousness of these assumptions that reduces the utility of careful cost-benefit analysis, even for the relatively straightforward trihalomethane regulation.

Dear Drs. Hernandez and Anderson,

Enclosed are the responses from the outside reviewers who were asked to comment on the document "Additional USEPA Guidance for the Health Assessment of Suspect Carcinogens with Specific Reference to Water Quality Criteria".

Also enclosed is the list of reviewers I sent the document to and my letter of response to them. This response is compatable with the comments received in-house and from scientists who participated in Jerry Starra's workshops and with discussions held in the CAG.

You will note that the letter is, of course, non-committal about what the EPA is going to do. However, the reviewers gave a clear signal to go ahead with adopting the IARC criteria for stratifying the evidence for carcinogenicity. There should be no trouble getting SAB approval for such a move and it could have a major impact on the EPA's regulatory posture for a number of carcinogens.

The quantitative issue of treating mutagenic and non-mutagenic carcinogens differently could not be adopted in its present form without provoking a strong negative reaction from an important component of the scientific community. However, the revised approach suggested in the enclosed letter to the reviewers would stand a much better chance of achieving a consensus.

I hope you will approve the initiation of steps to seek Agency approval of the IARC criteria as well as efforts to revise the quantitative approach to make it more generally acceptable.

Sincerely yours,

Roy

REA/mff

[illegible] of that mechanism. Further, at this [illegible] may be enough dose- [illegible] with carcinogens to support the [illegible] extrapolation model [illegible] mutagenesis as the sole basis for the [illegible]hanism.

[illegible], as noted in this document, [illegible] mathematical models [illegible] the experimental dose range, they [illegible]sed for low dose [illegible] because of wide discrepancies that appear [illegible]t low doses. Point [illegible]tes can not be obta[illegible] without knowing t[illegible] exact dose response [illegible]e the true model can [illegible]ot be obtained from [illegible]ssay data, all that [illegible]plished is to consider the uncertainties [illegible]isk assessments. If [illegible] response is curving upward, linear extrapol[illegible] below the experimental [illegible]rovides an upper limit on risk. This shou[illegible] be able to be [illegible] with bioassay data alone and develops [illegible]ument independent of, [illegible] mutagenicity data.

[illegible] it appears reasonable to use th[illegible] limits from the [illegible] model as one means for arri[illegible] [illegible]e" exposure levels [illegible]opulation, it might also be reasonable [illegible] include some reference [illegible] sensitivities of humans and test animals as a final step. [illegible]tional toxicological approach discussed [illegible] page 9 should be [illegible]d, delineated or referenced, as should the mathematical procedures [illegible] extrapolation.

[illegible] it may well be the case that this so-call[illegible] conventional toxico- [illegible] gives essentially the same answer as [illegible]linear multistage model if it is also tied to the same level of risk, [illegible] should be. The [illegible] of the so-called conventional toxicolog[illegible]oach is that it is very [illegible] akin to conventional procedures. It should be cited that [illegible] dose response level, e.g. the 10% re[illegible]se level, and ex- [illegible] early below that point has [illegible] by Van Ryzin

J. Occup. Med. 22, 1980) and by Farmer, Kodell, and Gaylor (Risk Analysis 2, 1982) except that they suggested using the 1% response level.

Also, can one really call this approach a conventional toxicologic approach, which is based on the no-observed-effect-level (NOEL). Even if the NOEL exists, it has no precise meaning because it depends on the number of animals tested and hence provides a different level of risk in each case. Since the proposed technique selects a given response level (10%) and then applies an uncertainty (safety) factor, would it not be more proper to call this approach a "safety factor procedure" or "low dose linear extrapolation", since the two are almost identical.

3. The argument in paragraph 2 on page 10 is not logical. In the previous paragraph, a factor of 10 was imposed because of the uncertainty of sensitivity of humans. If then the data are available in humans (and presumedly their sensitivity is then known), one can not justify the use of the same uncertainty factor because you now have a greater certainty. If one is uncomfortable with only a factor of 100 when the data are presumedly more reliable, then the safety factor in less certain cases should be reevaluated. Therefore, the two paragraphs at the top of page 10 could, if you like, be replaced by the following paragraph:

> If the dose response curves upward, reducing the dose by an uncertainty factor of F will reduce the risk by at least a factor of F. Thus, starting at the dose that gives a 10% response, dividing by an uncertainty factor of 10,000 should reduce the risk to below one in 100,000. If the extrapolation is based on animal rather than human data, an additional factor may be employed depending upon the relative sensitivity of humans to animals.

3. Page 8, paragraph 2, line 2. Change "to use" to read "a modification of"; line 6, change "conventional toxicological" to read "modified".

4. Page 9, paragraph 2, line 1. Change "the conventional" to read "a modified"; line 2, delete "with an added refinement of making", replace with "which makes"; line 9, after "...tumorigenic responses." add the following sentence, "Also, NOEL has no definition and is a statistical result which depends on the number of animals tested." Line 14, after "....is recommended", insert "to estimate the 10% response level"; line 16 after "....upper confidence limit.", delete period, insert "on the response."

5. Page 10, delete paragraphs 1 and 2. Please see General Comments, above.

6. Page 12, sub-paragraph D, line 6, delete "In order to incorporate evidence for mutagenicity.", begin new sentence, "It is....."; line 7, change "both" to read "either", change "and" to read "or", change "conventional" to read "modified"; line 8, delete "a range of"; line 9, change "conventional" to read "modified". The two approaches are nearly the same when a risk level of 10^{-5} is specified for both.

7. The modified exposure limit needs to be tied to risk. It is difficult to provide an exposure limit without any notion of the degree of protection that it might provide.

8. Page 13, first paragraph. Delete last sentence: "It is proposed...... ....toxicological method."; second paragraph, delete all of the paragraph down to last sentence, "Such guidance, together....". As was stated above, one could divorce the process from mutagenicity and use other reasons for low dose linearity.

9. Page 12, sub-paragraph E, line 1. Change "could" to "should". Reference last sentence of paragraph No. 1 - Why shouldn't they be employed? Can we be so comfortable with best estimates that we don't need to allow for sampling errors and experimental variability?

Dear Roy:

Thank you for your letter of June 18 and the attached draft of a proposed addendum to the U.S. Environmental Protection Agency's Guidelines for the Health Assessment of Suspect Carcinogens.

In general, I believe the document represents real progress in attempting to relate evaluation further to the scientific and biological data. I enclose some comments which you may find of some value. Please excuse typographical and grammatical errors as I have not had as much time for polishing as I would like.

Sincerely yours,

Carcinogen Assessment Group
Office of Environmental Assessment
United States Environmental Protection Agency
Washington, DC 20460

Dear Roy:

I'm writing in reply to your June 21 letter to Vaun Newill. Vaun is out of the office, and in order to meet the rapid turnaround you requested, I have taken the liberty to respond in his absence.

Let me begin by saying that I am refreshed to see the Agency's interest in improving regulatory decision making procedures, particularly with respect to putative carcinogens. As your draft guidance document states, there is growing awareness of the need for flexibility in regulatory processes.

I note, however, a very one-sided view of the state of scientific knowledge of carcinogenicity. The EPA-modified IARC classification system considers only those data which support the conclusion that an agent under study is carcinogenic. This system of "stratification of evidence for carcinogenicity" is entirely blind to data from studies which show no carcinogenic effect, no matter how outstanding the effort or persuasive the results. "Adequate" evidence of non-carcinogenicity must be considered in a comprehensive and balanced assessment of cancer risk. The adequacy of negative findings from carcinogenicity studies can just as surely be judged as can the adequacy of negative findings from mutagenicity tests. Although I am prepared to accept that more rigorous criteria of adequacy will be required for negative findings than for positive findings, I feel that the acceptance of credible negative results (with some estimate of the "strength" of those results) is imperative. I suggest that the classification strata include a fourth set..."Adequate evidence against carcinogenicity".

3 of 7

The modification of the IARC classification system, as with the criteria for inclusion in Group 3, is particularly inappropriate. IARC recognized that some materials simply "cannot be classified" as to carcinogenicity. In the EPA draft document, this recognition has been restated as equivalent to "possibly carcinogenic". The terms "not classifiable" and "possibley carcinogenic" are simply not equivalent; whenever data are inadequate to support a conclusion, nothing more can be said. The inference the reader draws from EPA's modification of the IARC classification is that the Agency has presumed that all agents are suspect as carcinogens unless proven to be so...that is to say, all agents are classifiable as either possibly, probably or surely carcinogenic.

The notion that quantitative estimates of cancer risk may be legitimately made on the basis of mutagenic potency is neither theoretically nor empirically defensible. From the multi-stage model of the carcinogenic process, there is no reason to assume any direct relationship between the rate/frequency/incidence of the first stage event (mutation) and the rate/etc. of the ultimate event (clinical cancer). Even for those materials which have been shown to be both mutagenic and carcinogenic, very poor quantitative correlations between the two effects have been seen. To have assumed that the carcinogenic potencies of various agents were directly proportional to their mutagenic potencies would have required the following unsubstantiated and/or unjustified assumptions:

Don't understand

- That the mutation is the rate limiting step in the carcinogenic process.

- That the dose response functions for mutagenesis and carcinogenesis are parallel.

There are substantial empirical data to refute the assertion that carcinogenic potency (and associated risk) can be quantitatively estimated from the mutagenic potency of a particular material. In fact, work recently done by the American Petroleum Institute with highly-water-insoluble complex mixtures has failed to demonstrate even a qualitative relationship. This should not have been surprising; the results of mutagenicity bioassays (both bacterial and mammalian cell mutation tests) have proven to be highly method-sensitive and operator-sensitive. Results of carcinogenic bioassays are less method- and/or operator-sensitive but still vary sufficiently to support little hope for close correlation with the results of mutagenicity tests. For these reasons, the results of mutagenicity tests are totally useless for quantitative cancer risk assessment. At the very most, data from these studies may be used to qualitatively distinguish genotoxic from presumable non-genotoxic carcinogens. Even this application of the data must be done cautiously...with an eye to the method- and operator-sensitive nature of the results.

I take a rather simplistic view of the distinction between mutagenic (genotoxic) and non-mutagenic (non-genotoxic) carcinogens. A cancer is a cancer, by whatever mechanism may have lead to it. The only clinically important distinctions which have been revealed by animal experimentation are that non-genotoxic [illegible] tend (1) to be active only at higher doses (relative to genotoxic carcinogens) and (2) to display a "flatter" dose-response relationship. In either case (genotoxic or not), each increment of exposure is associated with some increment of risk, however small. All that separates the types of carcinogens, for practical purposes, are the vastly different rates at which the incremental risks accumulate...as functions of exposure.

The conventional toxicological approach has served the science and regulatory agencies well even when chronic, debilitating and irreversible health effects, such as chronic obstructive lung disease, were considered. My suggestion is that the "conventional toxicological approach", tempered by the judgment of trained, experienced and unbiased experts, be used in the standard setting process regardless of the health effect of concern. I feel a scientific policy decision will have to be made by our national policy makers as to what is a socially acceptable level of health risk. It then becomes the task of the toxicologist-oncologist-epidemiologist to estimate the relationship between exposure and risk, of the regulator to establish the target (or limit) for exposure, and of the environmental control technologist to devise the cost-effective means of achieving the target.

As for the passage entitled "Conventional Toxicological for Non-Mutagenic Carcinogens", I find it an odd mosaic of elements...ranging from relatively conservative to potentially quite lenient.. from practically reasonable to totally arbitrary. For instance, the use of the ED_{10} is attractive, and its use is well argued in the document. Its principal weakness, compared to the maximum NOEL, is that the ED_{10} can be (experimental circumstances determining) a much less conservative basis for extrapolation.

NOTE: As a parenthetical comment, I note an interesting conjunction in the document. This draft implies that the "NTP-type carcinogenesis bioassays" are "well conducted". In my opinion, they are certainly not well designed, at least, not for the generation of data suitable for use in extrapolative risk analyses. Their goal is to qualitatively segregate carcinogens from non-carcinogens...and the data are not suited to other ends.

The relative merits of dose determinations on the basis of maximum likelihood versus 95 percent upper confidence estimates are fairly and adequately covered. But the choice of the "uncertainty factor" is unnecessarily arbitrary. The ten-fold factors are apocryphal and enjoy no substantial basis. Recognizing the considerable heterogeneity within and among species, a ten-fold divisor for each is, in principle, not unreasonable. But, there is probably more variety both within and among species in their handling of non-mutagenic carcinogens than in their handling of mutagens, particulary if the mutagens are either direct-acting or require relatively little/non-specific metabolic activation. That is to say, the dose-response relationships for non-genotoxic carcinogens are "flatter" than those for genotox agents. In "conventional toxicologic" data analysis for standard setting, the principle is commonly applied that the flatter the dose-response relationship, the greater will be the required margin of safety over the NOEL.

The third factor of 10 is totally without scientific foundation and should not be mistaken for anything other than an arbitrary factor inserted for some non-scientific reason (humanistic sensitivity or political expedience).

The insistence that the first factor (to compensate for inter-species variation) is required, even when definitive data are available for man, seems illogical. If that ten-fold uncertainty factor is required for an adequate margin of safety, even when solid data are available, why wouldn't a larger uncertainty factor be in order when even less is known about the agent's effects in man?

The "criteria for evaluating...gene mutations" are reasonable.

I would like to have the "usual considerations that go into regulatory decision making" (see bottom page 13) listed and described in some detail.

Finally, I have no technical comments on the "options" as described in Section-E; however, a couple of philosophical observations are in order with respect to option 3. First, I feel have no objection to a

6 of 7

variety of standards (i.e., in different states) depending upon the environmental circumstances, the site, the water use, etc. Second, I feel that graded uncertainty factors are no more arbitrary than the safety factors suggested in the "conventional toxicological approach".

I hope these comments are helpful. I would be happy to answer any questions you might have. You may write me at the above address or call (201)273-6063.

Sincerely,

Steven C. Lewis, Ph.D.

Dear Roy:

Additional U.S. Environmental Protection Agency guidance for the health assessment of suspect carcinogens

Thank you for sending me the above document for review. I apologize for not responding more quickly. My comments will be confined to the first of the two issues addressed by the document, i.e., stratification of the weight-of-evidence for carcinogenicity. My experience in the utilization of mutagenicity data in the quantitative aspects of risk assessment is very limited as is my knowledge of the necessary mathematical manipulations.

I was very interested to find that EPA proposes to adopt the IARC methods for stratification of evidence for carcinogenicity. I have taken part in several meetings at IARC Lyon at which these methods were developed and used and I believe them to be the best that are currently available.

However, in reviewing Section B.1.3. of the EPA document I am not happy with the change from the IARC wording for Group 3 (Page 7, line 4). I prefer the original IARC version which clearly states that chemicals in this category cannot be classified as to their carcinogenicity in human beings. The EPA version seems to me to have a very different meaning by stating that these chemicals are "possibly carcinogenic for humans." In a sense the statement is a platitude because all chemicals for which the evidence is inadequate must be considered possibly carcinogenic but, in my opinion, to state it in this way could lead to misleading interpretation particularly in the law courts. I would recommend the retention of the original IARC wording.

I believe that the increasing evidence in support of the existence of genotoxic and non-genotoxic (or epigenetic) carcinogens warrants the introduction of this concept into approaches to the definition of exposure limits to certain carcinogens. This, of course, implies support for the "conventional toxicologic approach to defining exposure limits in terms of the no-observed-effect-level of response together with an uncertainty factor."

1of7

I am less happy with the selection of 1,000 for this factor. I suppose that one must recognize the arbitrary nature of the factor and I cannot make a very convincing case for an alternative. However, a factor of 1,000 does seem rather high to me if we really accept that some carcinogens do not act by the genotoxic mechanism and should not therefore be subjected to quantitative risk evaluations that are based on the assumed irreversibility of genotoxic (mutagenic) injury.

If I can be of any further assistance please let me know.

With best wishes.

Sincerely yours,

Peter

Dr. Roy E. Albert
Chairman
Carcinogen Assessment Group
Office of [illegible] Environmental Assessment
U.S. Environmental Protection Agency
Washington, D.C. 20460

Dear Roy:

I and several members of our staff have reviewed the proposed addendum to the U.S. Environmental Protection Agency's guidelines for the assessment of suspect carcinogens entitled:

> "Additional U.S. Environmental Protection Agency Guidance for the Health Assessment of Suspect Carcinogens with Specific Reference to Water Quality Criteria"

The following are our general concerns about the document.

A. Even well informed readers, including many toxicologists, are not likely to know what the multistage extrapolation model used to calculate the 10% response is. They will also not know how in vitro mutagenesis assay measurements can be used to calculate a cancer risk probability of 10^{-5} for people. These are two crucial pieces of information that are necessary for reviewing the appropriateness of this addendum. Clear explanations of these procedures should be included in the addendum or references should be made to other reports that can be easily obtained. As it now stands, it would be extremely difficult for anyone to independently calculate the risk factors given in Table 2 of the document.

B. Although one clearly stated purpose of this addendum is to stratify weight-of-evidence judgements about cancer causing agents, too many adjectives are used. The words, sufficient, limited, inadequate, strong, confounding, suggestive, almost sufficient, possibly, adequate, inconclusive, negative, are used to describe evidence of chemical carcinogenicity. None of these are defined very clearly. The number of these terms used should be limited and those used need clear definition.

C. Two concerns are likely to occur to readers of this addendum that should be discussed, even if they cannot be treated in a satisfactory way. These include exposures to mixtures of chemical carcinogens and to potential carcinogens for which no toxicological information is available. Exposures to mixtures of carcinogens and new chemicals is likely to occur for most people.

Operated for the U.S. Department of Energy under Contract DE-AC04-76EV[illegible]013
An Equal Opportunity / Affirmative Action Employer

D. Using a 10 cancer response level developed from studies in laboratory animals or people to estimate numerical exposure guidelines needs further definition. Does this criteria apply only to single types of tumors? Are these for life span studies only or for studies of shorter duration?

E At least two parts of this addendum attempt to provide detailed discussions of factors that remain very arbitrary. These should be simplified. [illegible] use of the safety factor of 1000 described on page 10 and use of aritnematic or geometric means of the calculated acceptable levels of exposure to carcinogens after page 12. These are arbitrary judgements and should be stated as such.

Overall, we feel that giving more attention to the above factors would improve the quality and usefulness of the addendum. If any of these concerns are not stated clearly in the above discussion, please feel free to contact me (FTS – 844-6835), Dr. Charles Hobbs (FTS – 844-2435) or Dr. Richard G. Cuddihy (FTS – 844-7544) for a further explanation.

Sincerely,

Dr. Roy E. Albert
Chairman, Carcinogen Assessment Group
Office of Research and Development
United States Environmental Protection Agency
Washington, D.C. 20460

Dear Roy:

We have studied your draft of the proposed addendum to the U. S. EPA guidelines for the health assessment of suspect carcinogens with reference to water quality criteria.

We are pleased to see that the EPA is reconsidering its guidelines with a view to consideration of both the quality of the data and the biological properties (e.g., whether or not mutagenic) of the chemicals under consideration. We do not have sufficient time at present to study the draft intensively; thus we are not ready to approve or disapprove it. However, we do have the following comments for your consideration:

1. We do not find the classification of chemicals with regard to their carcinogenic risks to be adequate.

    a. Groups 1, 2A, and 2B are acceptable classifications as described on p. 6.

    b. Your definition for chemicals in Group 3 is inadequate and misleading. Especially among lay persons, but also among some scientists, the statement that a "group of chemicals is possibly carcinogenic for humans" infers that this is a fairly likely situation. This statement is quite different from the IARC statement that a "group of chemicals cannot be classified as to its carcinogenicity for humans." We strongly feel that the IARC statement should be used.

    c. Omission of groups 4 and 5 of the IARC from your classification (i.e. having no categories for chemicals for which the data are clearly negative and those for which there are no data) is very unfortunate. These categories should be included so that any chemical can be put in an appropriate class. In these cases, we assume that no permitted levels would be established.

[illegible]. The introduction of two methods of calculation of acceptable levels and presentation of some guidelines for the use of values obtained by both procedures in setting standards is a useful move toward individualizing decisions on chemicals with regard to their biological activities. Further modification of the procedure will doubtless be needed as further data become available.

Dr. Roy E. Albert, Chairman
Carcinogen Assessment Group
Office of Environmental Assessment
Environmental Protection Agency
Washington D.C. 20460

Dear Roy:

Thank you for this opportunity to comment on the draft of a proposed addendum to the EPA guidelines for the health assessment of suspect carcinogens with specific reference to water quality criteria. Our concerns with the draft center on three points.

First, although the IARC criteria for assessing the quality of evidence for carcinogenicity in experimental animals are to be used, the caveats attached by the IARC Working Group to the use of such data in quantitative assessments of human risk have not been included. Specifically, the IARC Monographs Preamble states, "Data that provide sufficient evidence of carcinogenicity in test animals may therefore be used in an approximate quantitative evaluation of the human risk at some given exposure level, provided that the nature of the chemical concerned and the physiological, pharmacological and toxicological differences between the test animals and humans are taken into account." We share the Working Group's concern that tumor incidence in a bioassay alone is an insufficient basis for quantitative assessment of human risk.

Second, in cases where the compound is mutagenic, we are concerned that the theoretical arguments which support the multi-stage model of carcinogenesis are being misinterpreted to support use of this model with administered dose as the independent variable. It is crucial to understand that all theories of carcinogenesis are framed in terms of the amount of active agent present in specific target tissue, i.e., delivered dose, rather than administered dose. The biologic plausibility of the linearized multi-stage model, or, indeed, any model of carcinogenesis, rests fundamentally on this delivered dose concept. Put simply, only what is present at a site can cause cancer there. Therefore, the mutagenicity of a chemical compound, by itself, is not sufficient to justify use of the linearized multi-stage model with administered dose as its independent variable. Indeed, it may be that in no case is it appropriate to use administered dose as the independent variable, since this would require strict linear proportionality between delivered and administered doses over the entire dose spectrum.

Careful consideration must be given to the structure and function of the whole animal systems which regulate how much of the administered dose actually reaches a specific target site. The quantitative relationship between delivered and administered dose is likely to be highly specific to the compound under investigation, its route of administration, and to the exposed species as well. Consequently, it seems unlikely that any single "formula" approach to quantitative risk assessment, even for mutagenic agents, will be universally applicable.

Third, we have a related concern with the proposal for a conventional toxicological approach for "non-mutagenic carcinogens". Although conventional practice is to convert doses across species on a body weight basis, there is no scientific basis for assuming this scaling rule to be universally applicable. Rather, professional scientific judgment on a case by case basis is required, and uncertainty regarding the conversion should somehow be incorporated into the assessment.

We appreciate the opportunity to provide these comments for your consideration. If you foresee a need for elaboration on any of these points, please feel free to contact us by letter or telephone.

Sincerely,

Bob

Dear Roy:

As you know, your proposals on risk assessment came to me while I was away from my office. I have been over them now and will respond.

The use of the IARC formula for stratifying the evidence is excellent. It has pretty well stood the test of repeated application and has the additional advantage of being reasonably familiar to most of the users of IARC documents.

I am not at all happy about the two-fold classification of genotoxic agents and non-genotoxic agents. Although we have come a long way in the last few years in understanding some of the details relating mutagenicity to carcinogenicity, I don't think we have the sharpness of methods required that all of these agents now deemed "negative" for genotoxicity will in the long run turn out to be negative; moreover, a grouping under the label of non-genotoxic is by its very nature a motley group of diversely acting agents; I see little advantage and some disadvantage in lumping all of these together in this way.

As you know, I have strongly supported the use of quantitative risk assessment as an important input into the evaluation and eventually the regulation of carcinogenic chemicals. I doubt that it can ever become the sole basis for our regulatory decisions considering all of the technical uncertainties in current procedures for quantitative risk assessment. (I refer here primarily to laboratory data rather than epidemiological data.)

I think that one should continue to use quantitative risk assessment along the lines that CAG has in the past. Obviously, where one has special information on any agent, genotoxic or "non-genotoxic," one

SESQUI
CENTEN
NIAL 1831
CELE 1981
BRATION

should use such knowledge in estimating risk. With that provise, I am not at all troubled by using current mathematical procedures for the "non-genotoxic" chemicals. Always with the usual caveats plus the additional qualifications that may need to be added when applied to compounds negative for genotoxicity. I believe that such procedures are justified as a crude basis for estimating a probable outer limit of risk. Such estimates would, in any event, be used as only one input along with other information in estimating risk and reaching regulatory judgments.

This leads me to another reservation in the use of the safety factor approach which your document proposes. The use of the safety factor as proposed undertakes to establish an acceptable level of exposure. That is equivalent to overtly setting a number which could become a control or a regulatory statement. As you know, I have always felt that there should be two stages in regulation: the first is the technical assessment of risk, preferably as something equivalent to a crude dose response curve, and the second would be for the regulatory agency to take this information and make a regulatory decision in the light of socio-political and economic considerations. As you describe it, the safety factor approach jumps immediately from the first to second step and fails to take into account those balancing circumstances that in most cases are required.

If you were to use a straight line from the 10% incidence estimate down to zero and use that line as the dose response curve, that would overcome my objection of jumping from the first step to the second.

Finally, it may be desirable to consider a major review of quantitative risk assessment at the national level, perhaps through the National Academy of Sciences/National Research Council. I am sure that there will be differences of opinion scientifically and philosophically, but a responsible group faced with the recognition that some degree of quantification with appropriate estimates of uncertainty will be a useful ingredient in the standard setting process (wherever the data permits) will come out with constructive proposals.

Sincerely,

Norton

(RD 689)
Washington, D.C. 20460

Dear Dr. Albert:

Thank you for sending me a copy of the "Additional U.S. Environmental Protection Agency Guidance for the Health Assessment of Suspect Carcinogens with Specific Reference to Water Quality Criteria." To get straight to the point, I do not agree with the fundamental premise of this paper -- that non-mutagenic carcinogens are of less concern than those that are mutagenic. I believe that the distinction is not based on sound scientific data and relies on certain questionable assumptions.

The draft states that for carcinogens that do not give evidence of the ability to induce gene mutations, the use of the linear non-threshold dose-response model is not plausible. It therefore proposes that for non-mutagenic carcinogens, the less conservative (NOEL) approach be used as a basis for setting standards.

My major concerns are as follows:

(1) There are inadequate scientific data to support this distinction between mechanisms. Somatic mutation is only one of the ways in which a chemical substance may cause cancer. Gene and chromosomal rearrangements, changes in chromosomal number or structure, disruption of cellular differentiation, activation of proto-oncogenes, DNA damage, and disruption of DNA repair systems are some of the other possibilities. Thus, both genotoxic (broadly defined as disturbance at the level of the DNA, the gene, or the chromosome) and/or non-genotoxic mechanisms may be involved. All must be considered of equal importance. Thus, to equate "mutagenicity" with "genotoxicity" with "the most serious carcinogenic mechanism" does not appear to be sound.

Public Lands Institute: 1720 RACE STREET • DENVER, CO. 80206 • 303 377-9740

100% Recycled Paper

(2) There is a lack of data establishing a threshold for non-mutagenic carcinogens or that the dose-response curve is different in the lower range from that for substances that cause gene mutations. On the contrary, the literature on ionizing radiation shows a linear/quadratic dose-response curve for chromosomal aberrations in which the curve intercepts the point of origin.[1]

In most cases, however, we do not know enough about the dose-response curve of non-mutagenic or even non-genotoxic carcinogens (as broadly defined above) to draw conclusions about its shape at low dose levels or about the existence of thresholds. With tumor promotors in general, the studies needed to understand the dose-response curve -- studies administering the test substance over a wide range of dose levels -- have not been carried out. Thus, as the draft acknowledges, "[w]e currently do not know enough about the mechanism of action of non-mutagenic carcinogens to plausibly extrapolate dose-response relationships for such agents to low levels of exposure." (p.8). To give an example, DES is probably one of the most studied of the hormones; yet the animal and human data do not provide a distinct dose-response curve.[2] Even a recent large-scale bioassay of DES[3] leaves questions about details of the lower range of the dose-response curve. Thus, I would agree that:

> [i]n general, it would seem that a chronic elevation above the level of endogenous estrogen production would qualify as a potential carcinogenic dose.[2]

At a recent workshop on EPA's ANPR on Volatile Organics in Philadelphia on July 21-22, Dr. William Lijinsky pointed out that we cannot yet design the experiments to determine whether there are thresholds at low doses (and thus cannot begin to set a threshold for carcinogenicity in humans). In particular, he emphasized that it is not now possible to establish a threshold for humans that takes into account differing organ sensitivities as well as other relevant factors. For example, in bioassays with diethylnitrosamine (DEN), Dr. Lijinsky has observed liver tumors at high doses while esophageal -- and not liver -- tumors appear at low doses. Had the experiments at lower doses not been carried out, one might have concluded the existence of a threshold for DEN based upon the induction of hyperplasia at high doses. Therefore, as IARC states:

> [T]he limited knowledge about the mechanisms of action of chemical carcinogens and about the multistep carcinogenic process preclude any rigid categorization of carcinogenic agents.[4]

(3) Beyond these uncertainties at the experimental level, the distinction between carcinogens on the basis of mechanism of action (where it were possible) appears to be of questionable practical value. This is because of the practical impossibility of identifying population thresholds given the lack of data at low dose levels, variations in individual human responses[5] (due to genetic factors, health status, and life history), and possible additive or synergistic effects of other agents to which individuals are exposed.

This is particularly true for halogenated organic water pollutants which show synergism with other environmental chemicals (e.g., MFO inducers) and which may themselves enhance the effect of other halogenated organics. Further, many of them act on the same organ, the liver, and are known to bioaccumulate. The fact that individuals have continuous lifetime exposure to the combination of organic contaminants in drinking water (some of which may be inhibitors, some promotors, some complete carcinogens) -- albeit generally at low doses -- argues against assumption of a safe level or threshold effect in the human population.

Additional complicating factors in carcinogenesis are time and duration of exposure. These factors may be as significant as dose itself; yet my impression is that we generally know as little about their specific role as about the lower range of the dose-response curve. Exceptions are DES and estrogen. The stage in embryonic development at which DES exposure occurs is established as a critical factor in vaginal cancer, as is duration of exposure to estrogen in the production of endometrial cancer.[6] It appears that with tumor promotors in general, frequency and duration of exposure -- as well as dose level -- are critical factors in the production of tumors.

(4) The policy resulting from the "double standard" approach in the draft will be considerably less protective than the present policy. Furthermore, according to Table 1 of the draft, absence of data or inconclusive data would cause EPA to use the less conservative NOEL approach or a midrange value rather than the linear extrapolation method. In Table 2, 10 of 14 compounds are characterized as having inconclusive or inadequate data on mutagenicity. As the table shows, the NOEL approach yields estimated standards that exceed those based on the CAG model by a factor of 10-369. Given the real problem of "false negatives" in mutagenicity assays arising from inappropriate metabolic activation systems etc., it seems unwise to use inconclusive or inadequate data for mutagenicity as a basis for a less protective standard.

(5) Somewhat hidden in the document is a change from the generally accepted procedure of giving guidance based on the range of risk values 10^{-5} - 10^{-7}. This is a significant policy change that must be extremely well documented before adoption; yet it is not supported by any discussion in the text.

* * *

In light of all of the above, I believe that EPA should solely use the conventional CAG model rather than alternate with the old-fashioned NOEL approach that has been modified to use MLE and body weight rather than surface area conversation. As you know, the conventional linear multi-stage model is by no means the most conservative model that could be used to extrapolate human risk.[7] At the Philadelphia conference mentioned earlier attended by Dr. Marvin Schneiderman, Dr. Robert Neal, Dr. William Lijinsky and others, the health effects working group concluded: "The multi-stage model is appropriate for both genotoxic and non-genotoxic compounds, thus distinctions between genotoxicity and non-genotoxicity are not relevant." Furthermore, in using the linear model, I believe that EPA should continue to give guidance based on the range of risk values 10^{-5} - 10^{-7}, rather than only 10^{-5}.

I hope these comments have been helpful and I would be happy to discuss these questions further. I hope your European trip was enjoyable. How are the crowds in Italy?

Sincerely,

Frederica P. Perera

MEDICAL SCHOOL, UNIVERSITY OF WISCONSIN

June 24, 1982

Dr. Roy E. Albert
Chairman, Carcinogen Assessment Group
Office of and Environmental Assessment
U. S. Protection Agency
Washington, 20460

Dear Roy,

With reference to your letter of June 18, I have had an opportunity to look over the proposed addendum to the EPA guidelines that you sent and would offer the following suggestions.

In general I am very happy to see that a federal regulatory agency such as the EPA is beginning to consider in a serious manner more of the available facts regarding the process of carcinogenesis and their relationship to possible human risk. As our knowledge of the natural history of neoplastic development increases I would hope that the Agency would continue to look at all the facts in relation to cancer risk assessments. Further I would hope that this approach to guidelines in this area would be extended to other environmental areas as well.

More specifically there are several points in the document for which I would suggest the following alternatives:

1. In the consideration of the stratification of the weight-of-evidence judgements, it would seem scientifically proper to consider the efficiency of repair of DNA damage caused by a specific agent as well as its pharmacokinetics. While I realize that these two variables take considerably more effort to determine, where such data is available I would feel that it would be important to include it in the weight-of-evidence judgments.

2. The term "tumour" which is used on the top of page 4 is taken directly from the IARC assessments. This term is not commonly used in the United States when speaking of neoplasms and it can be confusing since a tumor is not necessarily a neoplasm. In the final document I would hope that the term, neoplasm, is used throughout rather than a combined set of terms which can be confusing.

3. I do not understand the footnote at the bottom of page 3 which indicates that two IARC categories, negative and no data, were deleted. There certainly are instances where no data is available and this would be important to risk assessment. Negative studies are becoming more obvious with more and more compounds being investigated. I do not feel that the regulatory agencies should be afraid to call something negative if that's

450 North Randall Avenue Madison Wisconsin 53706 608-262-2177

what all the available data shows. I am not one to argue that no matter how much negative data is available, one can never by absolutely certain that under some esoteric condition a material may be found to be positive in a specific test. If such a philosophy were to be accepted then in fact all materials in our environment are suspect carcinogens simply because we can never complete all possible tests on any single agent.

4. I do not think that the original IARC wording for group 3 (page [illegible]) should be changed as you have it. The term "possibly carcinogenic . . . humans" signifies to many if not the majority of lay individuals that such chemicals are likely to be carcinogenic. The IARC designation clarifies this point and is to be preferred.

5. Rather than arbitrarily taking an uncertainty factor of 1000 wouldn't it be reasonable to estimate such factors where some of the data is known such as with aflatoxin, DES, chlornaphazine and determine what the order of uncertainty would have been with these compounds. Furthermore one could guess at some of these factors with a number of other known human carcinogens based on more recent animal data, e.g. vinyl chloride, antineoplastic agents, etc. In doing this such estimations would have more basis than simple guesses.

6. The use of the term "chromosome mutations" is not clear to me. If translocations, transpositions, chromosomal deletions and polysomies are meant by this term than I feel that this should be indicared somewhere in the text. The sentence on page 11 (ll 17-22) is even more confusing when related to "primary DNA damage". Furthermore as you know there is more and more evidence accruing that chromosomal abnormalities may be the most critical factor involving the genome in relation to the initiation of neoplasia.

I hope that my questions and suggestions don't sound too naive. Obviously you look at such guidelines in a different light than I. However I hope these thoughts may be of help to you in your deliberations. If I can be of any other assistance, please don't hesitate to let me know.

With kindest regards,

Henry

U. S. Environmental Protection Agency
Washington, D.C. 20460

Dear Roy,

I received your letter of June 21 requesting my comment on the draft EPA proposal on "Guidance for the health assessment of suspect carcinogens with specific reference to water quality criteria." I am leaving today (6/26/82) for Europe and in the last few days I had to finish our Annual Report and other pending documents. Therefore I have had no time to prepare a more detailed, annotated review of this proposal. The present comments strictly express my personal scientific views and are clearly not intended to represent any official position of the National Cancer Institute. I am only addressing the science aspects, and not the policy aspects which are outside my present scope.

The draft contains many assumptions and deductions that are, in my view, lacking scientific justification.

The cornerstone of the draft is the distinction of carcinogenic substances in the two categories of genotoxic and non-genotoxic. This distinction has been recently proposed in the scientific literature, e.g. by John Weisburger and Gary Williams, but the evidence for such a diverse pathway in the mechanism of action of carcinogens is far from clear. While we do know of many carcinogens as being genotoxic as shown by their mutagenic activity, the quantitative correlation of mutagenicity with carcinogenicity is poor, as is documented in the working paper by Ian Purchase of I.C.I. for the forthcoming SGOMSEC meeting on risk assessment to be held in Rome on July 12-16, 1982. The neoplastic transformation of cells in culture can be a much more frequent event than the induction of a gene mutation in the same cells. Carcinogenic, co-carcinogenic, promoting and cell growth-regulatory factors may concur in the induction of neoplastic expression. At the molecular level, the sequence of biological changes required to start a neoplastic process is not yet elucidated, although the rapid progress of molecular biology methods is now allowing us to probe it more closely. There are indeed some carcinogens for which no evidence so far has been gathered of a direct mutational mechanism.

Considerable interest has been generated by the possibility that a major mechanism of carcinogenesis may consist of a derepression of certain genes that function as suppressors of oncogenic information already present in the cell. Such functional gene regulation may not require a mutational event in order to be started, but the kinetics of such "toxic" mechanisms are still unknown. Many different concurrent factors may take part in the process of carcinogenesis and I know of no evidence that would exclude a linear type of dose-response relationship. The draft proposal embarks on such a hypothetical distinction as "genotoxic versus non-genotoxic" but rapidly runs out of steam when it has to come up with the criteria for such a classification (section c.2) and concludes with a nondefinition for non-genotoxicity (p.12), stating that the criteria may vary from chemical to chemical and will be left to professional judgment (not otherwise defined). Lack of detection of mutations in a few test systems is not sufficient to exclude a mechanism that may damage the genetic control of neoplastic expression in the human organism.

For practical purposes, nationally and internationally accepted scientific criteria for carcinogen identification have required precise definition of bioassay methods, and tests of their reproducibility and predictiveness. These are completely lacking in the proposed draft, and yet this determination represents its pivotal point.

On the point of "stratification of the weight of evidence", the adoption of a classification comparable to that used by the IARC monographs is intended here for a differential regulatory use, while the IARC classification is addressed mainly to distinguishing the amount of information available for a substance. A substance may be a highly effective carcinogen for humans in certain conditions but bioassay evidence may appear "limited" or "inadequate" if the bioassay system is biologically inappropriate or the test design inadequate. We know of several examples of substances that were known to be carcinogenic in humans and for which it took considerable time to find the adequate test conditions to reveal the effect in animals: examples include several aromatic amines, inhalation of polycyclic aromatic hydrocarbons, benzene, and the still pending example of arsenic.

If the IARC classification is considered, my major concern is to improve on the definition of "sufficient" and "limited" evidence: I have found that the current IARC definitions are not mutually separated by clear criteria, are confusing in their use of malignancy criteria, and inaccurate in the inclusion of "lung and liver tumors in mice" as examples of "neoplasms....that often occur spontaneously or are difficult to classify as malignant by histological criteria alone". There are strains of mice in which lung and liver tumors do not seem to occur often spontaneously and there are lung and liver tumors that are easily classified as malignant, even by histological criteria alone. If the IARC reference is used, one could at least specify: "lung adenomas and liver cell adenomas (hepatomas) in certain strains of mice". I have published some comments on this issue a couple of years ago and I refer you to those comments in the enclosed reprint (Saffiotti, U., J. Toxicol. Environ. Health, 6: 1029-1057, 1980, page 1035, footnote 1).

On p. 7, line 4, of the draft proposal, the definition of group 3 chemicals as "possibly carcinogenic for humans" is confusing; it is adequate if it refers to compounds for which there is limited evidence of carcinogenicity, but for compounds with inconclusive evidence only, the IARC wording is more accurate and these could constitute a separate group.

On page 7, the draft begins discussing the use of mutagenicity criteria. I have given you my general comments above. Here are some more specific comments.

- p. 7, line 9, etc.: the rationale for use of the linear non-threshold model is not heavily dependent on the mutagenicity of carcinogens, and the biological justification for its use does not lie in the correlation between carcinogenesis and mutagenesis. This is one of the most distorted arguments in the draft.

- p. 8, lines [illegible] ar model is just as "plausible" in the absence of demonstrated gene mutations by a given agent, unless there is very heavy direct evidence of another dose-response pattern at appropriately low doses. The selection of a particular model cannot now be based on the "required" acceptance of a mechanism of action, since the intimate molecular control mechanisms in carcinogenesis are still unknown. We know so little about the hypothetical non-genotoxic mechanisms for cancer causation that it seems highly premature to presume to treat them differently from those of other better known carcinogens, when the overall biology of the induced cancers is quite comparable.

- p. 8, line 14 etc, and p. 9, c.1: the draft proposes the use of a "conventional toxicologic approach for non-mutagenic carcinogens". What is "conventional" about an approach that does not fit the evidence? There is no such thing as "conventional" toxicology, if toxicology is to reflect the variety of chemical-biological interactions. The approach described as "conventional" was the approach developed during the Stone Age of toxicology, which I find best described by this statement I once heard: "Find a no-effect level in animals, divide by 100, and pray". This type of "conventional" toxicology has been rejected a long time ago as irrelevant to the evaluation of self-replicating toxic effects, no matter how induced. In cancer induction what is fundamentally different from toxic degenerative pathology is that the induced neoplastic state makes the target cell proliferate rather than die off; and therefore, the health effect keeps progressing when the toxic agent is no longer there. It is the neoplastic condition that is progressive, not the existence of a mutagenic mechanism; on the specific role of induced mutations in carcinogenesis, even for mutagenic carcinogens, there is still ample speculation.

I do not have time to comment on the tables and applied examples given in the draft, except for confirming my personal feeling that they are based on inappropriate premises, as discussed above. I believe that an excellent criticism of the attempt to regulate carcinogens on the basis of numerical and arbitrary risk estimates was given in the 1980 Report of the National Research Council's Committee on Prototype Explicit Analyses for Pesticides, entitled "Regulating Pesticides." As you know I am extremely skeptical of our present ability to arrive at any reliable numerical risk estimate of carcinogenic risk in the human population on the basis of bioassay data, while I think that well conducted bioassay results, critically analyzed and integrated with relevant research results, can give meaningful qualitative risk evaluations for use in public health.

These are my personal reactions to the draft you sent me. I will be glad to discuss them further when we meet in Rome.

Looking forward to seeing you soon, I remain.

Very cordially yours,

Umberto Saffiotti, M.D., Chief

Enclosure

TELEX FROM LORENZO TOMATIS, IARC, Lyon, France, July 6, 1982

TO: Roy E. Albert, M.D.
Chairman
Carcinogen Assessment Group Office of Environmental Assessment
U.S. Environmental Protection Agency
Washington, DC 20460

Having seen your letter 22 June, 1982 only today, and given the urgency you mention, I list below a few immediate comments:

Alt[illegible] chemicals may eventually receive different treatment according [illegible] mechanism by which they exert their carcinogenicity, there is at present considerable uncertainty on how categorization of chemicals could be established. At present, it appears that the basis for justifying any form of extrapolation down to levels of risk in the order of 10^{-5} is very weak.

Page 4: The definition of limited evidence has been slightly changed as point c) in this paragraph now reads: "The neoplasms produced often occur spontaneously and have in the past been difficult to classify", etc.

Page 5: The definition of limited evidence drafted by IARC says limited evidence of carcinogenicity which indicates that a causal interpretation is credible, but that alternative explanations, such as chance, bias or confounding, could not be adequately excluded. Inadequate evidence which indicates that one of three conditions prevailed:

(A) There were few pertinent data;

(B) The available studies, while showing evidence of an association, did not exclude chance, bias or confounding;

(C) Studies were available which do not show evidence of carcinogenicity.

Page 7: The definition of group 3 given by IARC seems much more appropriate. The new version would seem rather loose. It is important to keep in mind that for the chemicals in group 1, the categorization is final, but for chemicals in groups 2 and 3, the categorization may change when, and if, new data become available. To classify all group 3 chemicals as limited forcibly excludes the category inadequate.

Page 14: The grouping in Table 1 of the IARC groups 1, 2A and 2B under sufficient, and IARC group 3 as limited does not appear correct.

A copy of the introduction methods and results section of the new IARC supplement 4 updating IARC supplement 1 have been sent by airmail.

TO: Dr. Roy E. Albert

FROM: Dr. Arthur C. Upton

SUBJECT: Proposal addendum to EPA Guidance for the Health Assessment of Suspect Carcinogens

In response to your letter of June 18, I have reviewed the proposed addendum to the EPA Guidance for the Health Assessment of Suspect Carcinogens, with Specific Reference to Water Quality Criteria. In general, I find the proposed approach to be well conceived and appealing. I would suggest, however, that it be referred for comment to others who are more expert than I in assessing the risks of chemical carcinogens; eg, I. B. Weinstein, S. Weinhouse, U. Saffiotti, D. G. Hoel, H. Pitot, A. Whittemore.

A few minor editorial comments and corrections include the following:

page 5, line 15: "is" should replace "are";
page 7, line 4 et seq: how to deal with chemicals for which there is strong evidence that they are not carcinogenic?
page 8, line 10: the plausibility of the linear, non-threshold model is buttressed by data on *in vitro* cell transformation and by data on the carcinogenic effects of high-LET radiation in humans and laboratory animals;
page 10, line 7: "are" should replace "is";
page 10, line [illegible]: "uncertainty" is misspelled
page 12, lines 1-2: this statement seems redundant with the preceding
page 13, line 18: "criteria" is plural;
page 19, line 2: replace "criteria" with "criterion"

Many thanks for the privelege of reviewing the draft proposal. If there is anything further I can do to help you, please don't hesitate to let me know.

Office of Environmental Assessment
U.S. Environmental Protection Agency
Washington, D.C. 20460

Dear Roy:

I read your Guidelines for Health Assessment of Suspect Carcinogens with considerable interest and I am outlining my comments as follows.

Stratification is OK, but has to be done with great caution and with every effort to avoid undue substratification. I would go along with the IARC categorization and would suggest these to be as follows:

1. Sufficient evidence;
2. Limited evidence;
3. Inadequate evidence;

and possibly a fourth, negative evidence.

I would use exactly the same categories for human studies and for mutagenicity, thereby stratifying in the same manner each method of assessing carcinogenic activity. I don't think that other categories or substratification is warranted. One gets down to hair splitting, subjective judgments, and all of the personal viewpoints that lead to disputes and disagreements. I believe that regulatory agencies can feel comfortable with these four categories but they should be accompanied with proper textual elaboration, since each putative carcinogen has its own peculiar qualities and characteristics, and risks to specific populations.

As you know, I have decided views against mathematical quantitation of risk. At one time I favored such quantitation, but as I learned more about the pitfalls of interpretation and extrapolation from high doses to low doses and from animals to man I realized there is a limit to what can be done with data particularly when they are often fragmentary or contradictory or incomplete.

No matter how sophisticated the mathematical model, the results can have no greater significance than the original data from which they are derived.

This situation may not apply to ionizing radiation where there is a massive body of human as well as experimental data, much of which covers responses to graded doses even down to low levels. Still, the sharp and shrill disagreements that plague radiation carcinogenesis assessments should caution us to beware of quantitation in the field of less defined chemical carcinogenesis. Where there is so much room for individual judgment it is difficult or impossible to have experts agree on the significance or statistical errors of mathematical modeling, and in my judgment (which I realize may be somewhat biased), I believe that with all these defects of interpretation and the uncertainties of model building, the estimations of risks in quantitative terms are sterile academic exercises.

As I read your report, I think you give too much significance to mutagenicity data. It is true that there are some parallelisms. On the other hand there is a large body of evidence against mutation as the only mechanism of carcinogenesis and in fact there is a good deal of evidence against mutation. I am enclosing a recent article of my own which appeared in the JNCI in which I briefly discuss epigenetic versus genetic mechanisms and give a few references to thinking on this subject by other investigators. Another paper in this category is by Straus, JNCI 67, 233, 1981. Unless we know more about the mechanisms of cancer induction, I do not think that we can implicate theoretical conceptions such as mutation, initiation, promotion, etc. as bases for regulatory decisions affecting large populations. Too much is being made of mechanism, about which we still know little.

I will close by saying that I am strongly against the use of conventional toxicological approaches to estimate risks of chronic toxicants such as carcinogens. You use a factor of 1000 to assess carcinogenic risk. Your data of Table 2 indicate however, that there is an uncertainty factor in comparison with your linear extrapolation model of at least 100 or more. The conventional toxicologic approach is OK for acute, reversible toxicity but is a mockery for chronic, irreversible toxicity.

In summary, my own philosophical outlook turns me away from putting numbers on risk assessments. No matter how many caveats you place on your data, you may be sure that they will be used by regulatory agencies and their attorneys as graven in stone. I feel they are not only misleading but are subject to such a battery of objections and misinterpretations as to make them virtually useless for defensible regulations. It is far better I believe to say that the data are not of such nature to be subject to quantitation. In my judgment, I believe you are trying too hard to obtain figures which by their very nature are going to be provocative and extremely difficult to defend.

I hope you find these comments constructive and I hope that I have not been too critical. Believe me, I do commend your tireless efforts toward risk quantitation, even if I have to disagree with their value in establishing regulatory guidelines. I hope we have a chance to discuss these matters further.

With all good wishes and regards.

Sincerely,

Sidney

Sidney Weinhouse, Ph.D.

June 28, 1982

Dr. Roy [illegible]
Dept. of Environmental Medicine
New York University Medical Center
New York, New York 10016

Dear Roy,

I have read the draft of the EPA guidelines related to water quality criteria and want to make the following comments.

First, I fully agree with the use of IARC criteria on pages 3-7 for "Stratification of the Weight of Evidence for Carcinogenicity". These criteria were revised somewhat at a February 1982 IARC Workshop and you will probably want to use the newer version, which you can obtain from Lorenzo Tomatis at the IARC.

Second, I seriously disagree with the premise that "negative evidence for mutagenicity would tend to call for the use of conventional toxicological method...". I am afraid that this is part of a misconception that is being perpetrated that carcinogenic agents that do not have demonstrable mutagenic activity are somehow safer than those that can be shown to be mutagenic. I believe that this logic is faulty for several reasons.

First, it assumes that conventional mutagenesis always plays a role in carcinogenesis, and yet currently the tide of research evidence is flowing the other way. Oncogene activation, disorders of differentiation, specific types of gene rearrangements, etc. are attractive alternatives that are more complex than conventional somatic mutation, and most of the current mutagenesis assays do not score for such effects. Second, negative mutagenesis assays may be "false negatives" due to failure of metabolic activation, tissue and species specificity, etc. Certain known carcinogens would probably be missed in conventional mutagenesis assay (certain nitrosamines, azo dyes, dinitrotoluene, cycasin) and yet when properly studied they are genotoxic. A new compound might be negative because it is not properly studied in terms of tissue or species metabolic activation. Third, mutagenesis assays may give false positives, or the mutagenic potency in bacterial systems may be much greater than the genotoxic effects in higher organisms. Witness the current controversey over mutagenicity and health hazhards of diesel engine emissions and nitroaromatics. Fourth, certain compounds are extremely potent carcinogens

(DES, TCDD) and yet are negative in most of the mutagenesis assays. To my knowledge there is no evidence that they show a threshold effect or a dose response curve which is qualitatively different from that of genotoxic carcinogens. Fifth, there is insufficient data to indicate that tumor promoters show threshold effects or dose-response curves that are different from complete carcinogens. Sixth, even conventional mutagens do not always show linear non-threshold dose response curves perhaps due to excision DNA repair, inducible repair, toxicity at high doses, pharmacokinetics, etc.

In general, the criteria in this draft fail to acknowledge the multistage nature of carcinogenesis and the problem of synergistic interactions between initiators, promoters and various cofactors. This considerably confounds efforts to do simple dose extrapolations. Table 2 is instructive in that it shows that mutagenicity as a practical criterion in risk extrapolation is often very irrelevant. For most of the compounds listed the evidence for mutagenicity is "inadequate" or "inconclusive"; therefore this parameter is irrelevant. Many of the compounds that pollute water sources are problematic since they are halogenated organics and we know very little about their mechanism of action. They also bioaccumulate and may show synergy with other compounds. Why is it more appropriate to use the "conventional toxicological method" for these compounds than the "linear non-threshold model"?

I trust that these comments are useful and I would be happy to discuss some of these issues with you. I can appreciate that this is a difficult area and that certain decisions must be made on the basis of existing knowledge. However, as indicated above, I disagree about some of the basic assumptions that are made in the draft of these guidelines.

Sincerely yours,

Bernie

Washington, D.C. 20460

Dear Dr. Albert:

I have read the document you provided. I consider it reasonable that EPA use the IARC guidelines on the weight-of-evidence for carcinogenicity. However, explicitly answering Part C, page 7, I am especially dubious about using mutagenicity data for quantitative cancer risk estimates as proposed on page 7. Most persons in the field would agree that the correlation between mutagenicity and carcinogenicity may vary between 60 and 90 percent depending on the structures of the compounds involved. Thus the statement that there is a correlation between carcinogenesis and mutagenesis should be motified. Furthermore, not all carcinogens interact with DNA which undermines the statement "the commonality of DNA damage for carcinogens and mutagens."

I am dubious about "the quantal nature of the interactions of chemicals with DNA" for risk analysis for certain reasons. (1) Although there may be a linear dose response between the level of DNA adducts for some specific carcinogens, for other carcinogens there are numerous DNA adducts. The significance of the various adducts is not known; thus dose-response relationships have not been determined. On Page 8 it is stated that the plausibility of the model depends heavily on the acceptance of the somatic mutation theory of cancer. I am distressed that this leaves no room for other theories of carcinogenesis and implies that one must accept this theory.

Page 10, 2nd paragraph: "the first uncertainty factor is considered to be a safety factor of 10 based on the greater certainty that the agent is carcinogenic for humans." Is it a fact that any one particular compound is more likely to be carcinogenic in humans?

On page 15, the last paragraph states: "The guidance toward the midrange with many of the compounds reflects the fact that few suspect carcinogens have been tested adequately for mutagenicity." I question this statement in view of many papers on testing large series of compounds for mutagenic activity as well as the NTP activity in this area.

Over all, therefore, I am dubious about the proposed scheme to use mutagenicity data for quantitative risk assessment.

Sincerely,

Elizabeth K. Weisburger, Ph.D.

- To add an additional safety factor of 10 for chemicals for which there are human data seems to cast doubt on the interpretation (for human disease) on those cases where there are not human data. I don't think this reasoning makes sense.

Page 13. The notion of bracketing the risk for determining water quality criteria,

10^{-15} > True risk > "conventional toxicological method"

appears to have merit - especially when combined with the product of some expert judgment in each case.

General comments

This paper proposes a rationale and a methodology for a semi-quantitative estimation of the liklihood that a given chemical species will contribute to human cancer burden. It conforms to the earlier EPA guidelines for estimating cancer risks which permits "quantitative estimation of incremental cancer risks..." The proposal implies that graded or differential responses to chemical exposures might be expected as a function of whether or not the chemical acts directly upon the genetic material of the target cells.

The proposal rests on the present understanding of biological mechanisms of cancer causation [illegible] empirical evidence and a theoretical framework. Specifically, it is proposed that the implications for human biology are substantially different (measured as probability of initiating neoplastic disease) for chemicals which induce gene mutations and those which do not and that it is possible to distinguish between these two classes.

The general idea expressed in this paper has merit. There is evidence for this biological distinction. Further, the specific proposal in this paper suggests a decision pattern to accomodate this distinction that includes a number of desirable features considering the present state of understanding:

1. It permits a substantial degree of flexibility.
2. It accomodates or even invites professional or expert judgment.
3. It remains essentially conservative - perhaps even too conservative (see below).
4. It proposes to display a range of estimates of risk in each case (extrapolation from a linear hypothesis model to that derived from "conventional toxicological method").
5. It would express the risk estimates in probabilistic terms.

Specific comments

Page 7. The proposed change in wording from the original IARC text amounts to a substantial change in meaning. I would suggest retaining the original text.

Page 9. I would argue that a scientifically better mode of conversion of results from animal to man would be on a surface area basis rather than a body weight basis.

Page 10. The author proposes that, in general, humans are more sensitive to chemical carcinogens than are other species. I am not aware that this is "generally" true.

Roy E. Albert, M.D.
Carcinogen Assessment Group
Office of Environmental Assessment
US-EPA
Washington, D.C. 20460

Dear Dr. Albert:

Thank you for the opportunity to comment on the draft proposed addendum to US-EPA guidelines for assessing carcinogens in water. It is encouraging to note that the guidelines are attempting to consider a broad spectrum of data including mechanistic information for risk assessment analysis. We would continue to encourage the use of all appropriate data on any given chemical in conjunction with sound scientific principles. Meeting that objective dictates that an even more scientifically flexible guideline than currently proposed should be considered. Several individuals (C. Park, R. Reitz, and P. Watanabe) with background in biostatistics/modeling, toxicology/pharmacology and biochemistry have commented on the current proposal.

Once again thank you for the opportunity to review the document and we hope that the suggestions will be useful.

Sincerely,

P J Gehring

AN OPERATING UNIT OF THE DOW CHEMICAL COMPANY

GENERAL COMMENTS

While the document attempts to incorporate more flexibility in the standard setting process it is still too rigid and falls short of the goal of using all of the available scientific data to make the best scientific decision. The fact that none of the chemicals cited in Table 2 are characterized as nonmutagenic when considerable scientific evidence exist on some to support non-mutagenicity is a reflection of the use of inappropriate criteria. Furthermore, the use of inflexible presdesignated safety fact does not allow for scientific judgement based on the abunda or lack of available data. The selection of mathematical models should be based on scientific data of goodness of fit without disguised conservative factors such as 95% confidence limits on slope and assumed linearity at low doses. The best scientific estimate is seldom, if ever, accurately reflected by hidden conservative assumptions. The guidelines need modification such that the best science can be used and that better data is rewarded.

SPECIFIC COMMENTS

Criteria for genotoxicity (gene mutation)

The criteria for adequate or sufficient evidence for gene mutation being positive results in any two systems (one being eukaryotic) is inappropriate. More scientific flexibility is required for assessing sufficient evidence of gene mutational activity. The variable nature of results from the current *in vitro* mutagenicity tests do not support this rigid criteria. For example, chloroform was selected by the National Toxicology Program (NTP) as a "model" compound and was subjected to an extensive battery of mammalian and bacterial mutagenicity tests (Bridges et al., Progress in Mutation Research (1981), 1, 49-67; Brookes and Preston, loc. cit.) The conclusion from the NTP studies was that chloroform was not mutagenic. In spite of the extensive testing the current guidelines categorize the evidence for chloroform as "inconclusive".

Furthermore, none of the compounds listed in Table 2 are listed as "negative" although many of them have been extensively tested in short term tests with predominantly negative results. Another obvious inconsistency is characterizing benzene as unequivocally mutagenic. The mutagenicity data for benzene do not support this.

Creation of a new regulatory class of carcinogens without apparent mutagenic activity will have little consequence if it is impos[illegible]sh that any compounds actually belong in this class with state of the art experimentation. Those chemicals which are uniformly active in mutagenicity tests (certain nitrosamines, aromatic amines, PAH and alkyl epoxides) are examples of chemicals which should be classified as having sufficient evidence of mutagenicity. Those with predominantly negative results with weak or inconsistent positive tests are likely negative and should be characterized as such (exp. chloroform, DDT, benzene, carbon tetrachloride, etc.). Therefore it is suggested that a more flexible guideline and judicious scientific evaluation be given to the criteria.

Animal/Man Extrapolation

The animal to man conversion should be separated from the mechanism question. The proposed guidelines have mixed the two and made the procedure more conservative. We suggest calculating the 10^{-5} risk; the safety factor approach, and the midrange, then selecting the "best" number and then converting estimates from animal to man using whatever conversion is scientifically appropriate. The present midrange is the geometric mean of the two estimates; but one estimate is a mg/cm^2 conversion while the other is a mg/kg conversion.

The selection of the geometric mean as opposed to arithmetic mean is a policy decision favoring the conservative side rather than a scientific estimate. The arithmetic mean is preferred.

Statistical Models

The language is somewhat argumentative in places; particularly with respect to the linear model: the "plausiblity" of the linear model (p. 2); the implication that the linear model represents a reasonable biological mechanism (p. 8). The "scientific acceptance" of the linear model is certainly detabable. Furthermore, on page 7 (last line) ". . . linearity at low dose levels is a part of the model." This is very misleading. The multistage model does not have any assumption of linearity. Kenny Crump, under an EPA contract, developed a statistical method for incorporating an upper confidence on the linear term. His procedure forces a linear term regardless of the data, but this is not part of the multistage model. It was a policy decision, not a scientific one, to incorporate a linear component and modify the multistage model. It is important to separate policy from science and identify each accordingly.

Furthermore, the above comments on animal to man extrapolation after derivation of level/risk should be dictated by knowledge of the mechanism of toxic action (pharmacokinetics) of the chemical. Man will not always be more sensitive than rodents and this should be considered in the process of species extrapolation.

Selection of Safety Factors

The imposition of a rigid 1000x safety factor (to be applied to the extrapolated 10% effect level) does not allow the flexibility in scientific judgement needed when cancer is induced primarily as a result of nongentoxic mechanisms. In practice, use of this safety factor amounts to linear extrapolation to a risk of 10^{-4}. This is only 10 fold less than that proposed for use with DNA damaging agents (where a 10^{-5} risk level is used). When good evidence exists that a material is carcinogenic only at toxic levels, and non-toxic levels are well established, the selection of other safety factors should not be precluded by an arbitrary value of 1000.

Classification of Animal and Human Studies

The classification of negative studies into the "inadequate" category is misleading. A well conducted animal study characterizing effect and no-observed-effect doses is not "inadequate"; it is negative and should be characterized as such. Furthermore, well conducted epidemiology studies in conjunction with well conducted animal studies yields good evidence of the lack of any significant carcinogenic potential and should not be categorized as "possibly carcinogenic". A more acceptable compromising phrase would be "no evidence of potential carcinogenicity".

Table 2

The concentration estimate for TCDD should be rechecked. We could not duplicate this value. Other derived values are based on the absolutely worst [illegible] ose possible) regardless of other data. The most sensitive study should often be used but there should be considerable scientific judgement exercised in the selection process.

Groups of Chemicals (p. 6)

Groups of chemicals should be used only when data on all exist to support potential carcinogenic risk. The use of structural analogy is not supportable. Examples such as 2,4-toluenediamine (positive animal carcinogenicity) vs 2,6-toluenediamine (negative animal carcinogenicity) are too numerous to substantiate the use of structural similarity in regulatory decision making.

Policy Options

Number 3 on a single number versus a range with guidelines. This option appears worthy of much more thought as a viable alternative.

First of all, any evaluation of risk is complex and EPA should back and be responsible for the best judgement of risk. Either grided uncertainty factors, or case-by-case assessment of uncertainty factors on judgment are less arbitrary than the generic 1000 fold factor or the endpoint of a specified risk level.

Number 4 on the risk level. If this alternative is left in the document, emphasis should be placed on the fact that the linear multi-stage/model is an upper limit value, and that even a solely genotoxic substance is highly likely to present a much lower risk.

Dear Roy:

As I mentioned to you last week, I am sorry about the delay in responding; however, things have been a bit tight recently. I appreciate the opportunity to review the document entitled, "Additional U.S. Environmental Protection Agency Guidance for the Health Assessment of Suspect Carcinogens with Specific Reference to Water Quality Criteria." My comments are attached for your consideration.

Sincerely,

Ronald W. Hart, Ph.D.
Director, NCTR

ADDITIONAL U.S. ENVIRONMENTAL PROTECTION AGENCY GUIDANCE FOR THE HEALTH ASSESSMENT OF SUSPECT CARCINOGENS WITH SPECIFIC REFERENCE TO WATER QUALITY CRITERIA

Comments by:

Ronald W. Hart, Ph.D., Director, NCTR

A. General Comments

1. This document appears to base the plausibility of linear extrapolation on the mutagenicity of a carcinogen. This may represent an argument for low dose linearity, but it may not be necessary or even the major argument. Approximately one new cancer case occurs in the U.S. every minute. Thus, at any given instant there are a number of individuals who have a carcinogenic body burden insult which is almost adequate to initiate or promote a particular carcinogenic process. When a chemical carcinogen is introduced into an individual's environment, it may not enter as an increase above a zero dose but as an increase to an already existing carcinogenic exposure. If this already existing level of exposures is producing cancers, the detoxification/modulator processes are either already overloaded or circumvented. If the addition of a carcinogen adds to the existing level of exposure, then an additional increase in a particular cancer incidence may result. Regardless of the shape of the dose response curve, a short segment of this curve (corresponding to a small increase in dose) may be able to be approximated by a straight line (see Figure). This so-called theory of "background additivity" predicts low dose linearity of carcinogenic processes quite apart from mutagenicity. Thus, while the correlation between mutagenicity and carcinogenicity is sufficient to justify the use of mutagenicity data in assessing a potential carcinogen, it is not strong enough to imply that somatic mutation is the proven mechanism of carcinogenesis and that the linearity of carcinogenesis with respect to dose is dependent exclusively on

knowledge of that mechanism. Further, at this time there may be enough dose-response studies with [illegible] to support the linear extrapolation model without evoking mutagenesis as the sole basis for the mechanism.

Finally, as noted in [illegible], even though mathematical models may fit in the experimental dose range, they can not be used for low dose extrapolation because of wide discrepancies that appear at low doses. Point or best estimates can not be obtained without knowing the exact dose response model. Since the true model can not be obtained from bioassay data, all that can be accomplished is to consider the uncertainties in risk assessments. If the dose response is curving upward, linear extrapolation below the experimental dose range provides an upper limit on risk. This should be able to be accomplished with bioassay data alone and develops an argument independent of, but enhanced by mutagenicity data.

2. While it appears reasonable to use the confidence limits from the linear multistage model as one means for arriving at "safe" exposure levels for an animal population, it might also be reasonable to include some reference to the relative sensitivities of humans and test animals as a final step.

The conventional toxicological approach discussed on page 9 should be better defined, delineated or referenced, as should the mathematical procedures used for dose extrapolation.

Further, it may well be the case that this so-called conventional toxicologic approach gives essentially the same answer as the linear multistage model if it is also tied to the same level of risk, as it should be. The advantage of the so-called conventional toxicologic approach is that it is very simple and akin to conventional procedures. It should be cited that estimating a low dose response level, e.g. the 10% response level, and extrapolating linearly below that point has been proposed by Van Ryzin

J. Occup. Med. 22, 1980) and by Farmer, Kodell, and Gaylor (Risk Analysis 2, 1982) except that they suggested using the 1% response level.

Also, can one really call this approach a conventional toxicologic approach, which is based on the no-observed-effect-level (NOEL). Even if the NOEL exists, it has no precise meaning because it depends on the number of animals tested and hence provides a different level of risk in each case. Since the proposed technique selects a given response level (10%) and then applies an uncertainty (safety) factor, would it not be more proper to call this approach a "safety factor procedure" or "low dose linear extrapolation", since the two are almost identical.

3. The argument in paragraph 2 on page 10 is not logical. In the previous paragraph, a factor of 10 was imposed because of the uncertainty of sensitivity of humans. If then the data are available in humans (and presumedly their sensitivity is then known), one can not justify the use of the same uncertainty factor because you now have a greater certainty. If one is uncomfortable with only a factor of 100 when the data are presumedly more reliable, then the safety factor in less certain cases should be reevaluated. Therefore, the two paragraphs at the top of page 10 could, if you like, be replaced by the following paragraph:

> If the dose response curves upward, reducing the dose by an uncertainty factor of F will reduce the risk by at least a factor of F. Thus, starting at the dose that gives a 10% response, dividing by an uncertainty factor of 10,000 should reduce the risk to below one in 100,000. If the extrapolation is based on animal rather than human data, an additional factor may be employed depending upon the relative sensitivity of humans to animals.

3. Page 8, paragraph 2, line 2. Change "to use" to read "a modification of"; line 6, change "conventional toxicological" to read "modified".

4. Page 9, paragraph 2, line 1. Change "the conventional" to read "a modified"; line 2, delete "for an added refinement of making", replace with "which makes"; line 9, after "...tumorigenic responses." add the following sentence, "Also, NOEL has no definition and is a statistical result which depends on the number of animals tested." Line 14, after "....is recommended", insert "to estimate the 10% response level"; line 16 after "....upper confidence limit.", delete period, insert "on the response."

5. Page 10, delete paragraphs 1 and 2. Please see General Comments, above.

6. Page 12, sub-paragraph D, line 6, delete "In order to incorporate evidence for mutagenicity.", begin new sentence, "It is....."; line 7, change "both" to read "either", change "and" to read "or", change "conventional" to read "modified"; line 8, delete "a range of"; line 9, change "conventional" to read "modified". The two approaches are nearly the same when a risk level of 10^{-5} is specified for both.

7. The modified exposure limit needs to be tied to risk. It is difficult to provide an exposure limit without any notion of the degree of protection that it might provide.

8. Page 13, first paragraph. Delete last sentence: "It is proposed...... ....toxicological method."; second paragraph, delete all of the paragraph down to last sentence, "Such guidance, together....". As was stated above, one could divorce the process from mutagenicity and use other reasons for low dose linearity.

9. Page 13, sub-paragraph E, line 1. Change "could" to "should". Reference

last sentence of paragraph No. 1 - Why shouldn't they be employed? Can we be so comfortable with best estimates that we don't need to allow for sampling errors and experimental variability?

Dear Roy:

I read with interest your proposed risk estimation procedure. I am basically sympathetic with your concern over the various possible mechanisms of carcinogenesis and how they should be treated from the standpoint of low-dose estimation. Basically you are breaking out those compounds which are not gene mutagens and applying a type of safety-factor approach to them. In general, I find the use of safety-factors to be quite unreliable and very ad hoc as I tried to explain in the attached manuscript.

Specific problems I have with your approach are as follows:

(1) You assume the dose-response function for carcinogenesis is quite different (i.e. non-linear) when the chemical does not cause gene mutations. The philosophy that we took in Hoel et al. 1975 (enclosed) is that for these cases we assume that a linear function is a reasonable upper bound to the dose-response function. If we actually understand something for these cases we should then use the information. The question then is how different from linearity are your non-gene mutagens? I do not believe you have any real idea except possibly in a few specific cases.

(2) If a material is positive in one assay for gene mutation and the result is quite reproducible why do you require a second type of assay? This seems biased in the direction of minimizing your false positives at the expense of greatly increasing your false negatives. I am convinced that an Ames positive rodent carcinogen should be assumed to behave linearly at low dose after kinetic adjustments have been made.

(3) The safety factor of 1000 applied to an estimated 10% response is equivalent to extrapolating linearly to a risk level of 10^{-4} (with the confidence interval and species factor dropped). Since you usually

apply a confidence interval plus a species difference by surface area I would expect the two methods to differ by a factor of 100-500 (using 10^{-5} for the linear extrapolation) which is what your examples generally showed. Since you are using linear extrapolation and are, I believe, not assuming thresholds, why not simply state that you use 10^{-4} instead of clouding the issue with safety factor statements.

(4) You should be prepared to defend the possibility that 10 non-mutagens which are carcinogenic and linear could yield a total risk of $10 \times 10^{-4} \times 10 = 10^{-2}$ if a species factor of about 10 is reasonable (NAS Safe Drinking Water Report, Volume 3, page 49, for an argument for surface area).

From these comments you see that I am fairly negative with regard to "cookbook" approaches. What I would do is as follows. Take each compound on a case by case basis and argue away from linearity if the data warrants it. This would include pharmacokinetic considerations, short term test results, shape of the carcinogenesis dose-response curve and speculation on the mechanism. For this information, try to estimate the low-dose effect in man and use whatever level of risk the EPA is politically satisfied with.

We should sit down next week and discuss this issue further since I believe your objectives are correct.

Best wishes,

David G. Hoel

David G. Hoel, Ph.D.

COMMENTS ON U.S. ENVIRONMENTAL PROTECTION AGENCY GUIDELINES FOR THE HEALTH ASSESSMENT OF SUSPECT CARCINOGENS WITH SPECIFIC REFERENCE TO WATER QUALITY CRITERIA

by John Higginson, M.D.
Universities Associated for Research and
Education in Pathology, Inc.
9650 Rockville Pike
Bethesda, Maryland 20814

Introduction:

In general, I find this document represents considerable improvements on previous efforts to provide guidelines for the health assessment of suspected carcinogens. This is due partly to increased emphasis on the "weight of the evidence" approach, and partly to the recognition that modern concepts of the nature of carcinogenic mechanisms have significant implications for regulation.

General Comments:

The following points appear of major significance.

1. While it is widely accepted that there is a no-threshold for all genotoxic carcinogens, this concept lacks scientific proof. In fact, as the complexities of mechanisms become better understood, as does the nature of DNA repair [illegible] of certain steps in carcinogenesis, many scientists believe that an operational threshold probably exists at least for certain genotoxic agents. At least mentioning this possibility may avoid criticism that the report still implies that one molecule of a genotoxic agent may carry a potential risk of cancer. In this sense the term "potential" is meaningless.

2. Conversely, however, it has still not been shown conclusively that all non-genotoxic carcinogens or cancer inducing agents necessarily have a threshold, although this may be true. Both the epidemiological and experimental data are limited. Further, this group represents a wide range of agents, operating through a variety of different often unknown mechanisms, so that it is not possible to classify such agents generically. Thus, I would make a distinction between DES or conjugated estrogens, which are strong promoters, and for operational purposes, can be regarded as carcinogens and such non-specific cancer enhancing agents as sucrose, etc. While a number of these non-specific agents may be found in water, they are probably of little significance since the levels are too low for practical consideration. However, for consistency in guidelines, their existence should be noted. This would suggest that non-genotoxic cancer inducing agents be considered on an ad hoc rather than on a generic basis.

3. There is considerable evidence that mutagenic and carcinogenic potencies are not equivalent. False positives with mutagens have been reported. Damage to DNA is not the equivalent of carcinogenesis, and I think there is increasing support for the view that significant genetic damage is necessary for transformation as opposed to a single point mutation. Thus, the text should at least leave open the view that genotoxic agents may not necessarily act through simple somatic mutations, but that carcinogenesis may be triggered by carcinogens through other mechanisms, e.g. transposition, oncogenes, etc. Accordingly, it should be noted that there are scientific limitations to accepting mutagenic tests as invariably indicating genotoxicity in terms of carcinogenesis.

4. It is most important to avoid the impression that genotoxic agents are "bad" carcinogens, and non-genotoxiic agents "good" carcinogens. Thus, some of the latter may be strong cancer inducing agents in the sense of DES, estrogens and possibly asbestos, whereas certain other genotoxic carcinogens may be so weak as to be non-carcinogenic for practical purposes.

The above comments do not mean that I believe there are no differences in the nature of genotoxic and non-genotoxic agents from both a biological and operational viewpoint, nor that there are not important differences in considering thresholds, differing types of agents. From an operational viewpoint, I believe the distinction is desirable and justifiable. I also believe that the scientific differences require more elucidation and should not depend only on mutagenic testing.

5. Biomathematical modeling: I believe it is desirable to emphasize that nearly all biomathematical modeling is used for operational convenience or to stimulate research hypotheses due to the absence of biological data. They are never to be regarded as substitutes for data in the real world. Thus, whereas there may be considerable rationale for using linear, non-threshold models within a species, for extrapolation of dose responses, there are considerable scientific limitations regar[illegible] such models for extrapolation between species, whether [illegible] toxic or non-genotoxic agents, in view of the many unknown or unmeasured parameters involved. The data are simply not there. Further, the choice of the models still remains subjective and, as pointed out in the guidelines, is dependent on the individual's views of the mechanisms involved. The rationale, I believe, for using such models for non-genotoxic cancer inducing agents is even less strong than for genotoxic agents, in view of the many possible mechanisms that may be involved. The distinction between a simple arbitrary safety factor and a biomathematical model may falsely give the impression of a non-scientific versus a scientific approach that is not the case. The fact that models are extensively used adds nothing to their scientific validity as they have not been adequately tested.

Specific Comments:

Page 2, Section 1:

The term "formal approach": I think a tentative formal approach would be more desirable terminology, as implying uncertainty and indicating that approaches may change as new information becomes available.

Page 2, Section 2

In addition to taking mutagenecity into account in quantitative risk assessment, would it not be worthwhile to add a phrase such as "any other metabolic reaction that may be pertinent to initiation", i.e. comparative carcinogen metabolism between species, Thus, pivotal differences between activating and inactivating enzymes, for example, may be identified, which may be very pertinent in quantitation of risks. This approach may become increasingly important in the future, if not widely used at present.

Page 3:

I am in agreement on the value of the IARC approach, which is based on collective judgement of experts. However, as you have pointed out, it is possible that much of the IARC's value depends on the fact that Lyon is over 3000 miles from Washington and its staff and workshop participants are divorced from non-scientific pressures. The IARC does not exist to help regulatory agencies, but to provide, generate and evaluate scientific data.

I should point out that there has been one criticism of the IARC guidelines which your group might wish to consider. That is in relation to inadequate or negative data. Thus, there are some scientists who believe that the IARC criteria are weighed against negative studies to emphasize only the positive. Thus, many negative studies are never published or evaluated. There is also a tendency to ignore essentially negative epidemiological studies, since these can never completely prove the negative, a limitation incidentally which is also applied to the study of weak carcinogens in animals. A notable exception is the report on fluoride in water. Thus, under certain circumstances, the negative data in humans may be quite considerable and sufficient to exclude a substantial risk to man at levels of past exposures, although insufficient "to exclude a minimal or non-detectable risk". Further, the data may indicate the absence of a human risk, but it may again be insufficient to exclude a minimal risk. I believe this qualification, in practice, may be important especially when [illegible]luating non-gentoxic agents and providing backup data for mathemati[illegible]polation.

Page 7:

My comment here relates to quantitiative risk estimation with respect to mutagenicity. In general, it has been agreed that with ionizing radiation it may be possible to calculate approximately the "target cell" dose. Our lack of knowledge of the modifications that occur in chemical carcinogens as a result of digestion, absorption, deactivation and inactivation, etc. is such as not to permit any estimates of target cell doses in man. This was the conclusion of a group meeting in Stockholm under Cedelof in 1979. I believe that this distinction between ionizing radiation and chemical carcinogenesis should be mentioned when discussing linear non-threshold extrapolation models. This would leave open the possibility of developing better methods of estimating target cell doses (DNA adducts). If cell markers can be identified in the future they should be used rather than exposure levels for modeling.

Page 8:

I find this page useful in that it does emphasize the importance of carcinogenic theory in terms of evaluation of carcinogens and the attempt to classify them into "genotoxic" and "non-genotoxic". I still believe this to be desirable if scientifically imperfect. I would, however, like to suggest that a further paragraph be inserted on page 8 regarding the "non-mutagenic" or "non-genotoxic" carcinogens. There is some evidence that the latter may fall into two groups. The former includes promoters and other non-genotoxic agents, e.g. estrogens, which may have a specific effect and as such be identified for operational purposes as carcinogens, even if the mechanisms are unknown. However, there are a certain number of non-specific agents, such as sucrose, unsaturated fat, etc., which under certain experimental circumstances induce cancer and cannot be readily distinguished from classical promoters. These theoretically could be called "carcinogens", but I think this would give rise to confusion among the public. It may be advisable, therefore, to give further consideration to the definition of carcinogen as used in the addendum, and to distinguish such agents from non-specific cancer inducers such as sucrose, unsaturated fat, etc. This will avoid the danger of inconsistency in distinguishing between specific and non-specific cancer inducing agents.

Page 9:

In principle, I am in agreement with the approach on this page and on page 10 regarding the principle of uncertainty factors. However, I believe that the argument needs some clarification. Should one not consider the possibility now of having two levels of uncertainty, firstly an arbitrary scale where no data are available and a second scale where certain factors can be considered and given numerical values. Thus, in the case of vinyl chloride the difference between the metabolism in the human and the rat liver has been put forward as an explanation for the different sensitivity of the two strains. Would it not be worthwhile to emphasize the fact that this approach may be increasingly practical in the future? In dealing with "non-mutagenic" carcinogens, are we yet in a position to say that they cause irreversible lesions? Certainly not in the early stages if we include promoters as carcinogens. Thus, to justify an additional safety factor based on the grounds that cancer is irreversible without more knowledge of mechanisms of the particular agent accordingly appears somewhat illogical. If such a safety factor should be added, this should be on the grounds of cancer rather than on a biological principle.

Page 11.

Page 11 raises the old problem that any gene mutation is always regarded as indicative of carcinogenic potential. A wide range of gene mutations may be produced by mutagens but those essential for carcinogenesis are unknown. I also think it worthwhile at some point on this page to mention more recent views regarding mechanisms of carcinogenesis depending on the transposition, oncogenes, etc.

In Conclusion:

I believe the guidelines represent a reasonable attempt to improve quantitative risk assessment through better use of scientific knowledge. As one who is not personally concerned in regulation, I recognize the dangers of overemphasizing the lack of scientific data and its uncertainty as leading to excessively restricting caution or a "do nothing" attitude. It is, therefore, desirable to accept imperfect conclusions for operational purposes although not scientifically proven. However, the guideline should be sufficiently flexible to allow modification in the light of new data without needing to be rewritten.

To the Individuals on the Attached List:

Thanks for your very worthwhile comments on the EPA draft document: "Additional U.S. Environmental Protection Agency Guidance for the Health Assessment of Suspect Carcinogens with Specific Reference to Water Quality Criteria".

The roster of people who commented is enclosed. I think that you will agree that the group is as balanced and competent as one could hope to get. Copies of the responses are also enclosed.

The use of the IARC criteria for stratifying the weight of evidence for carcinogens was strongly supported; there were no dissenters. Of the 12 commenters that addressed the issue directly, all were essentially in favor. However, there were provisos that more attention be paid to negative evidence and that Group 3 not be designated as "possible carcinogens" but as agents for which no decision on carcinogenicity could be made, i.e., the original IARC language.

It is probable that the EPA could adopt the IARC approach without serious scientific opposition. Such a move may have a significant regulatory impact since agents classified under Group 3 would probably have less regulatory impetus then those in Groups 1 and 2.

The quantitative issue of distinguishing between mutagenic and non-mutagenic carcinogens is more complicated and the reactions were varied. As you recall, the draft document, in general terms, used the linear non-threshold approach for mutagenic carcinogens and the more or less conventional NOEL - safety factor approach for non-mutagenic carcinogens. Nobody gave unqualified support the the approach. Half the responders (11 of 22) gave qualified encouragement: Gehring, Hoel, Higginson, Magee, J. Weisburger, Pitot, E. Miller, J. Miller, Ray (verbal), Burger, Upton. Six of the responders were negative: Saffiotti, Weinhouse, Nelson, Perera, Weinstein, Hart. Four of the responders were non-committal: E. Weisburger, Neal, Tomatis,

SESQUI
CENTEN
NIAL 1831
CELE 1981
BRATION

McClellan. The negative responders felt that the tests for distinguishing mutagenic from non-mutagenic carcinogens were not certain and even if they were, there is insufficient biological basis to treat mutagenic and non-mutagenic carcinogens differently. The negative responders would generally prefer the linear non-threshold extrapolation model to be used for both mutagenic and non-mutagenic carcinogens. Weinhouse, alone, is flatly opposed to quantitation; he is also opposed to the conventional NOEL - safety factor approach. Lewis is for the NOEL - safety factor approach for both mutagenic and non-mutagenic carcinogens.

My own attitude toward the regulatory distinction between mutagenic and non-mutagenic carcinogens is guarded. However, since there has been so much talk about the matter, it seemed appropriate to give the proposition a trial. Although it elicited some resounding Bronx cheers, there were a number of eminent scientists who think there is enough substance to the distinction to warrant pursuing the matter further. The comments point out the way to do this; namely, to include mutagenicity as one of a number of factors in making regulatory distinctions amongst carcinogens. In this regard, there were many comments to the effect that the approach needed more flexibility in terms of pharmacokinetics, evidence for reversibility as with promoters, DNA repair, target dose, etc.

As a procedural matter, both Hoel and Hart pointed out that the NOEL approach of applying a safety factor to a specified level of carcinogenic response is the same as using the linear non-threshold extrapolation model to determine the dose which is equivalent to a specified target level of risk. For example, the application of a safety factor of 1000 to a response level of 10% is the same as a linear extrapolation to a target risk of 10^{-4}. Hence there is no need to use different methods since they are interchangable by adjusting safety factors and target risk levels.

One possible approach to a revision that might accommodate the above comments, in the case of the water quality criteria, would be to use the linear extrapolation model to identify the concentrations equivalent to various target risk levels, (e.g., 10^{-7}, 10^{-6}, 10^{-5}, 10^{-4}) and to present guidance as to which range might be given greatest weight in the formulation of water quality standards. Standard setting would involve such guidance together with a consideration of all the practical concerns that go into such judgements, such as technical and economic feasibility. The recommendation as to the appropriate target range of risk would be based not only on mutagenicity but all of the above mentioned factors as well as any other scientific considerations that are relevant at the time. The argument would be that the linear extrapolation model provides only an upper limit to the risk estimate and that at the recommended concentration range the risks are believed to be significantly less than the indicated levels.

Any further reactions you might have would be welcomed. We will let you known how things develope.

Thanks again for your help.

Dear Betty:

I have reviewed the paper sent to us on June 28 entitled "Additional U.S. Environmental Protection Agency Guidance for the Health Assessment of Suspect Carcinogens with Specific References to Water Quality Criteria" as your office requested. I have enclosed a series of comments which you may find useful.

Thank you for permitting us to review this interesting paper.

Sincerely,

Edward J. Burger, Jr., M.D., Sc.D.
Director

OFFICE OF
POLICY AND RESOURCE MANAGEMENT

SUBJECT: Toxics Integration Task Force

FROM: Richard D. Morgenstern, Director
Office of Policy Analysis

TO: Assistant Administrators
Associate Administrators
Acting Regional Administrator, Region III

Attached is an Agenda for the first meeting of the Toxics Integration Task Force, and a statement of the issues that I discussed with you this week.

The Agenda is self-explanatory; if you have any comments please let me know. The issues statement summarizes our understanding of what Al Alm wants the Task Force to address, and includes a few suggestions on how we might proceed from here. It basically expands on the issues that came out of a meeting we had with Alm last week; I have attached the talking points from that meeting for your reference.

During the first meeting next Wednesday (Room 1109, West Tower, 10:00 AM) I hope we can reach agreement on:

1. A limited number of topics on which we can promise useful products to the Administrator;

2. Subcommittee assignments: who shall lead on each topic, and who else shall participate; and

3. General modes of approach for each topic area.

Director
Office of Toxic Substances

AGENDA

Toxics Integration Task Force
June 22, 1983
10:00 AM to 12:00 PM

Review of Agenda and Schedule — Dick Morgenstern

Discussion of Issues and Decisions on Assignments
(15 minutes each)

A.1 Consistency in risk assessment
  - Problem definition
  - Goals and products
  - Proposed approach
  - Assignments

A.2 Consistency in risk management
  - Problem definition
  - Goals and products
  - Proposed approach
  - Assignments

B.1 High-visibility chemicals
  - Problem definition
  - Goals and products
  - Proposed approach
  - Assignments

B.2 Intermedia inconsistencies
  - Problem definition
  - Goals and products
  - Proposed approach
  - Assignments

C. Interagency coordination
  - Problem definition
  - Goals and products
  - Proposed approach
  - Assignments

C. Options for inter-agency coordination

Historic paper exists on this area

Problem statement: In many instances, whether EPA is planning to regulate a chemical or an industry source, the Agency's mandate may cover only a fraction of the overall risk associated with the pollutants in question. Other agencies, notably OSHA, CPSC, and FDA, may have equal or larger responsibilities through their control of occupational exposure, consumer products, and foods. Without coordination among these agencies, it is not likely that the Federal government will propose either complete or efficient regulation.

Questions:

What is broken?
What needs to fixed?

(a) How serious is this problem? Is it confined to a few chemicals or industries, or is it pervasive?
(b) If a consortium of federal regulators to coordinate the activities of the various agencies were established, what agencies should participate?
(c) On what specific areas (information collection, risk assessment, risk management, regulatory development, etc.) should the group concentrate its efforts?
(d) How can the question of leadership be resolved?
(e) How much authority should this consortium have?

Possible approaches (sequential, not mutually exclusive):

Yes

(a) Study of the history, successes, and failures of the Interagency Regulatory Liaison Group.
(b) Design alternative institutional structures for an interagency consortium to coordinate toxics-related activities; analyze advantages and disadvantages of each.
(c) Recommend a specific plan for establishing the consortium:
    - propose members
    - draft charter

To be decided at first meeting:

Scope of issue: is the problem of interagency coordination serious enough to merit establishment of an interagency consortium on toxics?

Are there any plausible alternatives to an interagency group?

MOUs?

How should the Task Force deal with other Agencies, if at all, during its investigation of this issue?

Subcommittee assignment, as appropriate.

UNITED STATES ENVIRONMENTAL PROTECTION AGENCY

JUL 01 1983

SUBJECT: Work Plan for the Toxics Integration Task Force, Sub-Ta[illegible] Group on Risk Assessment

FROM: Elizabeth L. Anderson
Director
Office of Health and Environmental Assessment (RD-689)

TO: Richard D. Morgenstern
Director
Office of Policy Analysis (PM-221)

The task group met on June 28, 1983, and agreed to the following work plan.

I. The task group identified four main areas which need addressing:

1. Guidelines development for health and exposure assessment.
2. Procedures for ensuring consistency and technical competence in the Agency's health and exposure assessments.
3. A process for updating health assessments on which the program offices rely in their rulemaking processes. (Currently, the Agency has a process for updating the Ambient Air Quality Criteria Documents, but this is not the case for any other health assessment documents.)
4. Approaches to ensure that testing protocols to generate data for health risk assessments are consistent within the EPA and with other agencies.

II. Problem identification, work assignments, and schedules:

1. First priority will be given to the topic of guidelines development. The task group identified areas for potential guidelines development and a lead person was assigned to each area:

Carcinogen Risk Assessment	Robert McGaughy
Mutagenicity Risk Assessment	Peter Voytek Jack Fowle

CONCURRENCES

SYMBOL								
SURNAME								
DATE								

EPA Form 1320-6 (12-70)

OFFICIAL FILE COPY

Reproductive Effects Risk Assessment	Peter Voytek Carol Sakai
Other Chronic Effects Guidelines	Jerry Stara Irv Baumel
Complete Mixture Methodology	Jerry Stara
Exposure Assessment Guidelines	Jim Falco

Each EPA office representative will submit issues of concern to their office in each of these guidelines areas to the lead representative. Cross-cutting issues will be submitted to Betty Anderson. These work products are due on July 16, 1983.

At the next task group meeting, which is scheduled for July 18, 1983, the lead person for each guidelines area will present a brief report to the task group on the following:

- status report on current guideline development in EPA, other U.S. agencies and committees, and the international community
- Agency needs for further guideline development
- state-of-science on which to base further guidance (i.e., is enough known to go forward?)
- recurring scientific and regulatory issues relevant to the particular guideline area
- a suggested process to follow, as appropriate, for further guideline development
- estimated time frames for work completion

After the deliberations of the task group on July 18, 1983, the group will recommend which areas need further guidelines development to ensure consistency in the Agency's approach to health risk assessment and exposure assessment. In addition, as time permits, the task group will set priorities for these efforts, recommend a process to carry out the development of guidelines, establish target time frames for these efforts, and recommend lead individuals to take responsibility for the process.

2. As a second priority, the working group will consider a process for ensuring consistency and technical competence in the Agency's risk assessment program. The lead person for this study is David Ziegele. Each EPA office representative will submit an issue paper on this topic to David by July 16. David will assemble the information he receives and make a report to the task group on the following issues:

    - current status

- current problems
- practical need for an organized process
- recommendations

This topic will be addressed, if time permits, at the July 18 working group meeting. Final recommendations will follow the next working group meeting to be scheduled no later than early August.

3. The topic of periodically updating important health assessments will be addressed by the working group in early August.

4. The task group believes that it is important for the Toxics Integration Task Force to address the issue of consistent protocols for collecting test data for risk assessment. The risk assessment task group, however, recommends that this topic be addressed by the Interagency Coordination Task group. Irv Baumel is preparing an issue paper on this topic.

In summary, the task group has established a work plan to define what work needs to be done to improve the Agency's risk assessment program. The task group also plans to recommend a process for completing this work in a timely fashion. It is the intent of the committee to make its final recommendations as soon as possible, and no later than the end of September, so that the necessary work can go forward.

TOXICS INTEGRATION TASK FORCE

RISK MANAGEMENT SUBCOMMITTEE (TASK A.2)

INTERIM REPORT

1. Introduction

This report summarizes the findings of Phase I of the Risk Management Subcommittee's work plan, a retrospective study of how information about risks and cost--the elements of risk management--was used in 27 recent Agency regulatory actions. It also proposes some activities suggested by these findings that would comprise Phase II of the Subcommittee's task: the development of a uniform reporting format for risk management information and the formulation of a uniform policy for managing cancer risks.

The reader should note the preliminary nature of this work: a substantial amount of data was submitted by the program office members of the subcommittee, which appears to warrant more extensive analysis, and a number of points require clarification, especially those relating to the subtleties of why a particular decision fell out the way it did.

The submitted data has been summarized and is presented here in a master matrix [Exhibit 1]. The column headings represent types of information that the subcommittee considered to be essential to any definition of risk management. The master is a condensation of the matrix the programs used in submitting data [Exhibit 2].

Although all the programs used the same matrix to report on their regulations, it is clear that the risk management form of analysis is more suitable to some programs than to others. Risk management can be variously defined. In the narrowest sense, it means deciding what to do about the results of a risk assessment. (Risk assessment itself is subject to a variety of definitions; here we follow the recent NAS Report, defining it as the characterization of potential adverse health effects of human exposure to environmental pollutants. This includes the establishment of safe levels as well as the probabilistic expression of risk used where no safe level can be set, as with carcinogens.)

In our attempt to put all the Agency's regulatory activities under a single rubric, however, we have stretched this definition. Risk management in the broader sense means: the collection and presentation of information about the impact of a pollutant (or a mixture thereof) on human health or the environment;

consideration of the uncertainty surrounding the imputation of such impact; and, consideration of alternative ameliorative actions, what is gained from them and what they cost, cost being defined as all economic and social impacts. This definition implies a balancing of values, and while it is certain that such balancing occurs at various levels in all EPA programs, it is clear from the present work that it does not conform to the same rules in all programs, nor does it always occur in ways that can be presented simply, as we have tried to do. Where we seem to show blanks in important areas of our matrix, it is important for us to determine whether the program has truly not considered a particular aspect of risk management (perhaps for good reasons) or whether the gap is an artifact of our reporting format. We intend to do this over the next few weeks and revise the present paper accordingly.

2. Preliminary findings

o There are significant variations in risk management practice across EPA programs.

We can identify at least three major distinctions among programs in this area: (1) programs based on statutes that require explicit balancing of costs and benefits, such as TSCA and FIFRA; (2) programs that, while they may calculate risks or benefits, are essentially technology-driven, such as Effluent Guidelines and NAAQS; and (3) programs that attempt to incorporate balancing judgements in various ways, but which are essentially risk-driven, such as NESHAPS, NSPS, and Superfund. In fact, all programs incorporate balancing judgements of some kind, but some do it more explicitly than others. The RCRA and Superfund programs have the most difficulty doing this in practice because they deal with complex mixtures of substances. In Superfund, moreover, risk management occurs at the site level; the headquarters staff is developing guidelines for this process.

o Different programs accept different levels of health effects evidence as prompting regulatory action.

There are a number of different systems available for ranking strength of evidence (IARC, Squires, etc.). These are not used in a consistent way. In fact, given any particular body of experimental or epidemiological data, it would be hard to predict what the Agency would do. Some differences may be justified, as, for example, the PMN program using structure activity relationships to prevent a product entering the market. Others appear idiosyncratic in our study; we want to explore this area further. An associated problem is the use of "numbers" like CAG risk estimates or Water Quality Criteria. RCRA and Superfund are especially dependent on such numbers, but there is some danger that numbers used in this way will take on a "magical" authority unjustified by their scientific provenance. There does not appear to be any Agency-wide way of assuring that risk estimators of this type are being used correctly and are updated regularly wherever they are involved in program policy-making.

- Pre- and post-regulatory risk levels, where calculated, have extremely wide ranges, both across programs and within the same program.

Although no reported action where a risk assessment was involved acted on a risk of less than 10^{-5}, there were three order of magnitude between the lowest and the highest risk reported as remaining after regulation. The marginal cost-per-cancer avoided was calculated only for one regulation; we will do likewise for the others where we have risk and cost information. On inspection, however, it seems likely that these will vary considerably as well. Naturally, there would be nothing wrong with a range this wide if it had some rational justification: cost, for example. We have no evidence for this as yet, but it is an important problem and deserves further analysis.

In a subsidiary study, (Exhibit III) we investigated the handling of the risk assessments for three chemicals of concern (mercury, endrin, and TCE) across different programs. There appear to be substantial differences in the acceptable daily intakes established by different programs for the same chemical. We intend to expand this analysis to include both more substances and other aspects of risk management.

- The attention paid to intermedia transfer of pollutants varies among programs.

There is some evidence that intermedia transfer is being considered more seriously than in the past, when it was often not considered at all. Effluent guidelines adds the costs of disposing of hazardous sludges to its control cost estimates. RCRA is concerned with waste dumps as a source of air pollution. TSCA typically examines all media in which a chemical appears. Despite this interest, in most cases in this study where tranfer occurred it was considered "not relevant." These may have been reasonable judgements, but we cannot be sure of this given the data on hand. The Agency has no general rules or standards concerning the management of intermedia transfer against which we could measure the adequacy of such judgements.

- Costs-benefit and cost-effectiveness analysis are performed differently in different programs.

The NAAQS program may not consider costs, by statute, although they report that a cost-benefit study has been done for the particulates NAAQS. The RCRA and Superfund programs did not report cost calculations for the regulations covered, although Superfund did submit site-specific reports for three sites in which costs and risks were considered and compared, although differently at each site. There is no common way of expressing the benefit of particular regulatory programs, and thus no way to insure that the array of risks the Agency is managing at any particular time includes the most serious ones.

3. Phase II Products

If more uniform risk management is a desireable goal, these preliminary results suggest some ways of approaching it. It seems clear that whatever risk management techniques are appropriate to a particular program (and these may legitimately vary) there should be a uniform way of reporting and recording these decisions. We should use the experience of preparing the Phase I report to develop formats for uniform presentation of risk management information, including uniform rules for calculating and expressing exposure, intermedia transfer, benefits and costs of regulation, to Steering Committee and the Administrator.

Beyond reporting, there remains the question of unifying policy toward the endpoint that appears to be of most concern in this area, cancer. The Agency attempted to develop a cancer policy in 1981 and much of that work will still be useful. That study was carried out by a group at the division-director level, reporting to the Toxic Substances Policy Committee, an office-director level body. The cancer policy group attempted, as a first step to set some *de minimis* level for cancer risk and reached agreement on 10^{-6}. More difficult was the problem of how to handle maximum individual risks; the Agency has always had difficulty in situations where high risks that are expensive to control affect a small number of people. The group did not reach closure on this issue.

We intend to pick up on that work and attempt to delineate what combinations of risk, certainty, and cost ought to constrain particular Agency regulatory actions with respect to carcinogens.

EXPOSURE SUMMARY

Name and Type of Regulation/ Standard/Guideline	Route	Source	Population Considered	Intermedia Transfer
Air				
Arsenic NESHAPS	Inhalation	Copper smelters; Glass Manufacturers	All U.S. w/in 20 Km. of Source	Not Considered
Benzene NESHAPS	Inhalation	Maleic Anhydride; Ethyl Benzene/Styrene	All U.S. w/in 20 Km. of Source	Not Considered
Radionuclide NESHAPS	Inhalation	DOE/NRC Licensees Facilities; Underground Uranium Mines; Elemental Phosphorous plants	Max. Exposed Ind. within 80 Km. of Source	Solid Waste collected is buried at those low-level radioactive waste sites
Particulate NAAQS	Inhalation	Numerous & diverse sources	All U.S. population	None
Water				
Iron & Steel EG	Ingestion of Water and Organisms	Aquatic Life and Drinking Water	Population surrounding ind. pt. sources	Not relevant
Copper Forming EG	Ingestion of Water and Organisms	Aquatic Life and Drinking Water	Population surrounding ind. pt. sources	Not relevant
Benzene WQC	N/A	N/A	N/A	N/A
Toxaphene WQC	N/A	N/A	N/A	N/A
Endosulfon WQC	N/A	N/A	N/A	N/A
Drinking Water				
Trihalomethane MCL	Ingestion of Drinking Water	Drinking Water Treatment Process	U.S. Pop. served by pub. water sys (80%)	Not relevant

Exposure

C-9 Aromatic Hydrocarbons (Test Rule)	Inhalation	Refueling; transport truck; solvent use	Tank truck operators; service station attendant general U.S. Pop. (self-serve gas)	Water considered
PCB Electrical Transformer Use Rule	Inhalation, Dermal, Ingestion (food, water)	Leaks & Spills from Elec. Equipment	U.S. & World workers who serve equipment	qualitative treatment
MDA (§4f, decision to regulate	Inhalation and Dermal	Workplace Air	Workers at manufacturing & processing sites (Approx. 12,000)	Not relevant
NTA (§6, decision to regulate	Ingestion of Drinking Water	Prod. releases to surface water; consumer releases to surface & ground water	Entire U.S. pop.	None expected

COST/BENEFIT ANALYSES SUMMARY

Name and Type of Regulation/ Standard/Guideline	Regulatory Alternatives Presented	Cost-Effectiveness Analysis	Final Considerations Governing Decision
Air			
Arsenic NESHAPS	1. BAT Approach 2. Risk based	(1) $3,600/Mg (2) $85,500/Mg	Control all sources to at least BAT
Benzene NESHAPS	De-listing Benzene	(3) $158,000/Mg (4) $5/Mg (5) $350-940/Mg (6) $400/Mg (7) $990/Mg (8) $0/Mg	Decision not final
Radionuclide	Regulate - NRC/DOE facility licensees, Underground Uranium Mines, Elemental Phosphorous Plants Not Regulate - Coal Fired boilers, phosphate industry other extraction industry, and low energy accelerators	Costs were considered but no formal C/B analysis	1. Individual vs. Population Risks 2. Potential for Including Emissions 3. Available & Cost of controls 4. Effect of other Standards
Particulate NAAQS	Ranges of standards presented	Marginal benefits estimated; varies with alternative standards	Protection of health and welfare w/safety margin
Water			
Iron & Steel EG	8 Treatment levels presented	Est. Annual Cost $47.5 million Est. Annual Benefit $35.9--$727.7 million	Consent Decree/BAT
Copper Forming EG	4 Treatment levels presented	NA	" "
Benzene WQC	NA	NA	NA
Toxaphene WQC	NA	NA	NA
Endosulfan WQC	NA	NA	NA

Name and Type of Regulation/ Standard/Guideline	Regulatory Alternatives Presented	Cost-Effectiveness Analysis	Final Considerations Governing Decision
Drinking Water			
Trihalomethane MCL	Ranges of levels presented	$200,000/cancer case avoided	Feared tighter standard would lead smaller systems to stop chlorinating
Solid Waste			
Criteria for Listing (§3001)	Full spectrum of RCRA requirements	Not addressed	None
RIA for Landfills	1. Require ideal facility design 2. Spectrum of designs 3. Case-by-case guide	$/life saved	Unknown at this time
RIA for Incinerators	1. Permit Flex. 2. Performance Standard 3. Var. from 99.99% DRE on case-by-case risk analysis	Not addressed	Unknown at this time
Superfund			
Remedial Action	Determined site by site	Not finalized	Determined Site by site
Hazard Ranking System	NA	NA	NA
Pesticides			
Amitraz RPAR	1. Allow registration; 2. Use restriction 3. Conditional Registration data gathering; 4. Ban	Expressed in cases/yr. avoided; cost data on "Risks posed were minimal" for pears & apples	Need for pest control on apples not significant--was banned. Control of pests on pears was needed -- reduced exposure

Cost/Benefit
Analyses Summary
Page 3

Name and Type of Regulation/ Standard/Guideline	Regulatory Alternatives Presented	Cost-Effectiveness Analysis	Final Considerations Governing Decision
Chlorpyrifos Emergency Exemption	NA	Kansas claimed $750K loss prevention if use authorized--risks "minimal"	Risk-benefit analysis was driving force
Turbufos Registration Standard	NA	NA	Labeled prod. because of high acute toxicity Not demonstrated to cause unreasonable adverse affects
Permethrin Tolerance Action	NA	NA	No residues were detected on the raw commodity after exaggerated application rates were used.
Toxics			
PMN # 81-356	1. Section 5(e) order banning use pending further testing.	Voluntarily withdrawn	Manufacturer withdrew substances
PMN # 81-357	2. Labeling & use of respirators	"	"
PMN #82-251	"	"	"
Mesityl Oxide (test rule)	NA	Annualized costs of testing $116,510-$354,330 or $0.06-$0.19/lb.	NA
C-9 Aromatic Hydrocarbons (test rule)	NA	Annualized costs of testing $133,100-$398,500 or $.0004/lb.	NA

Cost/Benefit
Analyses Summary
Page 4

Name and Type of Regulation/ Standard/Guideline	Regulatory Alternatives Presented	Cost-Effectiveness Analysis	Final Considerations Governing Decision
PCB Electrical Transformer use Rule	1. Ban too costly 2. Equipment phase-out 3. Frequent inspections 4. containment	$237.00 per lb. not released	Court challenge of earlier regulation
MDA ($4F,decision to reg.)	Not completed	Not completed	Pre-regulatory decision allows more risk of error
NTA ($6, decision to drop)	NA	NA	NA

HAZARD ASSESSMENT SUMMARY

Name and Type of Regulation/ Standard/Guideline	Effect Endpoint	Strength of Evidence	Pre-Regulatory Risk	Post-Regulatory Risk
Air				
Arsenic NESHAPS	Lung Cancer	Animal - Inadequate (IARC) Human - Sufficient (IARC)	(1) $2.3x10^{-1}$ or 1.1--17.4 cases/yr. (2) $4.3x10^{-3}$--$6.9x10^{-2}$ or 0.1--1.6 cases/yr. (3) $6.4x10^{-4}$--$1x10^{-2}$ or 0.07--1.2 cases/yr	(1) $5.8x10^{-3}$--$9.2x10^{-2}$ or 0.21--3.4 cases/yr. (2) $9.0x10^{-4}$--$1.5x10^{-2}$ or 0.04--0.64 case/yr. (3) $9.7x10^{-5}$--$1.6x10^{-3}$ or 0.01--0.21 case/yr.
Benzene NESHAPS	Leukemia	Human - Sufficient (IARC)	(4) $5.6x10^{-4}$--$3.8x10^{-3}$ or 1 case in 6 yrs. (5) $2.9x10^{-5}$--$2.0x10^{-4}$ or 1 case in 15-90 yrs. (6) $5.3x10^{-5}$--$3.7x10^{-4}$ or 1 case in 65-450 yrs. (7) $1.4x10^{-5}$--9.5x10-5 or 1 case in 9-60 yrs. (8) $3.1x10^{-3}$--$2.2x10^{-2}$ or 1 case in 0.1-1 yrs.	(4) $1.7x10^{-4}$--$1.2x10^{-3}$ or 1 case in 3-20 yr. (5) $4.2x10^{-6}$--$2.9x10^{-5}$ or 1 case in 15-110 yrs. (6) $3.5x10^{-6}$--$2.4x10^{-5}$ or 1 case in 380-2600 yrs. (7) $1.1x10^{-5}$--7.6x10--5 or 1 case in 10-70 yrs. (8) $1.3x10^{-4}$--$9.3x10^{-4}$ or 1 cases in 2-10 yrs.
Radionuclide NESHAPS	Fatal Cancer	Radiation is a proven carcinogen	(9) $5x10^{-3}$ (10) $1-2x10^{-2}$ (11) $1x10^{-4}$	(9) $2x10^{-4}$--$4x10^{-5}$ (10) $2x10^{-3}$ (11) $3x10^{-5}$
Particulate NAAQS	Reduced lung function, increased respiratory symptoms	NA	Not available	Not available
Water				
Iron & Steel Effluent Guideline	Chronic aquatic toxicity (fish); aesthetics	Not an issue	Cyanide 59% proj. exceedance of 3.5 ug/L WQC Phenol 65% proj. exceedance of 1.0 ug/L WQC	Cyanide 16% proj. exceedance 3.5ug/L WQC Phenol 7% proj. exceedance 1.0 ug/L WQC

EXPOSURE SUMMARY

Superfund

Remedial Action	Route	Source	Population Considered	Intermedia Transfer
Eq. 1 Matthews Electroplating, Roanoke Co., VA	Ingestion of Groundwater	Release from uncontrolled waste site (chromium)	Populations exposed via drinking water from three separate wells	Ambient air and soil were considered and then discounted because of small contributions to total daily intake
Eq. 2 Lehigh Elec. & Eng. Co., Inc. Lackawanna Co., PA	Ingestion of soil; dermal contact with soil; and inhalation	Release from uncontrolled waste site (PCBs)	3 years (children); 7 years (youngsters); and adults were considered who lived within close proximity to site	Indirect exposure via surface and groundwater was also considered but was not significant
Hazard Ranking				
Eq. 1 Love Canal Niagra Falls, NY	Ingestion of drinking water from surface water; inhalation from ambient air in basements	Release from uncontrolled waste site (trichloroethene, tetrachloroethene, and Pentachlorobutadiene from air and dioxin and lindane from surface water)	Population served by surface water 77,000 people - Population within 4 mile radius by ambient air 1100 people	Groundwater was considered but was not significant
Eq. 2 Carolawn Co. Site Fort Lawn, S.C.	Ingestion of drinking water from ground water; recreation and fishing from surface water	Release from uncontrolled waste site (1,1,1-trichloroethane trichloroethene and 1,2 dichloroethene from groundwater; trichloroethane from surface water	1200 people served by groundwater 0 people served by surface water	Air and dermal routes were considered but were determined not to be significant

Exposure (Cont.d)

Superfund Hazard Ranking	Route	Source	Population Considered	Intermedia Transter
Eg. 3 Stringfellow Riverside, CA	Ingestion of drinking water from ground and surface water; inhalation of ambient air; irrigation of land from surface water	Release from uncontrolled waste site (ground water: chromium, nitrates, chlorides, sultates; surface water: DDT chronium & DDE; Air: Air: cyanides, acids, chlorides, nitrates, sulfides	Ground water - 16,724 people Surtace water - 16,724 people Air - 16,724 people within 0-4 mile radius	All media considered
Eg. 4 FMC Corp. Fridley, MN	Ingestion of drinking water from ground and surface water	Release from uncontrolled waste site (groundwater: acetone, dichloroethene mineral sprits trichloroethene; surtace water: 1,1,2-trichloroethene, trans 1,2 Dichloroethene, methylene chloride, tetrachloroethane, tetrachloroethene	Groundwater - 30,089 people Surface water - 466,415 people	Air considered but was not signiticant

HAZARD ASSESSMENT

Superfund Remedial Action	Effect Endpoint	Tox.	Persis.	Strength of Evidence	Pre-Regulatory Risk	Post-Regulatory Risk
Eg. 1 Matthews Electroplating Roanoke Co., VA	Tubular necrosis of the kidney; and hemorrhaging of the gastro-intestinal tract			Acceptable daily intake developed by NAS (1980) 100 fold safety factor over maximum NOAEL	Three wells were contaminated approximately 2 to 4 times the 50 ug/l drinking water standard	No risk - Municipal drinking water supply was extended to users of the three wells
Eg. 2 Lehigh Elec. and Eng. Co., Inc. Lackawanna Co., PA	Carcinogenicity; Teratogenicity			Not mentioned	At max. conc.of 110,000 ppm: 1×10^{-1} - 8×10^{-1} At Av. Conc. of 3700 ppm 5×10^{-3} 2×10^{-2}	At 50 ppm 4×10^{-5} - 1×10^{-4}
Hazard Ranking						
Eg. 1 Love Canal Niagara Falls, NY	Lindane Dioxin Perchloroethene	3 3 3	3 3 -	None	Surface water score = 60 Air Score = 67.56 Total Score(Sm) = 32.04	This score represented inclusion on the superfund remedial list. (National Priority List)
	3 is maximun score available according to NFPA					
Eg. 2 Carolawn Co., Site Fort Lawn, SC	Trichloroethane	3	3	None	Groundwater Score = 55.10 Surface water score = 6.04 Total Score(Sm) = 32.04	"
Eg. 3 Springtellow Riverside, CA	DDT & DDE Chromium PCBs	3 3 3	3 3 3	None	Groundwater Score = 83.67 Surface water score = 65.45 Total Score (Sm) = 61.40	"

Hazard Assessment (Cont'd.)

WASHINGTON, D.C. 20460

August 16, 1983

OFFICE OF
PESTICIDES AND TOXIC SUBSTANCES

MEMORANDUM

TO: Dick Morgenstern, Director
Office of Policy Analysis

SUBJECT: Interagency Coordination--Proposed Initiatives

This memorandum reports on the deliberations to date, as well as the initial recommendations, of the Interagency Work Group. As directed by the Deputy Administrator and your Task Force, we are proposing a portfolio of actionable initiatives--several of which could be developed into broad-scale, continuing mechanisms for interagency coordination, should they prove successful. By "portfolio", we mean that the choices to be made are not mutually exclusive, as the collection of initiatives offers some variety of subjects and mechanisms.

Thus, we have presented preliminary options--some or all of which may be selected by the Task Force for presentation to the Deputy Administrator. The proposals reflect issues of immediate concern to the Agency. The work group presents them with the understanding that the options for implementation, resource implications (both dollar and staff) description of the expected results, and time frames were not possible to develop in the time since your last meeting. We propose such work be done--probably by the lead offices for items selected for interagency activity.

Summary of Recommendations

Our portfolio of recommendations contains six initiatives for interagency coordination concerning both science and regulation. Four of the six deal with solving specific chemical assessment, regulatory process, or implementation problems. The implementation mechanisms developed for each can be considered as potential models for implementatation of other (generic or specific) problems that EPA shares with other agencies. These four initiatives are: Unified Assessment/Regulation (cadmium); Coordinated Risk Assessment; Regulatory Coordination (grain fumigants) and Coordinated Compliance.

A fifth initiative deals with another dimension of interagency relationships--expanding and enhancing EPA's connections with a single agency across all of our programs. The Centers for Disease Control (CDC) and the Occupational Safety and Health Administration (OSHA) are presented as two candidates.

The sixth initiative proposes early interagency coordination on an emerging high-technology issue of congressional and public interest. Bio-technology--the innovative combination of microorganisms as new products (with the assocated manufacture, production, use, release into the environmennt, and disposal issues)--is already confronting two of EPA's regulatory programs. Other Federal programs are already involved from a research viewpoint.

The work group views another issue--EPA's dioxin project--as a major, high priority, Agency activity with important interagency coordination aspects concerning risk assessment, regulatory coordination, and waste site clean up. We did not list it in our portfolic because the parallel activity underway on that project will contain interagency coordination plans.

Background for Recommendations

In order to develop our recommended portfolio, we conducted a census of problems or opportunities from the program offices. An abbreviated listing of these items and potentially affected EPA programs and Federal agencies appears in Attachment A. The variety in scope, degree of specificity, relative involvement of programs/agencies, elapsed time to develop solutions and/or to solve the problem is obvious from this list.

Many of these problems can be grouped under the generic functions of EPA programs:

- o unified assessments
- o regulatory coordination
- o implementation/compliance
- o communication/ information exchange

Attachment B groups most of the issues under functional headings, although some issues can easily fit in several classes.

All Federal agencies that either test or evaluate chemicals, regulate chemicals or industrial categories, or are major owners of Federal facilities are potential participants in EPA's interagency activities. Another way to view the problems and opportunities, is the frequency of other agency involvement. When the problems and opportunities are grouped under these functions, certain agencies are first tier of concern for EPA coordination. Thus, HHS(CDC), OSHA, FDA, and CPSC emerge as important players on most topics with DOD and DOE being important as owners of Federal facilities.

In addition to this census of program submissions, the work group reviewed materials describing the IRLG experience, a detailed evaluation of interagency coordination[1], recommendations of the Administrative Conference of the U.S. on these subjects, and two GAO Reports[2].

Criteria for Selection

We developed and applied five major criteria for the selection of our initiatives from the candidate list: 1) need or importance; 2) potential for success and benefit to the Agency; 3) focus on the areas of science and regulation; 4) results can be achieved within a short period of time; and 5) issues selected offer potential for a variety of mechanisms and approaches that can be used for resolution. Criteria three and four are derived explicitly from the Deputy Administrator's remarks and the ensuing discussion at your last task force meeting.

Primarily because of the regional and enforcement representation on the work group, the compliance initiative is proposed even though some work group members believe it falls outside a strict construction of criteria three. Similarly, although the bio-technology initiative seems to be a longer term (vs. criteria four) project, its unique character and the current public interest caused us to recommend it for your consideration.

Detailed Proposals

See Attachment C for Discussion of Issues and options for resolution.

I. UNIFIED ASSESSMENT

*Unified Assessment/Regulatory Coordination--Cadmium

A. Recommendation: An interagency work group should be established for the purpose of 1) developing a consensus on its health and environmental effects, estimates of cadmium's body burden (Task 1), and 2) coordinating the regualtions of cadmium across the Federal establishment (Task 2).

[2] GAO Report, Gains and Shortcomings in Resolving Regulatory Conflicts and Overlaps; June, 1981
GAO Report, Grain Fumigation: A Multifaceted Issue Needing Coordinated Attention; September, 1981.

B. Lead Office: Task 1, ORD (OHEA); Task 2, OAQPS
Program Office Involvement: ORD, OAQPS, OSWER, OW, OTS
Other Agencies: OSHA, CPSC, FDA, USDA

C. Mechanism: Work Group

II. COORDINATED RISK ASSESSMENT:

°Risk Assessment

A. Recommendation: Federal agencies should sponsor a workshop, possibly hosted by NAS, to review and update the 1979 Scientific Basis for Identifying Potential Carcinogens and Estimating Their Risks. The Administrator should meet with the heads of other agencies dealing with cancer regulation and research, encourage support for this recommended approach, and develop a collective agenda for the workshop. The workshop has several optional focal points; all aspects of quantitative or qualitative hazard assessment for carcinogens expressed in the 1979 document or only portions of these earlier guidelines (e.g. with/without consideration of exposure assessment).

B. Lead Office: ORD (OHEA)
Program Office Involvement: ORD, OSWER, OPTS, OW, OANR
Other Agencies: OSHA, CPSC, HHS, ...

C. Mechanism: Workshop

°Test Guidelines and Good Laboratory Practices

A. Recommendation: An interagency work group should be established consisting of science policy managers and science experts, to establish, on a continuing basis, a process for developing baseline guidelines for government testing and good laboratory practices. Industry and public interest groups will be involved, as needed in the process.

B. Lead Office: OPTS
Program Office Involvement: OPTS, OSWER, OW, ORD, OANR
Other Agencies: FDA, NTP, NIOSH, OSHA, NIH

C. Mechanism: Work Group

III. REGULATORY COORDINATION

°Grain Fumigants

A. Recommendation: An interagency work group should be established to consider the scope of the problem and develop an approach for the coordination of regulatory actions and coverage.

B. Lead Office: CCS
Program Office Involvement: OPP, OAQPS, OSW
Other Agencies: OSHA, DOT, FDA, USDA,

C. Mechanism: Work Group

IV. COMPLIANCE/IMPLEMENTATION:

°Interagency Referral of Compliance Information

A. Recommendation: Informal discussion should be held, initially with FDA, OSHA, and USDA to discuss the idea of developing a referral/inspection process for the purpose of identifying easily detectible violations that may indicate a firm may be in violation of major standards enforced by another agency. This effort may be planned on a pilot regional or national basis.

B. Lead Office: Region III
Program Office Involvement: Regions, Enforcement Offices for each Program
Other Agencies: FDA, OSHA, USDA

C. Mechanism: Informal discussion

V. FOCUSED INTERAGENCY ACTIVITIES:

°Centers for Disease Control

A. Recommendation: An intragency work group should be established, composed of Headquarters and Regional representatives to discuss the coordination of activities with CDC. The goal of effort is the development of a generic MOU stating Agency interests concerning EPA/CDC relationships. Specific projects will be developed by the program/regional offices and funded, as necessary, by IAG's.

B. Lead Office: OPTS/CCS
Program Office Involvement: OSWER, OPTS, OW, ORD, OANR

C. Mechanism: Work Group/MOU

°Occupational Safety and Health Administration

A. Recommendation: The Administrator/Deputy Administrator should discuss area needing interagency coordination with the Administrator of OSHA. A lead EPA as well as OSHA office should be established.

B. Lead Office: OPTS
Program Office Involvement: OSWER, ORD, OW, OANR

C. Mechanism: Informal discussion

VI. INFORMATION EXCHANGE

°Bio-Technology

A. Recommendation: An interagency work group should be established to coordinate the evaluation of potential risks from bio-technology. An IAG to establish and support the expert group should be developed.

B. Lead Office: OTS
Program Office Involvement: OPP, ORD, OSW, OW, OAQPS

Other Agencies: NIOSH, FDA, CDC, NIH

C. Mechanism: Work Group

Action Items for Task Force Consideration

In order to proceed with these short term initiatives, the following action items are recommended:

1. Feedback from the Task Force and decisions by the Deputy Administrator concerning which issues should be pursued.

2. Once the issues are selected, Lead office representatives for each inititative need to be assigned to develop briefing materials for the Administrator--complete in 3 weeks of item #1.

3. The Administrator/Deputy Administrator should meet with each of the affected agencies and discuss areas EPA proposes for interagency coordination and obtain from the other agency heads their concurrence on the need to coordinate the specific items.

4. Detailed implementation plans need to be developed by the lead offices--complete within 4 weeks of item #3.

Two other items of importance need to be highlighted. First, for several of these initiatives, EPA's own activities may not be fully coordinated. Lead office recommendations for such internal coordination for each issue should be part of the detailed implementation plans (item #4 above). Second, a number of the topics and problems on our interagency list may merit further attention by the Agency, but were not included in the recommendations. You may wish to consider further reports or other inquiries of the relevant Assistant Administrators as to the seriousness of these issues, and recommended approaches for their resolution.

I. Item: Unified Assessment and Regulatory Coordination on Cadmium

Interagency Coordination on Assessment and Regulation of Cadmium Prior to the demise of the IRLG, both interagency and intra-Agency coordination of cadmium activities were achieved through staff-level participation in IRLG meetings. The potential health effect of primary concern was kidney dysfunction (cadmium accumulates in the kidneys). EPA, required by section 122 of the Clean Air Act to announce a decision, had determined that regulation of cadmium as an air pollutant was not necessary to protect the public from cadmium-induced kidney dysfunction. This determination and the attendant health and technical analyses were discussed with IRLG participants.

Subsequently, EPA deferred the annoncement of the decision not to regulate cadmium as an air pollutant in order to update the assessment of the carcinogenic and mutagenic potential of cadmium and incorporate the findings in the decision process.

Recently, EPA's Office of Health and Environmental Assessment (OHEA) completed its updated assessment and made the draft report available for review and comment. (See the Federal Register of July 17, 1983, pages 31297 and 31298.)

II. What is the issue and why is it important?

There are two issues, one related to science, the other regulation. The first issue is whether cadmium and/or cadmium compounds are to be considered human carcinogens. Several of the offices and other Federal agencies regulate cadmium and others do not, but none treats it as a human carcinogen. It is important that all be made aware of OHEA's updated report and consider its significance to their programs. The second issue is the agencies' regulatory response (i.e. risk management) and the coordination of those activities. EPA may be setting standards for the ambient air which indicate that the OSHA standard is not stringent enough.

III. What other agencies are involved?

The following is not necessarily a complete listing. Other agencies that were involved include:

1. OSHA - Had established workplace standards for air concentrations of cadmium fume and cadmium dust.

2. FDA - Had set "action levels" for the amount of cadmium allowed in ceramic holloware and flatware. Did not, nor intend to, limit the amount of cadmium in food.

3. Dept. of Agriculture - Was considering establishing a requirement for removal of the kidneys from fowl before mechanical de-boning.

EPA requirements for cadmium had been established for drinking water, water quality, industrial effluents, waste disposal, and the use of sludge on croplands.

IV. Mechanisms for resolution.

Each agency or office must decide for itself, based on available data and on its policy, what action is appropriate. It is important, however, to exchange information so that conflicting conclusions and actions, and glaring inconsistencies might be avoided. In order to develop a coordinated regulatory approach to cadmium activities concerning the assessment of cadmium can be undertaken either in parallel with on-going regulatory development or serially.

V. Recommended Option

It is recommended that an interagency Agency work group be established for the purposes of exchanging information and reporting on activities relative to cadmium. Only small additional EPA effort would be required to establish, and participate with such a group. Two groups should be established; one lead by ORD (OHEA) to examine the health effects and a second group lead by OAOPS to coordinate interagency risk management.

Attachment C 2

I. ITEM: INTERAGENCY RISK ASSESSMENT

During the period 1975 to 1980 the Interagency Regulatory Liaison Group Work Group on Risk Assessment developed a mutually satisfactory and acceptable position on the scientific basis for the identification of potential carcinogens and estimation of risks. The IRLG report on risk assessment was published in 1979 both in the Journal of the National Cancer Institute and the Federal Register. These documents became the basis for EPA's cancer policy and was also considered for the cancer policies of OSHA, CPSC, and FDA. The IRLG document focused on risks of cancer. The document described the basis for qualitative evaluations of whether a particular substance presented a carcinogenic hazard to man. The document presented how the results of epidemiological studies, animal bioassays along with other types of information were to be used making evaluations that a particular substance was carcinogenic. The second thing the document did was to discuss and present methods for quantifying estimates of carcinogenic risk posed by a particular type substance, if such risk estimates were appropriate or required. The IRLG report represented the first time Federal agencies had taken a unified stand on risk issues and issues of uncertainty which greatly affected their regulatory activities. Since the IRLG report, much new information has become available on risk of cancer. The work has been discussed by institutions such as the National Academy of Sciences and other scientific communities, especially with regard to estimation of risk posed to the public by potential carcinogens.

II. WHAT IS THE ISSUE AND WHY IS IT IMPORTANT

With regard to interagency coordination, the major concern centering around the IRLG report is the currentness of the material which was published in 1979. Since 1981 the IRLG has failed to function as an interagency group. However, in the last three years, much new information has become available throughout the scientific community which directly affects the contents of the IRLG report.

The IRLG report is often cited as the basis for regulatory actions both in EPA as well as in other agencies. The issue posed at this time is the update of the report and how Federal agencies involved with the assessment of carcinogens and risk of potential carcinogens should go about updating the work.

III. WHAT OTHER AGENCIES ARE INVOLVED

The IRLG report of 1979 involved EPA, the Consumer Product and Safety Commission, the Food and Drug Administration, Occupational Safety and Health Administration. All these agencies involve themselves with the regulation of potential carcinogens. In addition to these agencies' interest in risk assessment, the Center for Disease Control, NIEHS, and the National Cancer Research Institute are other Federal agencies which are deeply involved in the national issues surrounding cancer and risk assessments. For the purpose of coordination, all agencies involved in risk assessment, especially those named above, should be encouraged to become involved in interagency efforts to review and revise the IRLG's scientific basis for the identification of potential carcinogens and the estimation of risk.

IV. MECHANISMS FOR RESOLUTION

Essentially there are two possible mechanisms for reviewing and revising the IRLG report of 1979. The first mechanism could be that used in the period 1975 to 1980 by resurrecting the IRLG and revisiting the work of that group using the same procedure and format. The second mechanism, could be to encourage the Federal agencies to focus on the National Academy of Sciences to hold an international forum or symposium. The topic would be "The scientific Basis for the Identification of Potential Carcinogens and Estimation of Risk." The symposium sponsored by the Federal agency could be established specifically for updating, reviewing and revising the position on carcinogenesis and estimation of risk which was presented some four years ago.

V. RECOMMENDED OPTIONS

The option recommended for the update of the report on risk assessment is for the Federal agencies to sponsor a workshop which may be conducted by the National Academy of Sciences. The lead office in EPA to coordinate the activity should be the Office of Research and Development. Specifically in that office, the Office of Health and Environmental Assessment should be given the responsibility to conduct this workshop. The mechanism recommended is for the Administrator of EPA to officially contact the heads of other agencies dealing with cancer regulation and research and encourage the above option. Main resources required are senior EPA staff to coordinate. Sums of money required for such a workshop and update are estimated to be about $200,000 for the conduct of the workshop. Low estimate for such a workshop would be $100,000 and a high estimate would be $300,000. These amounts are those which are not already committed by the Agency.

Attachment C 3

Interagency Coordination
Test Guidelines
and
Good Laboratory Practices

I. Test Guidelines and Good Laboratory Practices

This need is for interagency agreement on the acceptable, baseline methodologies for conducting toxic effects and other tests. Since the data produced by testing are the decisional base for risk assessment, agencies must begin with consistency in the data they use if they are to have consistency in risk assessment.

A successful effort was carried out at the international level, through the OECD, to arrive at consensus guidelines (protocols) for some tests. The FDA and EPA were participants.

This project would be a continuing one, since improvement in the scientific state-of-the-art requires methods to be updated frequently. However, there would also be short-term goals for the work.

II. Issues and Importance

Various regulatory and science agencies either perform testing or require it from regulated industries. It is essential not only that the agencies agree on acceptable baseline protocols for government testing, but also that they are consistent in what they require of the regulated industries.

III. Other Agencies Involved

Agencies include FDA, EPA, NTP, NIOSH, OSHA, and NIH.

IV. Mechanism

Option 1: The model would be the successful OECD effort. In that case there was a three-tiered structure. At the top were the policymakers (here it would be the Administrator and AA's and their peers). The next tier was the science polity managers (Office Director/Division Director). The last tier was science experts. Experts were drawn together as a work group for each protocol (or several related ones). Their recommendation was reported to the science policy managers who in turn reported recommendations to the policy level for adoption.

The objective is not to achieve perfect standards for testing. This would not permit the flexibility that is needed to accomodate interests of particular programs or the improvements that science can achieve over time.

Option 2: Option 1, but with requirements that make the agreed-upon baseline guidelines mandatory rather than advisory.

Option 3: Option1, and include industry and public interest group representatives on the expert groups.

V. Recommended Option

° Options 1 and 3 are recommended. Option 2 which would make guidelines mandatory would be less likely to succeed since it would require agencies to give up flexibility.

° The lead office could be OPTS or ORD. OPTS is recommended because it contains two programs that have statutory requirements for industry testing and, under TSCA, statutory requirements for producing test guidelines. Either way, both offices would have to participate fully.

° The resources required would include;

- planning and setting up an interagency group with an agreed charter.
- personnel to work in expert groups and policy level groups
- funds to support validation of some (not all) protocols

Attachment C 4

Grain Fumigants

I. Item: Coordination on Grain Fumigants

II. Issue

Fumigants to control pests in grain are of interest to several Federal agencies. Approximately 10 fumigants are used to protect grain from insect damage. EPA regulates the use of fumigants as pesticides; OSHA has authority in the workplace of those who handle or inspect grain as opposed to those who apply the pesticides; FDA monitors levels of fumigant residues in processed grain products; DOT defines the manner in which grain may be safely transported; and USDA helps shape the market trends and affects the marketability of grain. GAO did a report several years ago noting the lack of coordination between Federal agencies addressing policy issues or regulations affecting grain fumigation. In fact, there may be conflicting activities between agencies. For example, while the FDA may take legal action against processed grain products containing an excessive number of insect parts, USDA grades grain on the basis of live insects only. Policies of USDA which tend to lead farmers to store more grain also encourage increased fumigation activity. EPA is restricting the use of several grain fumigants, but still needs to pursue the interagency issue. The issue is important because of the GAO attention, and the legitimate issues of inter-agency jurisdiction and grain policy raised.

III. Other Agencies involved

OSHA, DOT, USDA, FDA

IV. Recommended Option

a. Lead office: Chemical Coordination Staff, OPTS; optional lead: Office of Pesticide Programs.

b. Mechanism: Formal interagency Work Group or Task Force should be formed to consider scope of problem and discuss course of coordinated action which can be taken by all agencies involved. Formal agreements, e.g. MOU's, could result from the efforts of the Work Group. Participation on the Work Group should be Branch Chief and/or Division Director level.

c. Resources required: Medium.

Attachment C 5

INTER-AGENCY COORDINATION COMMITTEE
IMPLEMENTATION AND COMPLIANCE PROJECT

I. ITEM: Implementation of Mechanism for the Interagency Referral of Compliance Information For Use in Targeting Use of Inspectional Resources.

A. Background.

A large number of firms subject to EPA regulation are also subject to regulation by other Federal agencies. A pharmaceutical 4irm which operates pursuant to EPA-issued water, air and waste management permits is also subject to FDA good laboratory practice standards and OSHA worker safety requirements. A meat or poultry processing house must operate in compliance with USDA standards for pesticide residues, OSHA workplace requirements, as well as EPA standards for pest management.

Each regulatory agency monitors compliance with its standards based upon its own program priorities and enforcement strategies. Each conducts periodic inspections of regulated firms as resources allow. In the absence of rigorous interagency planning, each agency would inspect a given firm to assure compliance with its standards. Flagrant violations of sister Agency's standards would go unnoticed and unreported. Furthermore, the operations of the firm would be interrupted as inspectors from each Agency appear in turn to conduct inspections.

B. Referral Inspection Process.

With a limited amount of orientation training, the field staff of each of the principle regulatory agencies could become competent to observe easily detectible (clearly visible) indications that the firm may be operating in violation of major standards enforced by a sister agency. Using a standard format, the inspector would notify a predetermined contact in the sister agency of what he has observed This information would be used by the receiving agency in determining its inspection/monitoring priorities. Where the receiving agency determines that the information warrants follow-up, it will inspect the firm and initiate appropriate corrective action.

To assure maximum value to the program, it should include the following design:

-- Identification of Referral Indicators: The standards targeted for orientation training and referral must be both (1) easily identifiable, and (2) of sufficient importance to the receiving agency that the receiving agency will want to follow-up. This will require careful selection of agency-by-agency referal indicators. As examples, the agency identified below would be interested in observations of the followings compliance problems

oo EPA: Foamy buildup around permited outfalls; leaking pesticide/waste drums; workers in the field during pesticide application; black plumes from smoke stacks; stagnant, non-maintained pits, ponds and lagoons at industrial sites; leaking PCB transformers in food processing establishments.

oo FDA: Damaged food containers, rodent droppings/insect infestations in food processing plant.

oo OSHA: Slippery floors, open vats or toxic fumes in chemcal/pesticide plants; absence of protective clothing/equipment; farm equipment without precautionary signs;

-- Training of Field Staff. The inspectors employed by each participating agency must learn to identify the key referral indicators. This training may be done by classroom or video instruction, augmented by a training manual containing all relevant training data for periodic self-instruction.

-- Transmittal of Referrals. A simple one page Inspection Checklist of referral indicators should be utilized by the field staff of the interested agencies to remind inspectors of the types of items they should try to notice. Another one page tear-off Referral Form will be used to transmit referrals to sister agencies.

--Follow-up By Receiving Agency. Each agency will determine whether a referral warrants a follow-up inspection. In some instances the receiving agency may already be aware of the problem referred, or may determine that the issue does not pose a serious problem and competing program demands will predominate.

II. Benefits To Be Achieved By Implementing An Inspection Referral Program.

Implementation of an interagency referral mechanism would effectively expand each Agency's field presence. It would provide valuable intellegence regarding instances of probable violations which the receiving agency can utilize in estbilishing compliance monitoring priorities. Since the indicators would focus on violations of concern to the receiving agency, it would minimize the referral of information of no programmatic concern.

Finally, the implementation of a formal interagency referral mechanism would enhance the credibility of each agency's compliance programs. Inspected firms would realize that an inspection by representatives of any participating agency could yield a referral to other agencies. It would have a "multiplier" effect on the overall regulatory impact of each inspection conducted by each agency.

III. Participating Agencies.

The agencies whose participation would be most useful are: EPA, FDA, OSHA, USDA.

IV. Mechanism for Implementation.

A. Formal Implementation.

A formal mechanism of interagency referral would best be implemented by the execution of appropriate MOUs or IAGs. To magnify its importance with the regulated community, the execution of the formal agreement could coincide with a campaign announcing the initiation of the program.

This campaign would need to be preceeded by discussions with large trade associations of those firms most likely to be impacted by interagency referrals to assure that the intent and process of the program is not misunderstood. Unwarranted objections to the program (regarding, for example, right of entry, cross-agency delegation of enforcement authority) must be ancitipated and directly addressed.

B. Informal Implementation.

A considerable number of interagency referrals occur already. If the execution of an MOU or IAG becomes a cumbersome process, a less formal approach could be undertaken. Interagency contacts could be made at the Office Director level among interested program managers. These individuals could establish Headquarters and Regional contact persons, agree to train their respective staffs, and agree to utilize the referral process without a formal MOU or IAG.

V. Recommended Action.

It is suggested that Region III develop implementation options for both a pilot regional or a national effort in consultation with EPA headquarters enforcement programs.

Attachment C 6

I. Item: Coordination of Activities with the Occupational Safety and Health Administration (OSHA).

The Occupational Safety and Health Administration (OSHA) within the Department of Labor is responsible for administering and enforcing the Occupational Safety and Health Act. The Directorates of Health Standards Programs and Safety Standards Programs are responsible for the development and continued review of mandatory health and safety standards concerning worker exposure to toxic chemicals and general "physical" hazards in the work place.

Under section 6 (a) of OSH Act, OSHA has designated over 400 chemical substances as air contaminants and promulgated exposure standards, threshold limit values (TLV's) for them. Under section 6 (b), OSHA has developed health standards for several chemicals to include: Asbestos, Benzene, Inorganic Arsenic, and Lead.

II. What is the issue and why is it important:

Each of EPA's program activities potentially impact and may be impacted by the activities of OSHA. A critical aspect concerns the need for interagency coordination for the evaluation of the health effects of various toxic chemicals. EPA as well as OSHA each assess chemicals to determine their acute and chronic (carcinogenic and non-carcinogenic) hazards. Each EPA Office and OSHA then as a result of these assessments make an appropriate regualtory response (based upon policy and statutory authority). Indenpendent assessment and regulatory development may result in conflicting, inconsistent and duplicative activities. Past regulatory or judical actions by OSHA (e.g Benzene) have affected the regulatory activities of EPA. There is a critical need to assure that the actions of each of the agencies are connected especially since regulations developed under authority of RCRA, TSCA, FIFRA, and CAA directly or indirectly impact worker exposure. Conversely, regulations developed by OSHA (e.g. requiring or permitting work place ventilation) can affect EPA programs.

III. What EPA Offices are Involved:

Potentially each of the EPA program offices may, at one point in time, have a need to coordinate with OSHA. The Office of Toxic Substances as a result of the new and existing chemicals programs may find the need to coordinate the regulation of a chemical through record keeping and reporting regulations or explicit control (use or exposure). The Office of Pesticides Programs regulates worker (applicator) exposures to pesticides and is concerned about worker exposure to pesticides in the non-field agricultural setting which is not subject to EPA regulation under FIFRA. The Office of Solid Waste and Emergency Response is constantally involved in worker exposure problems concerning developing regualitons for hazardous waste facilities and the clean up of hazardous waste sites. The Office of Air Quality Planning and Standards through the assessment of the need to regulate potentially toxic air pollutants becomes involved in worker exposure issues and the effects of air contaminants on health. The Office of Reasearch and Development, because of development of health and environmental assessment and risk assessment documents, is concerned about the need to have consistent assessments on chemicals of concern and an appropriate response by the agencies (e.g. cadimum).

Current activities of OSHA may also have a regulatory impact on on-going EPA activities. OSHA is currently reviewing its benzene, asbestos, and standards and working on EDB, ETO, and MDA. In addition to these specific chemicals, OSHA is also developing a chemical labeling standard, standards for labortory chemicals, a cancer policy, standards for non-ionizing radiation, and is reevaluationg its respirator standards. Below is an over-view of the potential EPA offices impacted by these efforts.

IV. Mechanisms for Issue Resolution

Due to the multitude of issues and needs concerning interagency coordination with OSHA a variety of mechanisms can be used to address each agencies neeeds. In order to simplify the approach for EPA/OSHA coordination the following three options are presented:

1. Development of a Memorandum of Understanding (MOU)--Generic

In order to address all issues both current and future, a MOU could be developed laying out the policy of each agency concerning coordination and cooperation. Specific details or issues would not be addressed in the MOU, rather areas of mutual concern (e.g. health assessment) would be addressed and, as identified, issues (e.g. benzene, cadmium) would be brought to the attention of the Agencies by contact to a lead Agency Office. Upon contact to the agency a formal/informal effort would be initiated.

Pros:

a. Presents the position of EPA and OSHA concerning what will and will not be coordinated.
b. Lays the foundation for continued interagency coordination and cooperation by allowing flexibility.
c. Assigns lead responsibility in each Agency to assure continued interagency cooperation and coordination.

Cons:

a. MOU may take a long time to initiate, while both Agencies have immediate needs for coordination.
b. Specific items needing coordination may not be identified,

or identified on an ad-hoc basis. Only program offices wanting or knowing of the interagency connection would become involved.

c. Because of the ad-hoc nature of events, difficulties would be encountered in the planning and scheduling of events.

2. Development of MOU--item specific

Another approach to interagency issue resoultion would be the development of item specific MOU Each MOU would address a specific topic and outline the responsibilities of each Agency to include resources and lead office responsiblity.

Pros:

a. Formally presents the position of each agency concerning inteagency coordination and cooperation on a specific issue.
b. Limits the scope of interagency efforts to only items listed in each MOU.
c. Allows each Agency to plan interagency activities.

Cons:

a. Limited to only items listed in MOU
b. Time consuming. A MOU would have to be developed to address each issues of concern as it develops. Unnecessary delays may occur concering problems that need immediate interagency action.

3. Open lines of Communication

As a first step to breaking down the barriers to interagency coordination would be contact by the Administrator with OSHA. A letter requesting interagency coordination and cooperation could be developed either trageting generic issues or specific issues needing interagency work. Once the lines of communication were open, EPA and OSHA offices could then on an ad-hoc basis being to work together. Lead offices could be designated to act as funnels to the appropriate offices.

Pros:

a. Relatively easy to initiate.
b. Does not requres alot of EPA resources (management/staff).
c. Because of its open ended nature, could apply to almost any issue facing EPA.

Cons:

a. Presents only a one-way approach to coordination. EPA initiating action and OSHA responding ad-hoc.
b. Agencies are not accountable to each other. Informal mechanism with no resources or committment.
c. With no formal mechanism established, potential to loose focus of effort.

V. RECOMMENDED APPROACH

In order to facilitate the coordination of activities between EPA and OSHA, the Work Group is recommending that lines of communication be opened between the two agencies. A lead office within each agency should be assigned; it will have the responsibility of assuring that appropriate interagency issues are identified and efforts are made to resolve them. Within EPA, the Office of Pesticides and Toxic Substances should have the responsiblity for coordinating Agency-wide activities for each of the program offices.

Attachment C 7

I. ITEM: Interagency Coordination with the Centers for Disease Control (CDC)

The Centers for Disease Control are responsible for the protecting of public health from disease, disability and death and are charged with enhancing the health of the American people. Within CDC, the Center for Environmental Health, the Agency for Toxic Substances and Disease Registries, and the National Institute for Occupational Safety and Health are the key organizations for targeted interagency coordination efforts.

The goal of the Center for Environmental Health (CEH) is to prevent or control environmentally related health problems occurring outside the work place. CEH conducts programs designed to assist the public health community in the surveillance, investigation, analysis, prevention and control of environmentally-induced health problems such as cancer, birth defects, injuries, environmental hazards and related chronic diseases. The Center is authorized to act on behalf of the Department of Health and Human Services for health activities to be conducted under the Comprehensive Environmental Response, Compensation and Liability Act. The Center provides technical advice and assistance through a staff of Public Health Advisors assigned to EPA regional offices, to assist EPA, State, and local officials in their efforts to address toxic chemical spills and waste dumps hazards. The Center also serves as the coordinating point in the Public Health Service for reviewing Environmental Impact Statements and for radiation emergency planning.

The Agency for Toxic Substances and Disease Registry (ATSDR), is required by law (CERCLA) to carry out the health-related aspects of CERCLA. ATSDR is required to: 1) establish and maintain a national registry of serious diseases and illness and a national registry of persons exposed to toxic substances; 2) establish and maintain an inventory of literature, research and studies on the health effects of toxic substances; 3) list areas restricted to the public because of toxic substance contamination; 4) provide medical care and testing to exposed individuals, including tissue sampling, chromosomal testing and epidemiological studies; and, 5) conduct periodic surveys and screening programs to determine relationships between exposure to toxic substances and illness.

The National Institute for Occupational Safety and Health (NIOSH) is responsible for developing recommended occupational safety and health standards. This is achieved principally through developing criteria documents (by industry and chemical), conducting epidemiological investigations, laboratory research to determine the acute and subchronic toxicity of industrial chemicals, and developing and evaluating performance criteria for environmental monitoring and engineering control technology.

II. What is the issue and why is it important:

There are several reasons for bringing together the health and environmental agencies, it is a requirement under CERCLA, the need to assure the best scientific evaluation of various chemicals, and the need to obtain a government-wide consensus on a chemical's health and environmental effects. In addition, because of recent budget cuts, EPA's Office of Research and Development has a reduced capability to respond to the epidemiologic needs of the various program offices--especially those of Superfund concerning hazrdous waste sites. Because of the expertise and capabilities of CDC, coordination and the development of specific joint porjects will materially enchance EPA's ability to respond to health/environmental concerns.

Currently, EPA and CDC coordinate on an ad hoc basis. The major impact of continuing this type of coordination will be in the areas of hazardous waste sites and identifying and evaluating potentially hazardous chemicals. Ad hoc coordination may also limit the scientific evaluation of various chemicals and prohibit the development of a procedure to systematically obtain a government-wide consensus on their health and environmental effects.

III. What EPA Programs are Involved:

Because of the nature of CDC's area of expertise, the entire Agency potentially will be impacted by EPA/CDC coordination. The Offices of Pesticides and Toxic Substances, Emergency and Remedial Response and Research and Development, as well as the EPA Regional Offices all potentially play an important role in EPA's need for coordination with the Centers for Disease Control.

IV. Mechanisms for Resolution:

Due to the variety of activities needing coordination on both the Regional and Headquarters levels, many coordinating mechanisms can be used. Such activities could include: 1) information exchange concerning research activities; 2) waste site-specific analyses; 3) peer review of health studies; 4) development of joint program evaluation techniques; 5) health data base development and data sharing; 6) development of monitoring methods, model validation and quality assurance protocols; 7) cross agency cooperation in NIOSH Criteria Document review and EPA risk assessment analysis; and, 8) development of joint broad-brush health studies.

Mechanisms could be developed that are either item specific or generic and could take the form of MOU's, IAG's, or formal or informal working groups on the Regional or Headquarters level.

Because of the complexity of issues and the large number of participants in the effort, initial efforts should be focused on scoping the problem and issues that need to be addressed.

V. Recommended Option.

In order to identify all the issues/problems and players a meeting of all program offices potentially involved should be held to review the current extent of EPA's relationship with CDC and to evaluate that relationship within the context of the Agency's overall needs for the kind of support CDC can offer. In addition, a lead office (ORD/CCS/OPRM/OPTS) should be assigned to open discussions with CDC concerning identified areas of mutual interest. Based upon agreements reached, the Agency should consider developing a formal MOU. The MOU should incorporate the basic principles that will govern cooperative activities and set forth broad areas within which cooperation will occur. The MOU would then form the basis for Agency-wide or program-specific interagency tasks to implement particular joint projects.

Lead Agency Office responsibility needs to be assigned as well as program office leads. It is recommended that the Chemical Coordination Staff be assigned the Agency lead and that, as specific items arise, program office leads be designated. Due to the complexity of the developmental work and the need for major planning and negotiations efforts, moderate to high resources would be required for CCS during the next year, with moderate resources required for the program offices. Following the first year, CCS resource needs will be reduced somewhat while program office resources will be project(s) dependent.

Attachment C 8

I. ITEM: Regulatory Coordination/Information Exchange--Biotechnology

In its broadest meaning, biotechnology is the application of biological science towards technological ends, towards the production of chemicals or life forms which have potential for commercial uses. It includes a diverse spectrum of activities, ranging from simple and clearly safe techniques such as the use of yeast to make alcoholic beverages and bread, to the complex recent technologies of gene- splicing to create modified life forms and biochemicals. For regulatory purposes, primary attention is turned to a more focussed definition--applications of genetic engineering which involve modified life forms and substances which do not occur in nature. This definition accounts for the primary risk which such substances pose, namely, that they are "exotic" and, therefore, are less likely to find natural enemies in human bodies or the environment.

II. What is the issue and why is it important?

Scientists and government regulators have serious concerns over the prospect of modified life forms being sold, distributed and used in the open environment, where they would be particularly difficult to control. Scientific uncertainties support the need for government review and evaluation prior to commercialization. For example, one unknown is whether genetically engineered organisms, released to the environment, can be infective or toxic to humans or other organisms. Another unknown is the possibility that a genetically modified organism could disrupt existing ecosystems. At this time, we have no clues as to the probability of such events with genetically engineered microbes, nor how to estimate or minimize the risk if it does exist. Of primary importance is the fact that there is uncertainty with regard to which if any areas of recombinant DNA technology will require regulatory controls.

Because EPA's role, principally through FIFRA, TSCA and ORD, will be complementing the roles of other regulatory and research programs, significant effort towards intergovernment coordination and planning will be required in order to avoid overlapping responsibilities and to ensure scientific data are available and consistent evaluations occur.

A serious technical problem, shared with other government agencies which are overseeing this area, is that there are almost no accepted methodologies for evaluating the safety of genetically engineered products. The risk assessment tools and data used for inanimate chemical substances will not apply in the case of organisms. It may take several years to have adequate testing methods and risk analysis techniques in any of these areas. At the same time, while we expect broad commericalization of these products to be a couple years in the future, we have begun to see the first of the potential biotech organisms in the TSCA premanufacture review program.

III. What other Agencies are involved:

EPA: OPTS (OTS, OPP), ORD, ODW, OWRS, OSW, OGC

Other federal agencies working on biotechnology issues include FDA, USDA, NIH, OSHA (regulations); NIOSH, NAS, OTA (assessments, legal and economic issues).

IV. Mechanisms for Resolution:

a. One option would be a broad umbrella group established for coordination of assessment, guidelines and regulatory coordination be established through a Memorandum of Understanding, special charter, or Executive Order.

An IAG to establish and support the expert group may be needed to funnel special funds for research needs such as occasional characterization of various segments of biotech. e.g., viruses, development of testing and assessment methodologies.

b. Separate MOUs or cooperative agreements could be established to separate the needed tasks, especially one for regulatory initiatives and one for scientific research, and one for risk assessment. These generally involve different agencies.

V. Recommended options:

Recommend that an umbrella expert group be established to speak with one voice for the Federal government.

EXTERNAL STAFF DRAFT
03-23-83

Proposed Process for Evaluation and Control of Toxic Air Pollutants

DRAFT

This is an EPA staff draft that is being circulated for external comment. It has not been approved by Agency management.

Strategies and Air Standards Division
Office of Air Quality Planning and Standards

PROPOSED PROCESS FOR EVALUATION AND CONTROL OF TOXIC AIR POLLUTANTS

I. INTRODUCTION

~~The purpose of this paper is to describe a process which will allow EPA to discharge more effectively its responsibilities under the Clean Air Act (CAA) for the evaluation and control of toxic air pollutants.~~

The basic goal of the Clean Air Act is to protect and enhance the quality of the Nation's air resources so as to promote the public health and welfare. Significant progress toward this goal has been made in developing scientific criteria and setting, reviewing, and implementing national ambient air quality standards. Pollutants for which ambient air standards are set* are those which may reasonably be anticipated to endanger public health or welfare and whose presence results from numerous and diverse emission sources. These often are called "criteria" pollutants because of the requirement under the CAA (section 108) to develop comprehensive criteria documents for each pollutant.

The CAA also provides for the control of non-criteria air pollutants which may adversely affect public health but for which an ambient air standard is not appropriate. These pollutants are referred to in this paper as toxic air pollutants. The principal authority under the CAA for control of toxic air pollutants is section 112, entitled National Emission Standards for Hazardous Air Pollutants. Section 112 defines "hazardous pollutant" as an "air pollutant to which no ambient air quality standard is applicable and which in the judgment of the Administrator causes, or contributes to, air pollution which may reasonably be anticipated to result in an increase in mortality or an increase in serious irreversible, or incapacitating reversible, illness." Section 111 (New Source Performance Standards) also provides for control of pollutants which adversely affect human health or welfare ~~but are not "hazardous" as defined under section 112~~.

---

*Particulate matter, sulfur oxides, nitrogen dioxide, carbon monoxide, ozone, lead

A number of substances have been identified which have a potential for adversely affecting human health and therefore are candidates for control. To date, the Agency has focused primarily on the use of section 112 to effect this control. Seven pollutants* have been listed as hazardous under section 112 and to date emission regulations have been promulgated to control four. Regulations for the remaining three hazardous air pollutants are in preparation. One additional non-criteria pollutant (sulfuric acid mist) has been regulated under section 111 for health reasons.

II. BACKGROUND

A. Extent of the Toxic Air Pollutant Problem

The general reduction in emissions of criteria pollutants as a result of State Implementation Plans and the New Source Performance Standards has significantly reduced emissions of toxic air pollutants. This results because many toxic air pollutants are emitted either as particulate matter or volatile organic compounds (precursors to ozone), both of which are controlled to meet ambient air quality standards. Regulations promulgated under the Solid Waste Disposal Act for hazardous waste incinerators also significantly reduce emissions of toxic air pollutants.

---

*Asbestos, beryllium, mercury, vinyl chloride, benzene, radionuclides, inorganic arsenic.

In evaluating the extent of the toxic air pollutant problem, the Agency must determine whether pollutants emitted by individual sources or combinations of sources pose unreasonable risks to public health. Available exposure data and health effects information and the scientific interpretation of this information do not allow a clear-cut, absolute determination of the extent of the health risks associated with toxic air pollutants for the nation as a whole. While there do not seem to be significant widespread risks, clearly there are individuals who may be exposed to potentially toxic air pollutants emitted from uncontrolled or partially controlled sources. As with other toxic chemicals, there is always the concern that exposures even at low levels may result in chronic adverse effects which may not become evident for years.

The magnitude of the toxic air pollutant problem in terms of number of pollutants and sources of emissions is difficult to determine with precision. A 1976 survey of the organic chemical industry identified over six hundred commercially important chemicals, of which about 50 were identified as potential toxic air pollutants requiring a more detailed assessment. Many source categories other than those in the organic chemical industry also may be potentially significant emitters of toxic air pollutants. These sources include mining, smelting, refining, manufacture and end-use of minerals and other inorganic chemicals; combustion; petroleum refining, distribution, and storage; solvent usage and waste disposal; mining, processing, use and disposal of radioactive substances and radioactive by-products; and various sources of non-toxic emissions which are chemically transformed into toxic air pollutants in the atmosphere.

The Agency is concerned with all human health effects, but cancer is of special concern because of the high incidence of mortality associated with it. The total number of cancer deaths is well known,* but the contribution of air pollution to this total is uncertain. Ambient air pollutants generally are thought to rank well below smoking, occupational exposure, and diet as an incremental cause of cancer.

B. Statutes Applicable to Air Toxics Control

1. The Clean Air Act

The Clean Air Act requires EPA to identify and regulate air pollutants that adversely affect public health. Three alternatives are provided for dealing with pollutants from stationary sources:

a. List the pollutant under section 108, set national ambient air quality standards under section 109, and require States to control sources through State Implementation Plans under section 110. Pollutants regulated through this mechanism are those which may reasonably be anticipated to endanger public health or welfare and which are emitted by numerous and diverse mobile or stationary sources.

b. Establish new source performance standards (NSPS) under section 111 for specific new or modified sources which "cause or contribute significantly to air pollution which may reasonably be anticipated to endanger public health and welfare." Most, but not all, NSPS are for pollutants subject to ambient air standards. In cases where an NSPS affects a pollutant not subject to an ambient air standard or not designated as a hazardous pollutant, States must regulate existing sources (of the type covered by the NSPS) as required by section 111(d).

---

*National Center for Health Statistics, Monthly Vital Statistics Reports.

c. List the pollutant as hazardous under section 112 and establish emission standards for both new and existing sources for this pollutant. Pollutants regulated under section 112 are those which "may reasonably be anticipated to result in an increase in mortality or an increase in serious irreversible, or incapacitating reversible, illness." The emission standards established by EPA are to protect the public health with an "ample margin of safety."

Section 112 has been considered in the past to be the primary statutory mechanism for controlling toxic air pollutants. However, a number of issues have complicated its implementation. For example, issues not resolved clearly to date include the establishment of toxicity to humans based on animal and/or human data, extrapolation from high-dose animal tests to low-dose human exposure at actual ambient concentrations, and identification of the appropriate level of emission controls for pollutants for which health effects thresholds have not been demonstrated adequately.

not rel

The appropriate use under section 112 of quantitative health risk estimates has been a key issue due to the uncertainty inherent in such estimates. To develop these estimates, it often is necessary to extrapolate toxic effects found at relatively high levels for animals or from exposures to humans in a workplace to very low levels typically found in ambient community exposures. On the exposure side, there is uncertainty about emission rates, dispersion patterns, short-term and long-term movement (migration) of people, and indoor versus outdoor toxic air pollutant concentration patterns. Monitoring data are limited and difficult to obtain for use in exposure assessment. All of these factors make it difficult to know the absolute magnitude of the risk to human health based on the available data.

[illegible] 5/12

Another key issue that has been encountered in implementing section 112 is whether protection should focus on individual or aggregate risk. If we can place any credence on risk estimates, results to date indicate that the total cancer incidence (number of cases per year) associated with exposure to toxic air pollutants, even on a nationwide basis, is small for a given pollutant, although individual risks for a limited number of people living close to emission sources often are estimated to be relatively high.

~~Finally, section 112 lacks an explicit economic test. Thus, a literal interpretation of section 112 would not preclude zero emissions requirements for non-threshold pollutants.~~

Principally because the Clean Air Act does not provide specific guidance on these issues, it has been difficult to establish definitive criteria for the evaluation and control of toxic air pollutants under section 112. As such, EPA has been reluctant to implement actions under this section without a clear indication that the costs of control are not unreasonably disproportionate to the health benefits when compared to other regulated pollutants. Administrative, legal, and legislative requirements, coupled with a lack of acceptable criteria for decision-making, have resulted in an evaluation process that can take from 5 to 7 years before regulations are in place. As a result of this lengthy process, while many potential pollutants are under evaluation, few have reached the final decision stage.

2. Toxic Substances Control Act

The Toxic Substances Control Act authorizes EPA to obtain information from industry on the production, use, health effects, and other matters concerning chemical substances and mixtures. If warranted after considering the costs, risks, and benefits of a substance, EPA may regulate its manufacture, processing, distribution in commerce, use, and disposal. A toxic substance as defined under this Act is any chemical substance or mixture that may present an unreasonable risk of injury to health and the environment. This definition can include pollutants in any environmental medium.

The key sections of the Toxic Substances Control Act are: section 4, testing of chemical substances and mixtures; section 5, manufacturing and processing notices (premanufacturing notification); section 6, regulation of hazardous chemical substances and mixtures; section 7, imminent hazards; and section 8, reporting and retention of information. Section 9 further states that where other Federal laws are applicable they should be used unless the Administrator determines that it is in the public interest to use this Act.

3. Solid Waste Disposal Act

The Solid Waste Disposal Act (also known as the Resource Conservation and Recovery Act) authorizes EPA to identify hazardous wastes, and to develop standards for generators, transporters, treaters, storers and disposers of hazardous waste. A hazardous waste is defined under this Act as any waste or combination of wastes that, because of its quantity, concentration, or physical, chemical, or infectious characteristics, may (a) cause or significantly contribute to an increase in mortality or an increase in serious irreversible, or incapacitating reversible, illness, or (b) pose a substantial present or potential hazard to human health or the environment when improperly treated, stored, transported, disposed of, or otherwise managed. Hazardous wastes can result in the release of pollutants to any environmental medium.

The key sections of the Solid Waste Disposal Act are: section 3001, identification and listing of hazardous wastes; section 3002, standards applicable to generators of hazardous waste; section 3003, standards applicable to transporters of hazardous waste; section 3004, standards applicable to owners and operators of hazardous waste treatment storage and disposal facilities; and section 7003, imminent hazard.

4. Comprehensive Environmental Response, Compensation and Liability Act

The Comprehensive Environmental Response, Compensation, and Liability Act of 1980 (also known as Superfund) establishes broad Federal authority to deal with releases or threats of releases of hazardous substances from vessels and facilities that may present substantial danger to public health, welfare, and the environment. The Act designates an initial hazardous substances list (section 101(14)) and allows for additions to the list by EPA's Administrator under section 102. Under section 103 of the Act, the National Response Center must be notified when a reportable quantity release occurs. Once notification is received, the government may take remedial or removal action if: (1) there is a release or substantial threat of a release of a hazardous substance or (2) whenever there is a release of other pollutants or contaminants that may present a substantial danger to public health, welfare, and the environment. Response activities are to be taken in accordance with the National Contingency Plan.

The Act provides that owners and operators of vessels or facilities who release a hazardous substance, and certain other persons who contribute to the hazardous substance incident, are liable for response costs incurred and for damages to natural resources. Failure to notify poses criminal liability. There are limitations to liability established in the Act, as well as limited defenses to the liability.

The Act incorporates, by reference, five lists of hazardous substances developed under other environmental statutes into the definition of hazardous substances. These lists are: hazardous air pollutants under section 112 of the Clean Air Act; hazardous substances under section 311 of the Clean Water Act; toxic pollutants under the Clean Water Act section 307(a); hazardous wastes under section 3001 of the Solid Waste Disposal Act (excludes those wastes omitted by statute); and imminently hazardous chemical substances or mixtures for which the EPA Administrator has taken action under section 7 of the Toxic Substances Control Act.

5. Other Statutes

Under some circumstances, toxic air pollutants also may be controlled effectively using the Federal Insecticide, Fungicide and Rodenticide Act, the Clean Water Act, or the Safe Drinking Water Act. The applicability of these statutes depends upon the physical and chemical properties of the pollutant and the medium through which the air pollutant is released to the environment.

III. OVERVIEW

This overview describes the key elements of the proposed evaluation and control process for toxic air pollutants. This process is intended to allow EPA to discharge more effectively its responsibilities on toxic air pollutants. Figure 1 shows the overall process, the flow of information, and the major decision points. The process is summarized below and described in more detail in Sections IV through VII. In order to put the evaluation and control process in perspective, times to accomplish each of the major steps are estimated in Table 1.

The proposed toxic air pollutant evaluation and control process differs principally from the past process in the following ways:

1. While the evaluation and control process continues to rely on section 112 as the primary control alternative, it clarifies the use of other sections of the Clean Air Act and other Federal and non-Federal control alternatives to provide greater flexibility in implementing a control strategy appropriate to the magnitude and type of perceived health risk.

2. The evaluation and control process formally provides, where appropriate, for the use of State and local regulatory authorities, as well as section 111, as control options, and the important role of State and local regulatory agencies in controlling air toxics is more clearly defined.

3. The public and the Science Advisory Board are involved to a greater degree to assure continued awareness of the program and to provide more opportunity for review and comment.

A. Key Elements

The proposed toxic air pollutant evaluation and control process is designed to continue use of section 112 to control air toxics which are clearly "hazardous" in the sense that exposure at ambient levels may

	Total Time Range	4 yrs.-7 yrs.

reasonably be anticipated to result in an increase in mortality and illness. However, where there is a high degree of uncertainty as to the magnitude of the relative health risks or where the use of other legislative authorities or nonregulatory control options is obvious, the evaluation and control process provides the flexibility to use these alternatives. In order to ensure that public health concerns are dealt with in the most timely and effective manner, and in order to optimize resource use, the process provides for several levels of increasingly detailed analysis. At each level of analysis a decision is made to ensure that the pollutants which receive the most detailed and resource intensive analysis are the most likely candidates for control. The public and the Science Advisory Board will be briefed periodically on the status of these efforts.

B. The Evaluation and Control Process

Over the past several years, EPA has undertaken the systematic identification, ranking, screening and assessment of a number of candidate toxic air pollutants. Additional candidate pollutants will be identified periodically and then ranked using available health and source information. The highest ranking candidates will be screened to assess their potential for relative health risks at ambient exposures. One of the following actions then will be taken: (1) Where information is not adequate to determine the appropriate next step, that information will be gathered. (2) Where public health concerns clearly are not unreasonable, the candidate will be dropped from further active consideration. (3) Where the candidate clearly poses a health concern but can more appropriately be dealt with using a statute other than the Clean Air Act, jurisdiction will be transferred to the appropriate program. (4) Where information indicates a cause for concern, the candidate will undergo comprehensive health and exposure assessment.

This comprehensive assessment is a detailed and resource intensive step that leads to formal Science Advisory Board review in public meetings and closure by the Board when it is satisfied that the document is scientifically sound and adequately represents the latest scientific knowledge. Following closure, all available information along with an analysis of feasible control options is provided to the Administrator.

Several responses are possible at this point in the process: (1) Where public health needs do not indicate that further action is required at this time, control activities will be halted and the candidate placed in a category for periodic reassessment. (2) Where State/local, voluntary or other non-Federal actions are appropriate, EPA will obtain agreements to act from the appropriate party and will provide necessary technical or support information. (3) Where Federal regulatory action is appropriate, the necessary legislative authority will be implemented.

Under the Clean Air Act, the process for developing standards begins with identification and evaluation of the appropriateness of Federal regulation of important source categories. Source categories of minimal concern will be identified as such in proposals not to regulate. Appropriate standards will be developed for source categories of concern. The basis for control will be best available technology (considering cost and other factors), with additional control possible under section 112 if the risk remaining after application of best available technology is determined to be unreasonable.

C. Resolution of Key Issues

The inability to resolve several key issues has contributed to the slow past progress in dealing with toxic air pollutants under the Clean Air

Act. While this process does not provide detailed resolution to these issues, the following summarizes generally how each will be approached:

1. How are potential human carcinogens evaluated? Given that the quality and extent of data vary greatly, EPA will evaluate the nature of the evidence in each case using a "strength or weight of evidence" approach. In the absence of sound scientific evidence to the contrary, prudent public health policy requires that where the strength of evidence is sufficient to find that a pollutant may be a human carcinogen for regulatory purposes, this substance should be assumed to pose some finite level of risk at any ambient exposure.

2. How are relative risk estimates used? To the extent possible, risk estimates (which are derived from quantitative mathematical models) will be used to compare air pollutants, sources, and alternative control options. However, it is recognized that there are uncertainties in the quantification of risks, particularly at low levels of exposure. Hence, the use of quantitative risk information as the prime factor in specific regulatory decision-making necessarily will be limited. The "strength of evidence" consideration always must take priority over the use and application of numerical estimates of risk obtained from various mathematical models.

3. What level of control is appropriate control under section 112? Best available technology (considering costs and other factors) will be required as a minimum. Additional control may be required, after consideration of the health risks, costs, benefits, and other factors, to eliminate unreasonable residual risks.

IV. ASSESSMENT OF POTENTIALLY TOXIC AIR POLLUTANTS

This section details the process by which EPA will assess potentially toxic air pollutants.

A. Identification of Candidates for Evaluation

Since initial identification, ranking and screening efforts on non-criteria air pollutants, EPA has centered its assessment work on a number of candidates. EPA will continue to develop and periodically update its list of potentially toxic air pollutants based on information from sources such as appropriate data bases, the scientific literature, monitoring studies, and biological assays of substances found in the ambient air and source emissions. Available data from other Federal agencies, State or other public testing or regulatory authorities, private research groups, and producing or consuming industries also will be considered. A preliminary ranking of pollutants will be developed based on health effects, production volume, volatility, bioaccumulation potential, and existing standards.

B. Screening

e.g. toluene screened almost solely because of high exposure

Substances of most concern will be selected periodically from the identification process. These will be screened by conducting a preliminary health and/or exposure evaluation. Based on the results, a decision will be made on the preparation of more comprehensive assessments.

The health evaluation screening consists of reviewing published data to make an initial determination of the most important potential health effects associated with the substance. The ambient exposure screening will be based on readily available information, including the number and types of sources emitting the substance in geographical areas where people may be exposed, the estimated quantity of emissions, ambient concentrations which may have been reported, and the number of people living near emitting sources or in the vicinity of ambient measurement sites.

C. Responses to Screening

This section discusses possible responses resulting from the screening process. The public and the Science Advisory Board will be advised periodically of the status of these responses.

1. Comprehensive Assessment

This step is substantially the same as that now practiced and entails expanded evaluation of exposure potential, an expanded assessment of potential sources along with possible impacts of control of these sources, and a comprehensive assessment of all important health effects. The comprehensive health assessment document is submitted to the EPA Science Advisory Board (SAB) for an evaluation as to scientific adequacy, and comments are solicited from the public for review by both EPA and the SAB.

2. Obtain Additional Information

Additional information may be needed before a judgment can be made on the screening results. The process for gathering this information could encompass a variety of approaches. EPA initially will rely on information resulting from hazardous substance data bases (such as that maintained in the Superfund program), technical studies, EPA monitoring and research requests to industrial and other sources, requests to other Federal programs (e.g., the National Toxicology Program), and requests to State and local agencies. If these do not provide the necessary information, provisions of section 114 of the Clean Air Act, applicable sections (4, 8a and 8d) of the Toxic Substances Control Act, and information gathering authorities of other environmental legislation may be used to obtain more data.

3. No Further Action

This response will be taken if available information clearly indicates that potential public health risks from exposure to ambient concentrations are not unreasonable.

V. RESPONSE TO COMPREHENSIVE ASSESSMENT

This section describes the decision-making process that follows assessment. A control options analysis first will be performed and made available to the public for review and comment. Following consideration of comments, EPA will determine the action to be taken and announce its decision in the Federal Register.

In the control options analysis, all relevant data are summarized and feasible control options identified to provide the information necessary to make informed decisions concerning the need for and extent of control. Appropriate information considered at this stage includes applicable legislative authorities, health and environmental impacts, sources of emissions, control technologies and estimated costs to improve those controls, estimated population exposure and other data. Control options for consideration include the following (note that these options are not mutually exclusive):

A. Federal Regulation

Where the potential public health impact is sufficient to warrant a national program, EPA first will consider the use of the Clean Air Act, including sections 108-110, 111 and 112. In some instances the use of another statute will be more appropriate to ensure the most timely and effective reduction in public health risk. In those cases, the control process will be consistent with the mandate of those laws, and may differ from that of the Clean Air Act process described here. Other statutes include the Toxic Substances Control Act, the Solid Waste Disposal Act, and the Comprehensive Environmental Response, Compensation and Liability Act. Criteria for selection of appropriate regulatory responses are discussed in Section VII.

B. State/local Actions

Action on the State or local level may be appropriate where the number of sources is small or geographically localized, where state regulations may be more effective than Federal regulations, and where the resulting controls are verifiable by EPA. Where State/local regulation is appropriate, EPA will obtain agreements to act from the appropriate Agency and then will provide technical and scientific support to the State and local agencies in such cases to ensure that actions are scientifically supportable.

C. Information Dissemination

In some instances, principally where the relative risks to the public health are not unreasonable but where there may be some cause for concern, dissemination of information on the possible health risks and measures for reducing those risks will be indicated. For example, where available information indicates that infrequent emissions or incidents are the dominant cause for concern, EPA will prepare information on the concerns and appropriate control measures and provide it to State and local agencies, industry and the public.

D. Other Non-regulatory Actions

In some instances, it may be much more timely and effective to seek voluntary control. Such control might be appropriate when there are a limited number of sources, all of which agree to reduce emissions to levels sufficient to protect the public health. Voluntary measures will be recommended only where health protective and verifiable by EPA. Enforceable compliance agreements will be strongly encouraged as an integral part of this option.

E. No Further EPA Action

This option is indicated when available information clearly indicates that public health needs will not be served by further action.

VI. ESTABLISHMENT OF FEDERAL REGULATIONS UNDER THE CLEAN AIR ACT

This section describes the process to be used where Federal regulation under the Clean Air Act is warranted. A brief discussion of other environmental legislation is contained in Section VII.

A. Identification of Source Categories

Preliminary to determining the sources for which Federal regulation is appropriate, a screening study is undertaken to identify the various types of emitting sources and to indicate which types may be significant enough to warrant further study toward the possible development of regulations. Among the screening factors considered are the magnitude of emissions, estimates of ambient concentrations based on model plant assumptions, the number and distribution of the sources, and the potential applicability of stationary source regulations.

B. Evaluation of Appropriateness of Federal Regulation

The significant types of emitting sources are studied in substantial detail to determine those for which the proposal of Federal regulations

Per CMA comment

is appropriate and those for which the proposal of Federal regulations is not. For the former, proposed regulations are published in the Federal Register; for the latter, proposals not to regulate are published. Public comments are solicited in both cases, and final Agency determinations (which are judicially reviewable) are published after consideration of the comments. Determinations of whether to propose regulations are based on consideration of a number of factors, including the potential for improving emission control by requiring the use of the best available technology, the practicability of producing effective and enforceable Federal regulations, the multimedia impacts of air pollution control, the number, distribution, and operational life of the sources, rough estimates of the potential for adverse health impacts, and the impact of Federal regulations on the economic condition of the industry.

C. Priorities

Whenever resources do not permit the simultaneous development of regulations for all of the sources for which Federal regulation has been determined to be appropriate, higher priorities will be given to those types of sources for which the adverse health impacts appear to be the more severe and for which the potential for improved emission control is higher.

D. Development of Emission Standards

Standards development will follow those procedures currently utilized by EPA to ensure technical currency and adequacy. These procedures include: (1) encouragement of public input at all stages of the development process, (2) comprehensive technical and economic impact analysis, (3) review by the National Air Pollution Control Techniques Advisory Committee, and (4) proposal and promulgation in accordance with the requirements of the Clean Air and the Administrative Procedures Acts. almost always inapplicable.

E. Periodic Review

EPA will review periodically the information used to support its actions and recommendations to ensure continued protection of public health.

VII. CRITERIA FOR SELECTION OF APPROPRIATE REGULATORY RESPONSE

A. Section 112 (Clean Air Act)

Under section 112 the pollutant is listed as hazardous and emission standards are established for both new and existing sources for that pollutant. Pollutants regulated under this section are those which "may reasonably be anticipated to result in an increase in mortality or an increase in serious irreversible, or incapacitating reversible, illness." The emission standards established by EPA are to protect the public health with an "ample margin of safety." ~~No specific economic tests are provided~~ in ~~section 112.~~

EPA will conduct an evaluation of the health evidence and submit an evaluation report to the Science Advisory Board for review as part of the comprehensive health assessment document. One system for classifying carcinogenicity data for which there is growing scientific support is the International Agency for Research on Cancer criteria for determining whether a compound is likely to be a human or animal carcinogen. Under this system, pollutants which are classed as having "sufficient" evidence of carcinogenicity in humans or animals would be considered as meeting the health test for regulation under section 112. An additional criterion for listing and regulation under section 112 will be evidence of significant human exposure. Other factors to be considered include the technical and administrative feasibility of implementing improved control.

what about significance/ unreasonableness of risk - for pollutant/ for source category ?

For sources that emit toxic air pollutants for which there is no evidence on which to base a threshold, emissions should be limited as a minimum to levels corresponding to the use of best available technology (BAT). This is defined as follows:

1. For new sources, best available technology is that technology which, in the judgment of the Administrator, is the best system of continuous emission reduction which (taking into consideration the cost of achieving such emission reduction, any nonair quality health and environmental impact and energy requirements) the Administrator determines has been adequately demonstrated.

2. For existing sources, best available technology also takes into account the technological and economic impacts associated with retrofits needed to apply control technology options.

Sources in a regulated source category also will be required to limit their emissions by whatever additional amount (additional to BAT) that is necessary, in the Administrator's judgment, to eliminate unreasonable residual risks to public health associated with exposures caused by these emissions.

The principal emphasis in determining any additional level of control that may be required to eliminate unreasonable residual risks remaining after the application of BAT will be on public health concern. Where available, factors considered in the judgment may include:

1. the range of relative health risks to exposed populations caused by exposures that may be encountered after controls are put in place;

2. the economic impacts, technical feasibility, and benefits of control measures beyond BAT;

3. readily identifiable benefits of the substance or the activity producing the risk; and

4. the availability of substitutes and possible health effects resulting from the increased use of substitutes.

For pollutants with serious toxic effects, but where an effects threshold can be reasonably determined, controls should be established at a level that assures that any exposed individuals are protected with an ample margin of safety.

why so protective. probably no legally required

B. Section 111 (Clean Air Act)

Under section 111, new source performance standards (NSPS) are established for specific new or modified sources which "cause or contribute significantly to air pollution which may reasonably be anticipated to endanger public health and welfare." Most, but not all, NSPS are for pollutants which are subject to ambient air standards. In cases where an NSPS affects a pollutant which is not subject to an ambient air standard, States must regulate existing sources (of the type covered by the NSPS), as required by section 111(d).

The decision to use section 111 will depend upon several factors. These include: the magnitude of population exposures; the likelihood that control beyond best available levels might be needed to protect public health; the number of sources and their locations; and, for potential carcinogens, the cancer potency and the weight of the evidence.

The NSPS established by EPA for new and modified sources will be based on criteria exactly as that described for BAT above (i.e., the best technological system of continuous emission reduction that has been adequately demonstrated considering economic, nonair quality health and environmental impact and energy requirements). States must require existing sources of the type covered by the NSPS to meet regulations reflecting BAT for existing sources. EPA will issue guidelines reflecting BAT for such existing sources. For health-based pollutants, regulations adopted by the States ordinarily must be at least as stringent as the guidelines prescribed by EPA unless economic factors, physical limitations or consideration of the remaining useful life of existing sources make application of less stringent regulations significantly more reasonable.

C. Sections 108-110 (Clean Air Act)

In some instances, a substance may be found to cause non-carcinogenic toxic effects that do not meet the "hazardous" criteria and for which emissions to the air result from numerous and diverse sources. If so, establishment of an ambient air quality standard under sections 108-110 will be considered. Promulgation of such a standard would set in motion development of State Implementation Plans for the pollutant.

D. Section 6 (Toxic Substances Control Act)

Section 6 of the Toxic Substances Control Act provides one of the most potentially useful alternatives for control of toxic air pollutants. EPA may use this section where there is reasonable basis to conclude that manufacture, processing, distribution in commerce, use, or disposal of chemical substances or mixtures presents or will represent an unreasonable risk of injury to health or the environment, and the administrative determination is made that regulation under the Clean Air Act is inappropriate or potentially ineffective. Under this Act, EPA balances the risks with the benefits of the activity and determines the most reasonable and prudent means for achieving the necessary control. This can include prohibition or limitation on manufacturing, processing or distribution in commerce, process change, requirement for special warnings or instructions, production and retention of records, prohibition of disposal methods, and requirement for notification of risk of injury. The decision to use section 6 and the method of implementation will be made only after consultation and agreement between the applicable program offices.

E. Other Environmental Legislation

In some instances, when a candidate clearly poses health concerns but the control options analysis shows that the candidate can be dealt with in a more timely and effective manner through other media programs, the appropriate environmental legislation will be utilized. The decision to utilize other legislation will be made after consultation with the program office responsible for implementing the legislative authority deemed most appropriate. If appropriate, jurisdiction will be transferred to the applicable program office.

STAPPA - 4/20

Unhappy w/ BAT - prefer LAER - don't like NSPS's - toxics should be tougher
want us to subcategorize more carefully for toxics
- use more factors - e.g. location, exposed population - than for NSPS

Goodwin: One wants BAT for even threshold pollutants - by legislation, if necessary (N.B. SIP/111(d) available)

Don't tie ourselves to "continuous" systems

Prefer 111/111(d) - because then states can consider retrofit costs case-by-case, instead of allowing these costs to degrade whole std. for existing sources

Rz - also think 111 inappropriate, because if it meets 111 criteria, it meets 112 also

Also EPA has been reluctant to share toxics information, for fear that states would then regulate

Can "bio-accumulation" be addressed in this policy?

Dr. Bernard H. [illegible]

1019 W [illegible]

EPA Planned to Alter Carter Policy on Cancer

Anne Gorsuch Burford departed official Washington months ago, but the memos she wrote as director of the Environmental Protection Agency (EPA) live on in an afterlife of their own. A particularly fascinating document turned up recently on Capitol Hill, where hundreds of EPA papers came to rest during last spring's congressional investigations. This one belongs to a series of papers entitled "EPA Emergent Issues Reports." Dated 29 April 1982, it is addressed to Craig Fuller, secretary to the Cabinet, and signed by Gorsuch.

Like others in the "emergent issues" series, it attempts to alert the White House to political troubles that may arise out of decisions made at EPA. It covers a score of topics. One of the most interesting—at least for science policy—is a short item at the end of a long section on pesticides. The note is important because it indicates unequivocally that the EPA under Gorsuch set out to relax the cancer prevention standards used by the Carter Administration. It shows that the EPA's top leader and her colleagues at the White House knew that cancer policy was being changed and that it was shifting in a direction that some would perceive as exposing the public to a greater risk.

Specifically, the memo discusses an item on page 8 headed "permethrin." This was a pesticide which had been under review for many years. Animal tests suggested that it was a carcinogen for mice but not a strong one. In the previous Administration, the EPA set strict, low-tolerance levels for residues of potential carcinogens in food, even in ambiguous cases like this. In the permethrin decision, however, the new EPA leaders changed course. They decided to allow higher residue levels, arguing that some experts had concluded that, regardless of the mouse data, permethrin did not look like a compound that would cause cancer in humans. Describing this for the White House, the Gorsuch memo says that the EPA "will soon (next month) be issuing tolerances for permethrin—an insecticide. Environmentalists will be critical because this action would not have occurred under Carter Administration Cancer policy—a policy this Administration is changing. Congressional attention likely."

Although brief, the note does indicate that the EPA's leaders went into the cancer controversy with their eyes open. They may not have been quite as unprepared for the ensuing storm as they made out in congressional testimony later on. However, they clearly were unprepared for the intensity of the storm. —Eliot Marshall

California Universities Block Animal Rights Bill

A piece of California state legislation concerning the use of animals in research was scrapped last week, giving Stanford and the University of California a surprise victory over animal rights groups. "We routed them," said JoAnne Glissen, assistant director for legislative affairs at Stanford.

The legislation, introduced by Senate Pro Tem president David Roberti (D-Hollywood) would have banned the use for research of animals that came from pounds in California and other states. Although seven states have laws that ban the use of pound animals, the California proposal, if passed, would have set a precedent in prohibiting the importation of pound animals for experimental use.

The legislation was expected to pass easily through committee and the state assembly. But at the last minute, before the committee was to take up the bill for discussion, Roberti pulled his bill, apparently because he lacked the votes to get it through.

Glissen credits the universities' success to a "new strategy." Researchers had been writing their legislators to protest the bill, but that did not seem to be working very well. As momentum for the bill picked up, the universities teamed up an unlikely pair to lobby for them—the renowned Stanford cardiovascular surgeon Norman Shumway and soap opera superstar Stuart Damon, better known as Dr. Alan Quartermaine of "General Hospital." Damon took a particular interest in biomedical research because he has a child with juvenile diabetes. The universities also recently held a press conference with two heart transplant patients who extolled the benefits of animal research.

By marching out a leading scientist, movie star, and patients, the universities put an old and effective lobbying technique to new use. Special interest groups commonly follow this pattern to push for particular biomedical research legislation. But its use to counter animal welfare legislation is novel. (Glissen knows the lobbying method well because, until recently, she was on the staff of the U.S. Senate Labor and Human Resources Committee.)

Glissen said that in addition to scientists, "we got people without white coats into the process. That made the difference." The schools may have to use the strategy again if Roberti reintroduces his legislation.

—Marjorie Sun

NSF Urged to Support Academic Supercomputing

The National Science Foundation (NSF) has been urged to spend more than $500 million over the next 3 years to improve computing on university campuses. The recommendation was made in a report delivered to the National Science Board on 18 August by a working group consisting of NSF program managers.

The report recommended in particular that ten supercomputer centers be established for use by academic researchers, and that a substantial investment be made in local facilities for individuals or groups of scientists. The current state of computing in the universities is so poor, the working group said, that "even these investments would not provide computing facilities for academic researchers comparable to those at a typical national or industrial research laboratory."

The National Science Board, which had just adopted a statement of its own urging NSF to devote more resources to engineering, including improving computational facilities on campuses, was receptive. But the Office of Management and Budget will be harder to convince that expenditures of that magnitude—more than double currently planned outlays—are needed. —Colin Norman

Fitzwater (202) 755-0344
O'Neill (202) 755-0344

FOR IMMEDIATE RELEASE WEDNESDAY, MAY 19, 1976

EPA ADOPTS INTERIM CANCER ASSESSMENT PROCEDURES

Interim cancer assessment procedures have been adopted by the U.S. Environmental Protection Agency for use in making regulatory decisions where cancer risk is a key factor.

The procedures implement a decision of October 10, 1975, that rigorous assessments of health risk and economic impact will be undertaken as part of the regulatory process.

The preamble to the procedures, signed by EPA Administrator Russell E. Train, sets forth a summary statement on EPA's approach to regulatory action for suspect carcinogens. A copy of the procedures and preamble is attached.

In approving these procedures and guidelines, Administrator Train reemphasizes the Agency's commitment to reducing the burden of suffering from cancer caused by factors in the environment and reaffirms the Agency's policy of weighing risks and benefits in its regulatory approach to carcinogens wherever possible under its enabling legislation. The procedures and guidelines will also ensure that the public has free access to the Agency's deliberations at every step of the process.

The interim cancer assessment procedures are being circulated for comment to the other Federal agencies and organizations with responsibilities in this area, including the Departments of Health, Education, and Welfare; Interior; Labor; Commerce; and Agriculture and the Council on Environmental Quality; the National Science Foundation, EPA's Science Advisory Board and the EPA Pesticide Advisory Committee.

INTERIM PROCEDURES & GUIDELINES FOR HEALTH RISK AND ECONOMIC IMPACT ASSESSMENTS OF SUSPECTED CARCINOGENS

PREAMBLE

In issuing the Interim Procedures and Guidelines for Health Risk and Econonic Impact Assessments of Suspected Carcinogens, I think it appropriate to state once again EPA's approach to regulatory action for suspect carcinogens.

Cancer is the second ranking cause of death in this country; it has a particulary severe impact on the affected individuals and their families in terms of physical and mental suffering and economic costs. There is evidence that a substantial amount of human cancer is caused by chemical and physical agents in the environment. Bioassay programs, currently testing hundreds of substances, are beginning to show that some important industrial and agricultural chemicals are carcinogenic for animals and are, therefore, candidates for regulatory action.

The EPA, by law, has responsibility to regulate many agents which may either cause or promote the development of cancer. At present, EPA is charged with the responsibility to prohibit or restrict the use of carcinogenic pesticides. EPA also has authority to regulate those carcinogens which are emitted directly to the outside air by stationary sources (such as factories) and motor vehicles, or discharged into water from point sources, or found in drinking water. Other agencies such as the Occupational Safety and Health Administration and the Food and Drug Administration also have responsibilities to regulate carcinogens. It is important to emphasize that there are serious regulatory gaps which permit undesirable exposure of the public to carcinogens. I have strongly advocated the passage of a toxic substances bill to help close those gaps.

Regulatory action against chemical carcinogens is relatively new. Until the late 1950's, no agents, either chemical or physical, had been regulated in this country on the basis of their carcinogenic action with the sole exception of ionizing radiation, which had been known to cause cancer since the turn of the century. Standards of permissible exposure to ionizing radiation were set by the arbitrary use of safety factors applied to exposure levels that were known to have produced damaging health effects. It was not assumed that these permissible exposure standards were safe but rather that they represented upper limits of exposure with the understanding that actual exposures were to be kept as low as possible. In the debate over the health effects of radioactive fallout from atomic weapons in the 1950's, the evidence for a no-threshold concept for cancer induction emerged, which supported the idea that there is no such thing as a completely safe dose; in other words any exposure, however small, will confer some risk of cancer on the exposed population.

Evidence has accumulated that indicates that the no-threshold concept can also be applicable to chemical carcinogens. On the basis of this concept, the first significant regulatory legislation relating to chemical carcinogens, the Delaney Clause of the Pure Food and Drug Act, imposed a complete ban on any food additive that showed evidence of tumorigenic activity for humans or animals. This statutory requirement represents the approach of eliminating all risk, However, it has become increasingly clear that in many areas risks cannot be eliminated completely without unacceptable social and economic consequences.

Consonant with this view, the Federal Insecticide, Fungicide, Rodenticide Act (FIFRA), which is the enabling legislation for the control of health hazards for pesticides, requires a balancing of risks and benefits as the basis for final regulatory action. We, thus, have a comparable conceptual basis for the regulation of chemicals as for ionizing radiation where the philosophy has been to eliminate or reduce exposure to the greatest extent possible consistent with the acceptability of the costs involved.

I believe that it is important to emphasize the two-step nature of the decision-making process with regard to the regulation of a potential carcinogen. Although different EPA statutory authorities have different requirements, in general two decisions must be made with regard to each potential carcinogen. The first decision is whether a particular substance constitutes a cancer risk. The second decision is what regulatory action, if any, should be taken to reduce that risk.

With respect to the first decision -- whether a particular substance constitutes a cancer risk -- in very few cases is it possible to "prove" that a substance will cause cancer in man, because in most instances the evidence is limited to animal studies. In this regard, a substance will be considered a presumptive cancer risk when it causes a statistically significant excess incidence of benign or malignant tumors in humans or animals. However, the decision that a cancer risk may exist does not mean that the EPA will automatically take regulatory action. In the case of pesticides, the decision that a presumptive cancer risk exists will trigger the detailed and independent risk and economic assessments that form the basis for the second decision, namely, what, if any, regulatory action to take to eliminate or restrict the use of the pesticide. In other regulatory areas, for example those under the Clean Air Act, the Federal Water Pollution Control Act, or the Safe Drinking Water Act where a large number of suspect carcinogens may exist in the atmosphere or public water supplies, the detailed risk benefit assessment will, because of limited Agency resources, necessarily have to be carried out on a priority basis in terms of which agents appear to be the most important.

Once the detailed risk and benefit analyses are available, I must consider the extent of the risk, the benefits conferred by the substance, the availability of substitutes and the costs of control of the substance. On the basis of careful review, I may determine that the risks are so small or the benefits so great that no action or only limited action is warranted. Conversely, I may decide that the risks of some or all uses exceed the benefits and that stronger action is essential.

In considering the risks, it will be necessary to view the evidence for carcinogenicity in terms of a warning signal, the strength of which is a function of many factors including those relating to the quality and scope of the data, the character of the toxicological response, and the possible impact on public health. It is understood that qualifications relating to the strength of the evidence for carcinogenicity may be relevant to this consideration because of the uncertainties in our knowledge of the qualitative and quantitative similarities of human and animal responses. In all events, it is essential in making decisions about suspect carcinogens that all relevant information be taken into consideration.

In my opinion, the current guidelines represent a significant improvement in the Agency's approach to the processes of decision-making for carcinogens by providing improved procedures for making risk and benefit assessments while providing the maximum opportunity for public review of the Agency's deliberations. However, while these guidelines should improve Agency procedures, I do not view them as representing a change in the Agency's cancer policy. Earlier regulatory decisions involving various pesticides were also based in each case on a comprehensive evaluation of the scientifc evidence and a careful weighing of risks and benefits. These decisions in every instance resulted in selective control measures rather than a complete prohibition of use.

I want to emphasize that I will not permit these new procedural guidelines to unduly delay regulatory decision-making. I will be closely reviewing them to assure that they do not do so. If they do cause undue delay, they will be revised. I would like to point out that these guidelines provide a means of organizing available information rather than requirements for the acquisition of new information.

I believe that the approach presented here is a significant step toward the objective of achieving real benefits in improved public health while avoiding the burden of undesirable regulatory action. I recognize that the aspect of cancer research dealing specifically with the issues involved in decision-making is relatively undeveloped, but hopefully the commitment of this Agency and other Federal agencies to the development of new knowledge in this area will improve the scientific basis for regulatory decisions and that the Interim Procedures and Guidelines will thereby benefit from periodic revision.

I consider it extremely important that the leading government agencies work closely with each other and with experts outside the government in the field of carcinogenicity in the development of government procedures and policies concerning cancer. I am publishing these interim procedures and the guidelines in the Federal Register not only to provide public notice of the approach which EPA will be following in our current activities but also to stimulate commentary from all sources upon that approach. I am also furnishing copies of these Interim Procedures and Guidelines to and requesting the views of the Secretaries of Health, Education, and Welfare, Interior, Labor, Commerce and Agriculture and also the Council on Environmental Quality, the National Academy of Sciences, the National Science Foundation, EPA's Pesticide Policy Advisory Committee and EPA's Science Advisory Board, among others. I also plan to meet personally with leading authorities in this area as part of a continuing process to discuss these cancer policies and exchange information and views.

Administrator

Interim Administrative Procedures for Regulatory Decisions Involving Suspected Carcinogens

Procedures described in this paper provide a more uniform Agency approach to regulatory decisions involving cancer risk. Procedure A applies to pesticide decisions involving the cancellation, suspension and registration of potentially carcinogenic pesticides. Procedure B applies to other selected Agency decisions where the pivotal factor in the decision is cancer risk.

The purpose of these procedures is to assure that appropriate analyses of the risks and benefits of suspected carcinogenic chemicals are performed as part of the regulatory process. Appendices I and II establish guidelines for risk assessment and economic impact analyses. These guidelines are procedural guidelines and are not intended to affect the substantive regulatory standards of any statute. Therefore, the assessment of the risk posed by potentially carcinogenic substances will be made pursuant to the individual standards of the applicable statute and regulations. Furthermore these analyses will be carried out within the constraints of Agency resources and will not delay actions by the Agency to address urgent environmental problems.

The Cancer Assessment Group (CAG) is an advisory body comprised of senior scientists from within the Agency with a liaison member from the Department of Health, Education and Welfare. It will also utilize, as appropriate, expert consultants and advisors from various Federal Agencies and the private sector. The CAG will conduct analyses of data related to risk and make recommendations to the lead program office and the appropriate Working Group concerning the risk associated with each suspect carcinogen. These analyses will be directed towards risk assessment and will be conducted independently of economic impact analyses. The CAG will also review the final risk assessment portion of the regulatory package.

Applicability

For all decisions involving the cancellation, suspension, reregistration and registration of potentially carcinogenic pesticides, Procedure A will be followed inclusive of the preparation of (1) a risk assessment pursuant to the interim guidelines contained in Appendix I and (2) an economic impact analysis pursuant to the interim guideline contained in Appendix II.

For the following rulemaking, where the pivotal factor in the decision is cancer risk, the procedures outlined in EPA Order 1000.6 will be followed, and in addition, a risk assessment pursuant to Appendix I will be prepared and will be reviewed in accordance with Procedure B:

1. Proposed regulations to augment the current list of toxic substances published pursuant to Section 307(a) of the FWPCA and any standard proposed under this augmented list.
2. Primary drinking water regulations or revisions thereof under Section 1412 of SDWA.
3. Additions to or revisions of the water quality criteria (pursuant to Section 304(a) of FWPCA) currently pending publication, except that detailed exposure patterns and estimates of cancer risk need not be prepared.

4. Proposed technology-based regulations or revisions pursuant to Sections 301, 304, 306, 307(b) and 307(c) of the FWPCA (proposed after April 1, 1977), and Section 111 of the CAA, except that detailed exposure patterns and estimates of cancer risk need not be prepared.

For all other rulemaking under existing legislation which involves the regulation of a potential carcinogen(s), and which is not currently under development, the determination of whether and to what extent to use Appendix I and Procedure B will be made at the time the Administrator approves the plan for such rulemaking.

Where the development of a surrogate parameter is being proposed to regulate one or more potential carcinogens and perhaps other pollutants (e.g., a total organic carbon standard for drinking water), the risk assessment, as required above, will address at least one of the potential carcinogens and should address, to the extent feasible, as many of the others as possible.

All risk assessments need only be based on currently available information. These procedures do not require the undertaking of research or monitoring to expand the available data base.

A. Procedure for Pesticide Decisions Involving Potential Carcinogens

This procedure is similar to the current procedure for informal rulemaking set forth by EPA Order 1000.6.

1. Formation of the Working Group

The Deputy Assistant Administrator for Pesticides, in cooperation with the Office of Planning and Management, establishes a working group.

2. OPP/Working Group Responsibility

The Office of Pesticide Programs (OPP), in consultation with the Working Group, is responsible for developing a Data Summary Report, a Position Document (including health risk assessment and the economic impact analysis) and a proposed Federal Register Notice at the appropriate points in the regulatory process. Guidelines for health risk assessment and economic analysis are included as Appendices I and II.

3. Review of a Suspect Chemical Prior to Reregistration or the Issuance of a Rebuttable Presumption Against Registration (RPAR)

a. Data relevant to the carcinogenicity of a pesticide is submitted to the CAG for review and comment. Following review by the CAG, a Data Summary Report is prepared by OPP and the Working Group. This report includes a summary of all available data relevant to carcinogenicity.

b. A draft Position Document including the Data Summary Report, a summary of the issues surrounding potential regulatory actions, and a proposed Federal Register Notice are presented to the Pesticide Chemical Review Committee (PCRC) which includes a representative from the CAG.

c. On the basis of PCRC comments, the OPP and the Working Group revise the draft Position Document and the Federal Register Notice. The PCRC reviews the revised package.

d. The package recommending a reregistration or the issuance of a RPAR goes to the Deputy Assistant Administrator for Pesticide Programs for a final decision.

4. Post-RPAR: Issuance of a Notice of Intent to Cancel, Suspend or Reregister

a. After a RPAR is issued, and rebuttal information if any is submitted, the OPP and the Working Group develop a final Position Document. This document includes a summary of all information available in rebuttal of the RPAR, a recommended finding on whether or not the presumption against registration has been rebutted (including the risk assessment), economic impact analysis as necessary, a summary of the issues surrounding potential regulatory actions, and a draft Federal Register Notice.

b. The final Position Document is reviewed by PCRC and the risk assessment is reviewed by CAG.

c. If the decision is to reregister the product, a notice to this effect is published in the Federal Register.

d. If the decision is to cancel or suspend the product, the proposed notice of intent to cancel or suspend is forwarded to USDA and the Scientific Advisory Panel for comment, pursuant to the 1975 amendments to Section 6(b) of FIFRA. However, if it is determined that suspension of the pesticide is necessary to prevent an imminent hazard to humans, the 1975 amendments provide for waiver of the requirement for consultation with USDA and the Scientific Advisory Panel.

The notice of intent to register, cancel or suspend, including the risk assessment and economic impact analyses, is circulated for General Counsel and Assistant Administrator concurrence and forwarded to the Administrator for a final decision.

B. Other Rulemaking to Regulate Carcinogens

All other Agency decisions involving carcinogenesis as the pivotal factor will follow EPA Order 1000.6 with the following additions:

1. The CAG will review the relevant data during the development of the rulemaking and make recommendations to the lead office and the working group regarding the interpretation of the data and provide other advice, as appropriate, concerning the risk assessment.
2. The CAG will review that portion of the rulemaking package containing the risk assessment. CAG comments will be presented to the Steering Committee.

C. External Scientific Review

In addition to the external reviews required by statute and the 1000.6 process, other external scientific review will be obtained in appropriate cases as determined by the lead program office. This review may take place at any time in the development of the regulatory package.

While risk and economic impact analyses may be reviewed externally, regulatory recommendations will not normally be submitted for external review. Reviewers for risk analyses may be from the Science Advisory Board, National Cancer Institute, or other appropriate Institutions.

APPENDIX I

Interim Guideline
for
Carcinogen Risk Assessment

1.0 Introduction

This preliminary guideline describes the general framework to be followed in developing an analysis of carcinogen risks and some salient principles to be used in evaluating the quality of data and formulating judgements concerning the nature and magnitude of the cancer hazard from suspect carcinogens.

This guideline is to be used within the policy framework already provided by applicable statutes and does not alter such policies. The guideline provides a general format for analyzing and organizing available data. It does not imply that one kind of data or another is prerequisite for regulatory action to control, prohibit, or allow the use of a carcinogen. Also, the guideline does not change any statutory-prescribed standards as to which party has the responsibility of demonstrating the safety, or alternatively the risk, of an agent.

The analysis of health risks will be carried out independently from considerations of the socio-economic consequences of regulatory action.

The risk assessment document will contain or identify by reference the background material essential to substantiate the evaluations contained therein.

2.0 General Principles Concerning the Assessment of Carcinogenesis Data

The central purpose of the health risk assessment 1/ is to provide a judgement concerning the weight of evidence that an agent is a potential human carcinogen and, if so, how great an impact it is likely to have on public health.

Judgements about the weight of evidence involve considerations of the quality and adequacy of the data and the kinds of responses induced by the suspect carcinogen. The best evidence that an agent is a human carcinogen comes from epidemiological studies in conjunction with confirmatory animal tests. Substantial evidence is provided by animal tests that demonstrate the induction of malignant tumors in one or more species including benign tumors that are generally recognized as early stages of malignancies. Suggestive evidence includes the induction of only those nonlife shortening benign tumors which are generally accepted as not progressing to malignancy, and indirect tests of tumorigenic activity, such as mutagenicity, in-vitro cell transformation, and initation-promotion skin tests in mice. Ancillary reasons that bear on judgements about carcinogenic potential, e.g., evidence from systematic studies that relate chemical structure to carcinogenicity should be included in the assessment.

When an agent is judged to be a potential human carcinogen, estimates should be made of its possible impact on public health at current and anticipated levels of exposure. The available techniques

---

1/ This health risk assessment is part of the risk-benefit analyses. In actions taken to regulate pesticides, this assessment is made after a determination that a health risk exists.

for assessing the magnitude of cancer risk to human populations on the basis of animal data only are very crude due to uncertainties in the extrapolation of dose-response data to very low dose levels and also because of differences in levels of susceptibility of animals and humans. Hence, the risk estimates should be regarded only as rough indications of effect. Where appropriate, a range of estimates should be given on the basis of several modes of extrapolation.

Expert scientific judgements in the areas of toxicology, pathology, biometry, and epidemiology are required to resolve uncertainties about the quality, adequacy, and interpretation of experimental and epidemiology data to be used for the risk assessment.

3.0 Format of the Risk Analysis

3.1 Exposure Patterns

This section should summarize the known and possible modes of exposure attendant to the various uses of the agent. It should include or identify by reference available data on factors relevant to effective dosage, physical and chemical parameters, e.g., solubility, particle size for aerosols, skin penetration, absorption rates, etc. Interaction of agents which may produce a synergistic or antagonistic effect should also be indicated, if available.

3.2 Metabolic Characteristics

This section should summarize known metabolic characteristics including transport, fate and excretion, and biochemical similarities to other known classes of carcinogens at high and low dose levels and should provide comparisons between relevant species as well as variations in different strains of certain species.

3.3 Experimental Carcinogenesis Studies

Available experimental reports should be summarized. If some experiments are to be rejected for the risk assessment, give reasons for doing so. Reprints of key papers and reports should be included as appendices to the analysis.

Judgements should be provided on the quality of the experimental data and their interpretations for each study on the basis of (a) experimental protocols, (b) survival rates in controls particularly in relation to acceptance of negative results, (c) incidence of spontaneous tumors in the control compared to general laboratory experience for the same species or strain, (d) diagnostic criteria and nomenclature used for tumor characterization (additional evaluation of histological material should be obtained when appropriate), and (e) observed results of positive controls (i.e., a test group given a standardized exposure to a known carcinogen) in light of expected results.

3.4 Epidemiological Studies

Summarize epidemiological studies, together with critiques of the work with respect to its limitations and significance. Summarize other published critiques whether supportive or at variance with the judgement made here.

3.5 Cancer Risk Estimates

3.5.1 Exposure Patterns

Describe likely exposure levels with respect to long-term temporal trends, short-term temporal patterns, and weighted averages for both the total exposed populations and for subgroups whose exposure patterns may be distinctly different from the average. Characterize, to the extent possible, the size of the exposed population for each of the above categories with an indication of whether the exposures are likely to involve children and pregnant women. Discuss the adequacy of the methods used to estimate exposures and indicate the range of uncertainty in the estimates.

3.5.2 Dose-Response Relationships

Both human and animal data should be used as available. Include available human data, even if inadequate for a characterization of the actual magnitude of risk, where such data could be helpful in interpreting animal responses in relation to human sensitivity.

3.5.3 Estimates of Cancer Risk

The procedure will involve a variety of risk extrapolation models, e.g., the linear non-threshold model and the log-probit model. Analyses will be done separately for all suitable experimental data and human epidemiological data. The results should be presented in terms of excess lifetime incidence, or average excess cancer rates; life-shortening estimates should also be made when the data permit. The uncertainty in the data and extrapolation techniques should be clearly indicated. The results predicted for humans should be presented in relationship to the current cancer experience in the assumed target organ(s).

Some judgements should be included regarding the relevance of the mode of exposure used in animal studies to that associated with human exposure.

4.0 Summary

The summary section of the risk assessment should provide a statement which encompasses answers to the following questions: (1) How likely is the agent to be a human carcinogen? (2) If the agent is a human carcinogen, what is the estimated impact on human health?

APPENDIX II

INTERIM GUIDELINE FOR ECONOMIC IMPACT ANALYSIS OF PROPOSED REGULATORY ACTIONS TO CONTROL CARCINOGENIC PESTICIDES

The purpose of this guideline is to define the factors to be considered and the procedures to be utilized in assessing the economic impact resulting from future regulatory actions (as described below) affecting carcinogenic pesticides. Economic impact assessment for other regulatory actions to control environmental carcinogens will follow established agency procedures.

The principal concern in the economic analysis will be the assessment of economic impacts on pesticides users and on the consumers of the products of the users. The impacts on pesticide manufacturers are not germane to this type of regulatory decision, in which the risk of the use of a pesticide is compared to the benefit of those uses.

As used in this guideline the economic impact of the regulation is equated to the anticipated loss in benefit from use of the pesticide. For agricultural pesticides the analysis will focus on the impacts on farmers, farm productivity, and consumer costs associated with farm productivity. Similarly, analyses of other pesticides will focus on the impacts on other user groups and related effects on the economy.

Regulatory Procedures

The purpose of this section of the guidelines is to define how the economic impact analysis fits into the regulatory framework for pesticide-related actions.

If a pesticide meets or exceeds criteria defined in 40 CFR §162.11, a Rebuttable Presumption Against Registration (RPAR) will be issued. The Agency will analyze any rebuttal information that is submitted; it may also take into account other available information to determine whether the RPAR has been rebutted. At the conclusion of this risk assessment, the Administrator will be presented with sufficient evidence to determine if the use of a pesticide poses the risk of a significant adverse effect. If such is the case, then the Administrator must determine what type of regulatory response is warranted.

In making that decision, 40 CFR §162.11 provides that the Administrator will be provided with a preliminary assessment of the benefits of the use of the pesticide. Furthermore, §162.11 essentially provides: (1) that if the risks appear to outweigh the benefits, the Administrator will issue a notice of intent to cancel, which may lead to a full adjudicatory hearing on the question of whether the pesticide causes or will cause unreasonable adverse effects on the environment, or (2) if the benefits appear to outweigh the risks, the Administrator will either issue a notice of intent to hold a hearing (adjudicatory or non-adjudicatory) or a notice of intent to register. Such a notice of intent to register provides an opportunity for a hearing upon request (accompanied by submission of a statement of factual reasons) of an interested party that a hearing is warranted. The decision to cancel reached at this time will not result in the removal of a product from the market if the decision is contested. Instead, any such regulatory action will be preceded by a hearing to weigh fully the risks and benefits of the uses of a product.

The benefit evidence provided to the Administrator at this stage is by definition a preliminary staff analysis. A specific effort will be made by the Agency to contact parties that have an interest in the use of the pesticide and to attempt to solicit their comments on the benefits of the pesticide under review. In particular, EPA intends that the U.S. Department of Agriculture will be heavily relied upon from the earliest stages of review to provide its special expertise and data resources on uses.

Because of the many variables surrounding the multiple uses of different pesticides, the benefit or economic impact analysis must of necessity be done on a case-by-case basis. All relevant economic considerations raised in criticisms of the preliminary benefit analysis will be addressed prior to final action.

Content of the Economic Impact Analyses

Based upon all the available information, a preliminary analysis will be developed. Such analysis will be organized in the following manner:

1. Identification of the major uses of the pesticide, including estimated quantities used by crop or other application.
2. Preliminary identification of the minor uses of the pesticide, including estimated quantities used by category such as lawn and garden uses and household uses.
3. Identification of registered alternative products for the uses set forth in (1) and (2) above, including an estimate of their availability.
4. Determination of the change in costs to the user of providing equivalent pesticide treatment with any available substitute products.
5. Assessment of regulation impact upon user productivity (e.g., yield per acre and/or total output) from using available substitute pesticides or from using no other pesticide.
6. If the impacts upon either user costs or productivity are significant, a qualitative assessment of the regulation's impact on production of major agricultural commodities and retail food prices of such commodities.

Environmental Protection Agency, Rm. E-124, 401 M St., SW., Washington, D.C. 20460, (202-426-223).

SUPPLEMENTARY INFORMATION: Flax does not compete well with weeds; weed infestations result in poor stands of flax by reducing germination and competing with the developing flax plants. Wild oats and foxtails are common weed pests of flax. According to the Applicants, these weeds are present in all areas where flax is produced, and due to heavy snowfall this past winter, heavy weed growth delayed planting and shortened the time for use of preplant herbicides.

Eptam, Avadex, Dalapon, Carbyne, MCP Amine and Bromoxynil are registered for selective weed control in flax. According to the Applicants, the registered alternative pesticides are either not effective or are not acceptable control methods for wild oats, wild buckwheat and foxtails for this season's wet conditions.

Minnesota reports that Kittson, Lake of the Woods, Marshall, Pennington, and Roseau Counties, where flax is a major crop, grow from 75,000 to 95,000 acres of flax annually. Significant losses in agricultural income may be incurred, the Applicants claimed, if the exemptions were not granted.

North Dakota reports that Bottineau, Cavalier, Pierce, Pembina, Rollette, and Towner Counties annually grow about 98,000 acres of flax.

The Applicants proposed to use an asulam formulation, Asulox, EPA Reg. No. 359-682, in a single post-emergence application when wild oats are in the three- to four-leaf stage. Applications will be made by both private and commercial State-certified applicators using both ground and air equipment in Minnesota and ground equipment only in North Dakota in the counties named above.

EPA has determined that the available data are adequate to support the proposed use of Asulox on flax. Residues of the active ingredient (a.i.) asulam are not likely to exceed 2.0 parts per million (ppm) in flax seed and its fractions or 2.5 ppm in flax straw. EPA has deemed these levels to be adequate to protect the public health. Appropriate crop rotation restrictions have been imposed. No unreasonable adverse effect on the environment from this use of asulam is anticipated.

After reviewing the application and other available information, EPA has determined that the criteria for exemptions have been met. Accordingly, the Applicants have been granted specific exemptions to use the pesticide noted above until October 31, 1980, to the extent and in the manner set forth in the applications. The specific exemptions are also subject to the following conditions:

1. A single post-emergence application of Asulox (EPA Reg. No. 359-682) is authorized.
2. Application shall be made by air and/or ground equipment in Minnesota and by ground equipment in North Dakota, at a rate not to exceed 1.25 pounds a.i. per acre.
3. A maximum of 10,000 gallons of formulation may be applied to 32,000 acres of flax in the five Minnesota counties mentioned above; a maximum of 68,000 acres of flax in the six North Dakota counties named above may be treated.
4. Applications will be made when wild oats are in the 3-4 leaf stage.
5. All applications shall be made by State-certified private and commercial applicators.
6. Precautions shall be taken to avoid or minimize spray drift from target area. Application may not be made when weather conditions favor spray drift.
7. Residue levels of asulam are not expected to exceed 2.0 ppm in flaxseed and its fractions (meal, oilseed cake, refined oil, and soapstock) and 2.5 ppm in the flax straw. The Food and Drug Administration, U.S. Department of Health and Human Services, has been advised of these actions. Any resulting residues in meat, milk, poultry, and eggs will be well below detectable levels (0.05 ppm in meat, 0.025 ppm in milk, and 0.1 ppm in poultry tissues and eggs).
8. Crops other than small grains may not be planted in the treated area within 12 months of application. Small grain crops may not be planted within ten months of application. Root crops may not be planted in the treated area within 18 months of application. Fodder from grain crops rotated to treated flax fields may not be grazed or cut for forage.
9. All applicable directions, restrictions, and precautions on the EPA-registered label must be followed.
10. Application of Asulox to flax may result in crop injury and reduction in yield under stress conditions or if the herbicide is applied at stages of growth other than those specified.
11. The EPA shall be immediately informed of any adverse effects resulting from the use of Asulox in connection with these exemptions.
12. Each Applicant is responsible for ensuring that all of the provisions of its specific exemption are met and each must submit a report summarizing the results of this program by January 15, 1981.

(Sec. 18 as amended 92 Stat. 819; (7 U.S.C. 136p))

Dated: November 6, 1980.

James M. Conlon,

Associate Deputy Assistant Administrator for Pesticide Programs.

[FR Doc. 80-35270 Filed 11-12-80; 8:45 am]

BILLING CODE 6560-32-M

[HP FRL 1563-2]

Mutagenicity Risk Assessments; Proposed Guidelines

October 30, 1980.

AGENCY: Environmental Protection Agency.

ACTION: Proposed guidelines for Mutagenicity Risk Assessments.

SUMMARY: The Environmental Protection Agency has developed Guidelines for Mutagenicity Risk Assessments (Guidelines). These Guidelines will be used within the policy and procedural framework provided by the various statutes which EPA administers, to guide Agency analysis of mutagenicity data.

These guidelines were developed by an Agency-wide working group, under the direction of the Reproductive Effects Assessment Group (REAG). REAG is an advisory body located within the Agency's Office of Research and Development, which serves as the senior Agency technical review group for mutagenicity assessment performed by Agency program offices. A preliminary draft of the Guidelines was sent for review to approximately 30 scientists in the field of chemical mutagenesis within government, universities in the United States and abroad, and the private sector. In general, the comments received were favorable, and changes in the draft were made, as appropriate, in response to them. In addition to soliciting public comments on the Guidelines by publication of this **Federal Register** Notice, the Agency is providing them to the Agency's Science Advisory Board for review.

FOR FURTHER INFORMATION CONTACT: Dr. Donna Kuroda, 202/426-2275.

DATES: Comments must be submitted by February 11, 1980.

ADDRESS: Reproductive Effects Assessment Group (RD-689), Office of Health and Environmental Assessment, Environmental Protection Agency, 401 M Street SW., Washington, D.C. 20460.

SUPPLEMENTAL INFORMATION:

I. Introduction

As a result of the progress in the control of infectious diseases, increase in average human lifespans, and better procedures for identifying genetic disorders, a considerable heritable genetic disease burden has been recognized in the human population. It is estimated that at least 10% of all human disease is genetically related, resulting from changes in the composition or arrangement of genes and chromosomes (1, 2). Such genetic diseases can lead to structural or functional health impairments. Moreover, many of these diseases are expressed in infancy and in early childhood and are chronic in nature. As a result, they cause a severe impact upon the affected individuals and their families in terms of physical and mental suffering and economic losses, and upon society in general, which may often become responsible for institutional care. Some examples of genetic diseases and syndromes genetically based include Down's syndrome and Klinefelter's syndrome, cystic fibrosis, hemophilia, sickle cell anemia, and achondroplastic dwarfism. Other commonly recognized diseases which are likely to have a genetic basis include hypercholesterolemia, rheumatic fever, hypertension, pyloric stenosis, glaucoma, allergies, and several types of mental retardation. These diseases are only a few of the thousands which are associated with genetic errors (3).

Mutations are largely recognized as being deleterious to the organisms receiving them. The adverse effects may be manifested at the biochemical, cellular, and physiological levels of organization. Although mutations are the building blocks for further evolutionary change of species, it is believed that increases in the mutation rate above the spontaneous level will lead to an accumulation of deleterious mutations in the human population (4). Since the existing incidence of human genetic disease is already sizable, the Agency wants to control exposures to chemicals which may add to this existing burden.

Because of the technical and industrial expansion during the last two decades, a large number of chemicals have been released into our environment. Some have been shown to have mutagenic activity in mammalian and submammalian test systems, and thus have the potential to increase genetic damage in the human population. Chemicals with mutagenic activity in various test systems have been found widely distributed among drugs, food additives, cosmetics, industrial compounds, pesticides, and consumer products. As our knowledge of genetics and disease etiology increases, it is reasonable to believe that we will become aware of some chemically-induced human genetic effects. The extent to which exposure to these natural and man-made environmental agents may have increased the amount of genetic damage in the present human population and contributed to the mutational "load" that will be transmitted to future generations is unknown at this time. Since the prospect of curing most heritable diseases caused by mutagens in the near future is unlikely, minimizing exposure to mutagens is among the best available means to protect against further deterioration of the human gene pool.

This document describes the procedures that the Environmental Protection Agency (EPA) will follow to evaluate the risk associated with the exposure of humans to chemical mutagens. Previously, the Agency indicated its intent to develop procedures in the "Criteria for Evaluating the mutagenicity of chemicals" which describe the basic concerns and need for such a document (5). These procedures will ensure quality and consistency in the Agency's scientific risk assessments for mutagenic effects. The necessity for a consistent approach to evaluate the mutagenic risk from chemical substances arises from the authority conferred upon the Agency by a number of statutes to regulate potential mutagens. These statutes include the Federal Insecticide, Fungicide, and Rodenticide Act, the Toxic Substances Control Act, the Clean Air Act, the Federal Water Pollution Control Act, the Safe Drinking Water Act, and the Resource Conservation and Recovery Act.

The mutagenicity risk assessments prepared pursuant to these guidelines will be utilized within the requirements and constraints of the applicable statutes to arrive at regulatory decisions concerning mutagenicity. The standards of the applicable statutes and regulations may dictate that additonal considerations, e.g., the economic and social benefits associated with use of the chemical substance, will come into play in reaching appropriate regulatory decisions.

In order to ensure the quality and consistency of the Agency's scientific risk assessments, EPA has created the Reproductive Effects Assessment Group (REAG) in its Office of Research and Development. This group will have the responsibility for carrying out an oversight function for the Agency's risk assessment activities to ensure consistent application of mutagenicity risk assessment procedures, as well as the responsibility to conduct mutagenicity risk assessments for program offices when deemed necessary. The REAG will utilize, as appropriate, expert consultants and advisors from various Federal agencies, academia, and the private sector to assist in reviewing mutagenicity risk assessments performed by the program offices or to assist REAG in performing risk analyses at the request of the program offices.

The assessment of heritable mutagenic risk to humans involves a two-step process. First of all, the mutagenicity of the chemical must be determined, and secondly, evidence must be evaluated to determine if the chemical reaches or affects gonadal organs. Results from such an evaluation can be combined with expected human exposure information, when available, and the impact of the mutagenic risk for human populations can be estimated to the extent possible.

II. Concepts Relating to Heritable Mutagenic Risk

For the purposes of these guidelines, a mutagen is defined as a chemical substance or mixture of substances that can induce alterations in the DNA of either somatic or germinal cells of organisms. The Agency is concerned with the risk associated with both germ cell mutations and somatic mutations. Mutations carried in germ cells can be inherited by future generations and contribute to genetic disease, whereas mutations occurring in somatic cells may be implicated in the etiology of several disease states, including cancer (6,7). These guidelines, however, only concern genetic damage as it relates to germ cell mutations. The position on the use of mutagenicity test results in the assessment of carcinogenic risk has been described in the Agency's Interim Cancer Assessment Procedures (8).

The potential for mutagenic risk to germ cells can be identified on the basis of tests involving either germ or somatic cells. In the case of somatic cell tests, however, the quantitation of mutagenic risk depends on evidence that the chemical or its metabolites reaches or affects a critical target (DNA) in germinal tissue.

There are several mutagenic endpoints of concern to the Agency. These include point mutations (i.e., change in the base sequence of DNA) and structural and numerical chromosome aberrations. Structural aberrations include deficiencies, duplications, inversions, and translocations, whereas numerical aberrations refer to gains or losses of whole chromosomes (aneuploidy) or sets of chromosomes (haploidy, polyploidy). The Agency's Office of Pesticide Programs already has published various testing standards for the detection of mutagenic effects (9).

For some mutagenic mechanisms, it is conceivable that only one or a few molecules of the active compound may cause heritable changes in DNA. Mutagenic effects may also arise by mechanisms not directly related to chemical alterations of DNA, such as interference with DNA synthesis, DNA repair, or nuclear division processes.

III. Rationale for Using Nonhuman Test Systems

The virtual universality of DNA as the genetic material and of the genetic code provides a rationale for using various non-human test systems to predict the intrinsic mutagenicity of test chemicals. Additional support is provided by the observation that chemicals causing genetic effects in one species or test system frequently cause similar effects in other species or systems. Although cells of any species could theoretically be used to detect and predict genetic change in other species, certain test systems offer notable advantages, such as increased sensitivity; ease and speed of conducting the tests; low cost; anatomical, histological, and/or metabolic similarities to humans; suitability for handling large numbers of test organisms; a large data base; and a basis for characterizing genetic events.

Nonhuman test systems must be used because of the lack of suitable epidemiological data on germ cell mutations in humans. Clear epidemiological evidence for an increased mutation rate in humans due to exposure to a chemical substance is unavailable at this time. Presently only a very few of the estimated many thousands of genes in the human genome are useful as markers in determining the point mutation rates within human populations; there is a huge amount of genetic variability in the human population; and humans have a long generation time. Dominant and sex-linked recessive mutations can be detected in the first generation following treatment; however, autosomal recessive mutations and those affecting multifactorial traits largely go unnoticed because they are not recognized in the heterozygous state. Information on chromosomal aberrations induced in humans can be obtained with cytological techniques, but this information is limited. Thus, in most cases, although mutational changes occur in humans, they will be unobserved or unexpressed until future generations.

IV. Risk Assessment

A. Testing Systems

Assessing risks as a result of exposure to chemical mutagens is a complex task because of the diversity in chemical structure of mutagens and the various ways they can interfere with genetic processes. Therefore, in order to adequately assess the mutagenic potential of a chemical, data from several test systems may be needed to evaluate the ability of a chemical to produce chromosomal alterations, point mutations, and primary DNA damage (manifested by DNA repair or recombinational events). There are many testing systems currently available which can contribute information about the mutagenic potential of a test compound.

Test systems for detecting point mutations include those in bacteria, eukaryotic microorganisms, insects, and mammalian somatic cells in culture, as well as tests for detecting germinal mutations in intact mammals (e.g., the mouse specific locus test). Positive results in a mouse specific locus test argue strongly that a chemical is a potential human mutagen because the test demonstrates the mutation occurs in germinal cells and is transmitted to the next generation. However, since the development of mouse specific locus data is limited by the requirements for special strains of mice and a large number of test animals, it is not expected that many chemicals will be tested using this system. To obtain data on a large number of environmental pollutants, it will be necessary to rely on other tests to assess the risk of point mutations. Although prokaryotes, lower eukaryotes, and mammalian cells in culture do not have the ability to carry out all types of metabolic conversions that occur in intact mammals, the addition of a metabolic activation system derived from mammalian tissues has made these systems a valuable tool for detecting mutagens.

For detecting chromosomal aberrations, the following test systems have been employed: *in vitro* and *in vivo* mammalian cytogenetic tests, insect tests for heritable chromosome effects, dominant lethal tests in rodents, the heritable translocation test in rodents, and the mouse sex chromosome loss test. The heritable translocation test in rodents is among the best available tests for detecting heritable chromosomal rearrangements in mammals; the mouse X-chromosome loss test is a value in detecting the unequal distribution of chromosomal material during gametogenesis.

Other tests have been designed to detect nondisjunction (unequal distribution of chromosomes during cell division) in such diverse systems as the mouse, *Drosophila*, fungi, and mammalian cells in culture. The present data base for these systems, however, is limited at this time. Primary DNA damage which provides information bearing on the mutagenicity of a chemical can also be detected by a variety of test systems, such as unscheduled DNA repair synthesis in mammalian cells, mitotic recombination in yeast, and sister-chromatid exchange in mammalian somatic and germ cells.

The test systems mentioned above are not necessarily the only test systems that will provide the best evidence of mutagenicity. These systems are enumerated merely to demonstrate the breadth of the available techiques for assessing mutagenic potential, and to indicate the types of data which the Agency will consider in its evaluation of mutagenic potential. Most systems possess certain limitations which must be taken into account. The selection and performance of appropriate tests for evaluating the risks associated with human exposure to any suspected mutagen will depend on sound scientific judgment and experience, and may necessitate consultation with geneticists familiar with the sensitivity and experimental design of the test system in question. In view of the rapid advances in test methodology, the Agency expects that more relevant tools for predicting human mutagenic potential will become available with time. The Agency will closely monitor developments in mutagenicity evaluation and will refine its risk assessment scheme as better test systems become available.

B. Weight-of-Evidence Approach

The judgment as to whether a chemical substance is likely to be a potential human mutagen will be based on a weight-of-evidence approach that involves and considers the quality and adequacy of all the available data.

A positive response in the mouse specific locus test alone can provide strong evidence to regard a chemical as a potential human mutagen. As an alternative to the mouse specific locus test, positive responses in any two different point mutation test systems plus evidence for the presence of the test substance and/or its metabolites in mammalian gonadal organs also provides strong evidence that a compound is a potential human mutagen. Positive results in at least two systems are desirable because of the possibility of obtaining false positive or species-specific positives.

The heritable translocation test or the X chromosome loss test for chromosomal alterations in mice can provide equally strong evidence that a chemical is a potential human mutagen. Both tests detect events that are induced in treated mammals and transmitted to progeny where they are scored. In the absence of positive findings in these two test systems, positive results in two *in vivo* somatic cell cytogenetic test systems or in an *in vitro* cytogenetic test system and an *in vivo* somatic cell cytogenetic test system, coupled with evidence for the presence of the test substance and/or its metabolites in mammalian gonadal organs, will provide strong evidence that a compound is a potential human mutagen.

The test systems described here may not detect all the genetic events that are of concern to humans. Furthermore, the sensitivity of some of these systems to detect mutations is not known and may be low for certain chemical classes. Nevertheless, positive responses in these tests currently provide the best experimental evidence that a chemical has the potential to produce genetic damage in people.

If data suitable for applying the criteria just described are not available, then the chemical substance under consideration will be assessed by examining all data that give insight to its mutagenic activity. The following factors will be considered:

1. Genetic endpoints (e.g., point mutations, chromosomal mutations) detected by the test systems.
2. Sensitivity and predictive value of the test systems for various classes of chemical compounds.
3. Number of different test systems used for detecting each genetic endpoint.
4. Consistency of the results obtained in different test systems and different species.
5. Whether the tests are conducted in accordance with appropriate test protocols agreed upon by experts in the field.
6. Evidence that a chemical reaches or affects the germinal tissue, as provided by such sources as data demonstrating the alkylation of DNA or other cellular macromolecules, unscheduled DNA synthesis, sister chromatid exchange, or chromosome aberrations, in germinal cells; and non-specific accumulation of radioactive label in the gonads following administration of the labeled chemical. Other relevant evidence includes adverse gonadal effects following acute, subchronic or chronic toxicity testing; and adverse reproductive effects, such as decreased fertilization index, reduced sperm count, or abnormal sperm morphology.

Data on these factors will be used to determine whether there is strong, substantial, or only suggestive evidence that a particular chemical may be potentially mutagenic to humans.

Although definitive proof of non-mutagenicity is not possible, it seems appropriate that a chemical could be classified operationally as a non-mutagen if it gives a negative response in an adequate number of test systems that are together capable of detecting all genetic endpoints of concern, namely, point mutations, chromosomal effects, and primary DNA damage. Furthermore, if a chemical does not reach or affect gonadal organs, it can be considered not to cause heritable mutations. Stringent scientific criteria (e.g., adequate sample size, suitable experimental design, appropriate concentration range, proper controls, and adequate number of tests) should be required for acceptance of negative results to assure that the failure to detect genetic activity or the presence of the chemical in the gonadal tissue is not based on inadequacies of the test procedures.

C. Quantitative Assessment of Results

The degree of risk can be estimated by combining the preceding qualitative evaluation for mutagenicity with the potential for human exposure. When there is a lack of appropriate mutagenicity data to make a quantitative estimate, risk can still be expressed in meaningful descriptive terms. To do this, the strength of evidence that the agent possesses intrinsic mutagenic activity, that it reaches or affects gonadal organs, and the extent and pattern of human exposure to the chemical, must be examined. From these elements a judgment as to the degree of human risk may be derived. When appropriate mutagenicity data are available for making a quantitative estimate of genetic risk to humans, two major approaches are available. One approach uses only experimental data on germinal alterations induced in intact mammals. Test systems providing such data are the heritable translocation, X-chromosome loss, and specific locus tests. These tests are complete in that they directly measure genetic damage in germ cells which is observed in a subsequent generation. In this approach, information on the level of human exposure is used with experimental data on induced mutation frequency, usually obtained at much higher exposure levels. An estimate of human risk is obtained by extra polating the induced mutation frequency downward to the approximate level of anticipated human exposure. With point mutational effects, there is a strong theoretical basis for the use of the linear or no-threshold models for this extrapolation (10, 11, 12). For certain chromosomal alterations , the biological mechanisms are generally thought to fit a multiple-hit model. Other mathematical models for extrapolation should, therefore, be considered when the dose-response data are able to fit an appropriate model. Linear extrapolation of the experimental data on translocations, for example, are likely to overestimate the risks present at lower levels of exposure and a model other than the one-hit model should be considered.

The other experimental approach for assessing genetic risk uses biochemical data from intact mammals and mutagenicity data from validated test systems (13, 14, 15). The intact mammal is used primarily for relating the exposure level for a chemical to germ cell dose. This involves relating the level of mutagen-DNA interactions in germ cells to the specific exposure level by an appropriate route of administration. This information is then used with results obtained from mutagenicity test systems in which the relationship between the induction of mutations and interactions with DNA can be made. Using mutagen-DNA interactions as the common denominator, a relationship can be constructed between exposure and the induced mutation frequency. In some cases, measurements of DNA binding induced by a particular chemical agent can be determined at levels of exposures which may affect human populations, and potential human risk can be determined without the extrapolation of the data to lower levels. Such results would not require a high to low exposure level extrapolation to determine potential human risk. In those instances where the lowest experimental exposure level is greatly above those levels to which humans are exposed, it will be assumed that DNA binding is directly proportional to the exposure level unless there are compelling reasons to believe otherwise.

For some mutagenic events, DNA may not necessarily be the critical target. Interaction of chemicals with other macromolecules, such as tubulin which is involved in the separation of chromosomes during nuclear division, can lead to chromosomal nondisjunction. At present the means are not available to make strictly quantitative assessments for these types of mutagenic mechanisms. Ongoing research should provide the means to make future quantitative risk assessments for mutagens acting through these mechanisms.

In performing mutagenicity risk assessments, it is important to account for the sensitivity of the tests in detecting specific mutagenic endpoints. For example, although chemical substances which interact with DNA are likely to cause both point and chromosomal mutations, it is expected that point mutations may be relatively more frequent than chromosomal mutations at lower exposure levels. The former event can be initiated by a single interaction with DNA, whereas the latter may involve more than one interaction. Therefore, when assessing the mutagenic risk associated with low human exposures to the chemical, the point mutation data would generally be the more sensitive and appropriate information source.

Any risk assessment should clearly delineate the strengths and weakness of assumptions made, the uncertainties in the methodology, and the rationale used in reaching the conclusion, e.g., similar or different routes of exposure, metabolic difference between humans and test animals. The results should be expressed in terms of the excess of genetic disease per year or per lifetime, or the fractional increase in the assumed background spontaneous mutation rate of humans, or the radiation equivalency.

BILLING CODE 6560-32-M

[OPP-180523; PH-FRL 1668-2]

New York; Issuance of Specific Exemption for Fenvalerate on Cabbage

AGENCY: Environmental Protection Agency (EPA).

ACTION: Notice.

SUMMARY: EPA has granted a specific exemption to the New York Department of Environmental Protection (hereinafter referred to as the "Applicant") to use fenvalerate (Pydrin) on 12,000 acres of cabbage in New York to control the cabbage looper. The specific exemption is issued under the Federal Insecticide, Fungicide, and Rodenticide Act.

DATE: The specific exemption expires on November 1, 1980.

FOR FURTHER INFORMATION CONTACT: Libby Welch, Registration Division (TS-767), Office of Pesticide Programs, Environmental Protection Agency, Rm. E-124, 401 M St., SW., Washington, D.C. 20460, (202-426-0223).

SUPPLEMENTARY INFORMATION: The Applicant anticipates that an emergency situation will develop with respect to cabbage loopers on cabbage in upstate counties of New York. The Applicant contends that if the cool weather sets in during the last 35 days of cabbage growth, the cabbage looper will not be controllable. The Applicant claims that use of the pesticides registered for control of the cabbage looper is not practicable because:

1. The pesticide Phosdrin is not very effective against the pest and its residual action is short.

2. The pesticide Diazinon has not been effective in New York for many years.

3. Methomyl and *Bacillus thuringiensis* do not control the cabbage looper when temperatures are low.

4. While Monitor generally controls the pest, it may not be used within 35 days of harvest. This 35-day preharvest interval is a critical period for cabbage due to the unusually high infestation of the cabbage looper.

The Applicant estimates that the cabbage industry in New York could lose up to $12 million without adequate control.

The Applicant proposes to use fenvalerate at a rate of 0.1 to 0.2 pounds active ingredient (a.i.) per acre on up to 12,000 acres of cabbage. More than 50 percent of the fields checked in a county would have to be infested with cabbage loopers in numbers greater than one to two loopers per plant, as determined by research on Cooperative Extension personnel. Application would be made only when anticipated average daily temperature during the spray period is below 8° F during the day and/or 55–60° F at night.

EPA has determined that residues of fenvalerate in or cabbage should not exceed 2 parts per million (ppm) from the proposed use. EPA has judged this level to be adequate to protect the public health. No unreasonable hazard to the environment is anticipated from this program. Since fenvalerate is highly toxic to aquatic vertebrates and invertebrates and to bees, appropriate conditions to protect them having been imposed.

After reviewing the application and other available information, EPA has determined that the criteria for an exemption have been met. Accordingly, the Applicant has been granted a specific exemption to use the pesticide

NOTICE

The Carcinogen Assessment Group (CAG), located in the Office of Health and Environmental Assessment of EPA's Office of Research and Development, is a small group of scientists who perform an advisory assessment function for EPA's regulatory offices. The CAG analyzes existing scientific data and furnishes the regulatory offices with an evaluation of the carcinogenicity and levels of carcinogenic risk associated with chemicals in various exposure situations, as best can be determined from currently available scientific data.

The CAG reports are prepared for internal Agency use in response to EPA's regulatory office needs. They range from brief chemical profiles to very extensive evaluations, depending upon the nature of a request. The reports are used by the regulatory offices for regulatory decision making as appropriate. The reports are revised and edited based on regulatory office needs and the availability of resources.

This document was prepared at the request of the EPA Office of Air Quality Planning and Standards.

METHOD FOR DETERMINING THE UNIT RISK ESTIMATE FOR AIR POLLUTANTS

INTRODUCTION

The unit risk estimate for an air pollutant is defined as the lifetime cancer risk occurring in a hypothetical population in which all individuals are exposed continuously from birth throughout their lifetimes to a concentration of 1 ug/m^3 of the agent in the air which they breathe. This calculation is done to estimate in quantitative terms the affectiveness (potency) of the agent as a carcinogen. Unit risk estimates are used for two purposes: 1) to compare the carcinogenic potency of several agents with each other, and 2) to give a crude indication of the population risk which might be associated with air exposure to these agents, if the actual exposures are known. These two uses have different limitations.

In order to use these estimates intelligently, the nature of the source data used and the assumptions necessary to derive the estimates must be clearly understood. This appendix discusses the general approach and the assumptions common to most unit risk estimates. The credence one can ascribe to each risk estimate depends heavily on the quality of the studies on which the estimate is based and the relevance of these studies to the evaluation of air exposure in humans.

PROCEDURES FOR DETERMINATION OF UNIT RISK BASED ON BIOASSAY DATA

The data used for the quantitative estimate is one or both of two types: 1) lifetime animal studies, and 2) human studies where excess cancer risk has been associated with exposure to the agent. In animal studies it is assumed, unless evidence exists to the contrary, that if a carcinogenic response occurs at the dose levels used in the study, then responses will also occur at all lower doses with an incidence determined by the extrapolation model discussed below.

A. Choice of Model

There is no really solid scientific basis for any mathematical extrapolation model which relates carcinogen exposure to cancer risks at the extremely low concentrations that must be dealt with in evaluating environmental hazards. For practical reasons such low levels of risk cannot be measured directly either by animal experiments or by epidemiologic studies. We must, therefore, depend on our current understanding of the mechanisms of carcinogens for guidance as to which risk model to use. At the present time the dominant view of the carcinogenic process involves the concept that most agents which cause cancer also cause irreversible damage to DNA. This position is reflected by the fact that a very large proportion of agents which cause cancer are also mutagenic. There is reason to expect the quantal type of biological response that is characteristic of mutagenesis is associated with a linear non-threshold dose-response relationship. Indeed, there is substantial evidence from mutagenesis studies with both ionizing radiation and a wide variety of chemicals that this type of dose-response model is the appropriate one to use. This is particularly true at the lower end of the dose-response curve; at higher doses, there can be an upward curvature probably reflecting the effects of multistage processes on the mutagenic response. The linear non-threshold dose-response relationship is also consistent with the relatively few epidemiological studies of cancer responses to specific agents that contain enough information to make the evaluation possible (e.g., radiation induced leukemia, breast and thyroid cancer, skin cancer induced by arsenic in drinking water, liver cancer induced by aflatoxin in the diet). There is also some evidence from animal experiments that is consistent with the linear non-threshold model (e.g., liver tumors induced in mice by 2-acetylaminofluorene in the large scale ED_{01} study at the National Center for Toxicological Research and the initiation stage of the two-stage carcinogenesis model in rat liver and mouse skin).

Because it has the best, albeit limited, scientific basis of any of the current mathematical extrapolation models, the linear non-threshold model has been adopted as the primary basis for risk extrapolation to low levels of the dose-response relationship. The risk estimates made with this model should be regarded as conservative, representing the most plausible upper-limit for the risk, i.e., the true risk is not likely to be higher than the estimate, but it could be smaller.

The mathematical formulation chosen to describe the linear, non-threshold dose-response relationship at low doses is the improved multistage model developed by Dr. K. Crump. This model employs enough arbitrary constants to be able to fit almost any monotonically increasing dose-response data and it incorporates a procedure for estimating the largest possible linear slope (in the 95% confidence limit sense) at low extrapolated doses that is consistent with the data at all dose levels of the experiment.

B. Description of the Low Dose Extrapolation Model

Let P(d) represent the lifetime risk (probability) of cancer at dose d. The multistage model has the form

$$P(d) = 1 - \exp\left[-(q_0 + q_1 d + q_2 d^2 + \ldots + q_k d^k)\right]$$

where

$$q_i \geq 0, \; i = 0, 1, 2, \ldots, k$$

$$A(d) = 1 - \exp\left[-(q_1 d + q_2 d^2 + \ldots + q_k d^k)\right]$$

where

$$A(d) = \frac{P(d) - P(o)}{1 - P(o)}$$

is the extra risk over background rate at dose d.

The point estimate of the coefficients q_i, $i = 0, 1, 2, \ldots, k$ and consequently the extra risk function A(d) at any given dose d is calculated by maximizing the likelihood function of the data.

The point estimate and the 95% upper confidence limit of the extra risk A(d) are calculated by using the computer program GLOBAL 79 developed by Crump and Watson (1979). At low doses, upper 95% confidence limits on the extra risk and lower 95% confidence limits on the dose producing a given risk are determined from a 95% upper confidence limit, q_1^*, on a parameter q_1. Whenever $q_1 > 0$, at low doses the extra risk A(d) has approximately the form $A(d) = q_1 \times d$. Therefore, $q_1 \times d$ is a 95% upper confidence limit on the extra risk and R/q_1^* is a 95% lower confidence limit on the dose producing an extra risk of R. Let L_0 be the maximum value of the log-likihood function. The upper limit q_1 is calculated by increasing q_1 to a value q_1^* such that when the log-likihood is remaximized subject to this fixed value q_1^* for the linear coefficient, the resulting maximum value of the log-likihood L_1 satisfies the equation

$$2\,(L_0 - L_1) = 2.70554$$

where 2.70554 is the cumulative 90% point of the chi-square distribution with one degree of freedom, which corresponds to a 95% upper limit (one-sided). This approach of cumputing the upper confidence limit for the extra risk A(d) is an improvement on the Crump et al. (1977) model. The upper confidence limit for the extra risk calculated at low doses is always linear. This is conceptually consistent with the linear non-threshold concept discussed earlier. The slope q_1^* is taken as an upper bound of the potency of the chemical in inducing cancer at low doses.

In fitting the dose-response model, the number of terms in the polynomial is chosen equal to (h-1) where h is the number of dose groups in the experiment including the control group.

Whenever the multistage model does not fit the data sufficiently well, data at the highest dose is deleted and the model is refitted to the rest of the data. This is continued until an acceptable fit to the data is obtained. To determine whether or not a fit is acceptable, the chi-square statistic

$$X^2 = \sum_{i=1}^{h} \frac{(X_i - N_i P_i)^2}{N_i P_i (1 - P_i)}$$

is calculated where N_i is the number of animals in the i^{th} dose group, X_i is the number of animals in the i^{th} dose group with a tumor response, P_i is the probability of a response in the i^{th} dose group estimated by fitting the multistage model to the data, and h is the number of remaining groups. The fit is determined to be unacceptable whenever X^2 is larger than the cumulative 99% point of the chi-square distribution with f degree of freedom, where f equals the number of dose groups minus the number of non-zero multistage coefficients.

SELECTION OF DATA USED TO ESTIMATE PARAMETERS IN THE EXTRAPOLATION MODEL AND HUMAN EQUIVALENCE DOSE CONVERSION

For some chemicals, several studies in different animal species, strains, and sexes each run at several doses and different routes of exposure are available. A choice must be made of which of the data sets from several studies to use in the model. It is also necessary to correct for metabolism differences between species and absorption factors via different routes of administration. The procedures used in evaluating these data are consistent with the approach of making a maximum-likely risk estimate. They are listed below.

1. The tumor incidence data are separated according to organ sites or tumor types. The set of data (i.e., dose and tumor incidence) used in the model is the set where the incidence is statistically significantly higher than the control for at least one test dose level and/or where the tumor incidence rate shows a statistically significant trend with respect to dose level. The data set which gives the highest estimate of the lifetime carcinogenic risk q_1^* is selected in most cases. However, efforts are made to exclude data sets which produce spuriously high risk estimates because of a small number of animals. That is, if two sets of data show a similar dose-response relationship and one has a very small sample size, the set of data which has larger sample size is selected for calculating the carcinogenic potency.

2. If there are two or more data sets of comparable size which are identical with respect to species, strain, sex, and tumor sites, the geometric mean of q_1^*, estimated from each of these data sets, is used for risk assessment. The geometric mean of numbers A_1, A_2, ..., A_m is defined as

$$(A_1 \times A_2 \times \ldots \times A_m)^{1/m}$$

3. If two or more significant tumor sites are observed in the same study and if the data are available, the number of animals with at least one of the specific tumor sites under consideration is used as incidence data in the model.

4. Following the suggestion of Mantel and Schneiderman (1977), we assume that mg/surface area/day is an equivalent dose between species. Since, to a close approximation, the surface area is proportional to the 2/3 rds power of the weight as would be the case for a perfect sphere, the exposure in mg/day per 2/3 rds power of the weight is also considered to be an equivalent exposure. In an animal experiment this equivalent dose is computed in the following manner. Let

L_e = duration of experiment

l_e = duration of exposure

m = average dose per day in mg during administration of the agent (i.e., during l_e)

W = average weight of the experimental animal

Then, the lifetime average exposure is

$$d = \frac{l_e \times m}{L_e \times W^{2/3}}$$

Often exposures are not given in units of mg/day and it becomes necessary to convert the given exposures into mg/day. For example, in most feeding studies exposure is in terms of ppm in the diet. In this case the exposure in mg/day is

$$m = \text{ppm} \times F \times r$$

where ppm is parts per million in the diet of the carcinogenic agent, F is the weight of the food consumed per day in kg, and r is the absorption fraction. In the absence of any data to the contrary, r is assumed to be equal to one. For a uniform diet, the weight of the food consumed is proportional to the calories required which, in turn, is proportional to the surface area or 2/3rds power of the weight, so that

$$m \propto ppm \times W^{2/3} \times r$$

or

$$\frac{m}{rW^{2/3}} \propto ppm$$

As a result, ppm in the diet is often assumed to be an equivalent exposure between species. However, we feel that this is not justified since the calories/kg of food is very different in the diet of man compared to laboratory animals primarily due to moisture content differences. Instead we use an empirically derived food factor $f = F/W$ which is the fraction of a species body weight that is consumed per day as food. We use the rates given below.

Species	W	f
Man	70	0.028
Rat	0.35	0.05
Mice	0.03	0.13

Thus, when the exposure is given as a certain dietary concentration in ppm the exposure in $mg/W^{2/3}$ is

$$\frac{m}{r \times W^{2/3}} = \frac{ppm \times F}{W^{2/3}} = \frac{ppm \times f \times W}{W^{2/3}} = ppm \times f \times W^{1/3}$$

When exposure is given in terms of mg/kg/day = $m/Wr = s$, the conversion is simply

$$\frac{m}{rW^{2/3}} = s \times W^{1/3}$$

When exposure is via inhalation, the calculation of dose can be considered for two cases where 1) the carcinogenic agent is either a completely water soluble gas or an aerosal, and is absorbed proportionally to the amount of air breathed in, and 2) where the carcinogen is a poorly water soluble gas which reaches an equilibrium between the air breathed and the body compartments. After equilibrium is reached, the rate of absorption of these agents is expected to be proportional to the metabolic rate which, in turn, is proportional to the rate of oxygen consumption which, in turn, is a function of surface area.

Case 1

Agents that are in the form of particulate matter or virtually completely absorbed gases such as SO_2 can reasonably be expected to be absorbed proportional to the breathing rate. In this case the exposure in mg/day may be expressed as

$$m = I \times v \times r$$

where I = inhalation rate per day in m^3, v = mg/m^3 of the agent in air, and r = the absorption fraction.

The inhalation rates, I, for various species can be calculated from the observations (FASEB 1974) that 25 g mice breathe 34.5 liters/day and 113 g rats breathe 105 liters/day. For mice and rats of other weights, W (in kilograms), the surface area proportionality can be used to find breathing rates in m^3/day as follows:

$$\text{For mice, } I = 0.0345\ (W/0.025)^{2/3}\ m^3/\text{day}$$

$$\text{For rats, } I = 0.105\ (W/0.113)^{2/3}\ m^3/\text{day}$$

For humans, the values of 20 m^3/day* is adopted as a standard breathing rate (ICRP 1977).

The equivalent exposure in mg/$W^{2/3}$ for these agents can be derived from the air intake data in way analogous to the food intake data. The empirical factors for the air intake per kg per day, $i = I/W$ based upon the previous stated relationships are tabulated below.

Species	W	i = I/W
Man	70	0.29
Rat	0.35	0.64
Mice	0.03	1.3

Therefore, for particulates or completely absorbed gases, the equivalent exposure in mg/$W^{2/3}$ is

$$d = \frac{m}{W^{2/3}} = \frac{Ivr}{W^{2/3}} = \frac{iWvr}{W^{2/3}} = iW^{1/3}\ vr$$

In the absence of experimental information or a sound theoretical argument to the contrary, the fraction absorbed, r, is assumed to be the same for all species.

---

*From "Recommendation of the International Commission on Radiological Protection," page 9. The average breathing rate is 10^7 cm^3 per 8-hour workday and 2×10^7 cm^3 in 24 hours.

Case 2

The dose in mg/day of partially soluble vapors is proportional to the O_2 consumption, which, in turn, is proportional to $W^{2/3}$ and is also proportional to the solubility of the gas in body fluids, which can be expressed as an absorption coefficient r for the gas. Therefore, expressing the O_2 consumption as $O_2 = k\ W^{2/3}$ where k is a constant independent of species, it follows that

$$m = k\ W^{2/3} \times v \times r$$

or

$$d = \frac{m}{W^{2/3}} = kvr$$

As with Case 1, in the absense of experimental information or a sound theoretical argument to the contrary, the absorption fraction, r, is assumed to be the same for all species. Therefore, for these substances a certain concentration in ppm or ug/m^3 in experimental animals is equivalent to the same concentration in humans. This is supported by the observation that the minimum alveolar concentration necessary to produce a given "stage" of anesthesia is similar in man and animals (Dripps et al. 1977). When the animals are exposed via the oral route and human exposure is via inhalation or vice-versa, the assumption is made, unless there is pharmacokinetic evidence to the contrary, that absorption is equal by either exposure route.

5. If the duration of experiment (Le) is less than the natural lifespan of the test animal (L), the slope q_1^*, or more generally the exponent g(d), is increased by multiplying a factor $(L/L_e)^3$. We assume that if the average dose, d, is continued, the age-specific rate of cancer will continue to increase as a constant function of the background rate. The age-specific rates for humans increases at least by the 2nd power of the age and often by a considerably higher power as demonstrated by Doll (1971). Thus, we would expect

the cumulative tumor rate to increase by at least the 3rd power of age. Using this fact, we assume that the slope q_1^*, or more generally the exponent g(d), would also increase by at least the 3rd power of age. As a result, if the slope q_1^* [or g(d)] is calculated at age L_e, we would expect that if the experiment had been continued for the full lifespan, L, at the given average exposure, the slope q_1^* [or g(d)] would have been increased by at least $(L/L_e)^3$.

This adjustment is conceptually consistent to the proportional hazard model proposed by Cox (1972) and the time-to-tumor model considered by Crump et al. (1979) where the probability of cancer by age t and at dose d is given by

$$P(d,t) = 1 - \exp[-f(t) \times g(d)]$$

CALCULATION OF THE UNIT RISK

The risk associated with d mg/kg$^{2/3}$/day is obtained from GLOBAL 79 and, for most cases of interest to risk assessment, can be adequately approximated by $P(d) = 1 - \exp(-q_1^*d)$. A "unit risk" in units X is simply the risk corresponding to an exposure of X = 1. To estimate this value we simply find the number of mg/kg$^{2/3}$/day corresponding to one unit of X and substitute this value into the above relationship. Thus, for example, if X is in units of ug/m^3 in the air, we have that for case (1) $d = 0.29 \times 70^{1/3} \times 10^{-3}$ mg/kg$^{2/3}$/day and for case (2) d = 1, when ug/m^3 is the unit used to compute parameters in animal experiment.

If exposures are given in terms of ppm in air we may simply use the fact that

$$1 \text{ ppm} = 1.2 \times \frac{\text{molecular weight (gas)}}{\text{molecular weight (air)}} \text{ mg/m}^3$$

Note, an equivalent method of calculating unit risk would be to use mg/kg for the animal exposures and then increase the jth polynomial coefficient by an amount

$$(W_h/W_a)^{j/3} \qquad j = 1, 2, \ldots, k$$

and use mg/kg equivalents for the unit risk values.

ESTIMATION OF UNIT RISK BASED ON HUMAN DATA

If human epidemiology studies and sufficiently valid exposure information are available for the compound, they are always used in some way. If they show a carcinogenic effect, the data are analyzed to give an estimate of the linear dependence of cancer rates on lifetime average dose, which is equivalent to the factor B_H. If they show no carcinogenic effect when positive animal evidence is available, then it is assumed that a risk does exist but it is smaller than could have been observed in the epidemiology study, and an upper-limit of the cancer incidence is calculated assuming hypothetically that the true incidence is just below the level of detection in the cohort studied, which is determined largely by the cohort size. Whenever possible, human data are used in preference to animal bioassay data.

In human studies, the response is measured in terms of the relative risk of the exposed cohort of individuals compared to the control group. In the analysis of this data it is assumed that the excess risk, or relative risk minus one, $R(X_1) - 1$, is proportional to the lifetime average exposure, X_1, and that it is the same for all ages. It follows that the lifetime risk in the general population exposed to a lifetime average concentration X_2, $P(X_2)$, is equal to $[R(X_1) - 1]X_2/X_1$ multiplied by the lifetime risk at that site in the general population. The unit risk estimate is the value of P when X_2 is 1 ug/m^3. Except for an unusually well-documented human study, the confidence limit for the excess risk P is not calculated, due to the difficulty of accounting for the uncertainty inherent in the data (exposure and cancer response).

INTERPRETATION OF UNIT RISK

The unit risk estimate is a rough indication of the relative potency of a given agent compared with other carcinogens. The comparative potency of different agents is more reliable when the comparison is based on studies in the same test species, strain, and sex and by the same route of exposure, preferably by inhalation.

For several reasons the unit risk estimate is only an approximate indication of the absolute risk in populations exposed to known air concentrations. First, there are important species differences in uptake, metabolism, and organ distribution of carcinogens, as well as species differences in target site susceptibility, immunological responses, hormone function, dietary factors, and disease. Secondly, the concept of equivalent doses for humans compared to animals on a mg/surface area basis is virtually without experimental verification regarding carcinogenic response. Finally, human populations are variable with respect to genetic constitution and diet, living environment, activity patterns, and other cultural factors.

Environmental Protection Agency

Water Quality Criteria Documents; Availability

ENVIRONMENTAL PROTECTION AGENCY

[FRL 1623-3]

Water Quality Criteria Documents; Availability

AGENCY: Environmental Protection Agency.

ACTION: Notice of Water Quality Criteria Documents.

SUMMARY: EPA announces the availability and provides summaries of water quality criteria documents for 64 toxic pollutants or pollutant categories. These criteria are published pursuant to section 304(a)(1) of the Clean Water Act.

AVAILABILITY OF DOCUMENTS: Summaries of both aquatic-based and health-based criteria from the documents are published below. Copies of the complete documents for individual pollutants may be obtained from the National Technical Information Service (NTIS), 5285 Port Royal Road, Springfield, VA 22161, (703-487-4650). A list of the NTIS publication order numbers for all 64 criteria documents is published below. These documents are also available for public inspection and copying during normal business hours at: Public Information Reference Unit, U.S. Environmental Protection Agency, Room 2404 (rear), 401 M St., S.W., Washington, D.C. 20460. As provided in 40 CFR Part 2, a reasonable fee may be charged for copying services. Copies of these documents are also available for review in the EPA Regional Office libraries.

Copies of the documents are not available from the EPA office listed below. Requests sent to that office will be forwarded to NTIS or returned to the sender.

SUPPLEMENTARY INFORMATION:

Background

Pursuant to section 304(a)(1) of the Clean Water Act, 33 U.S.C. 1314(a)(1), EPA is required to periodically review and publish criteria for water quality accurately reflecting the latest scientific knowledge:

> (A) on the kind and extent of all identifiable effects on health and welfare including, but not limited to, plankton, fish, shellfish, wildlife, plant life, shorelines, beaches, esthetics, and recreation which may be expected from the presence of pollutants in any body of water, including groundwater, (B) on the concentration and dispersal of pollutants, or their byproducts, through biological, physical, and chemical processes, and (C) on the effects of pollutants on biological community diversity, productivity, and stability, including information on the factors affecting rates of eutrophication and rates of organic and inorganic sedimentation for varying types of receiving waters.

EPA is today announcing the availability of criteria documents for 64 of the 65 pollutants designated as toxic under section 307(a)(1) of the Act. The document on TCDD (Dioxin) will be published within the next month after review of recent studies. Criteria for the section 307(a)(1) toxic pollutants being published today will replace the criteria for those same pollutants found in the EPA publication, *Quality Criteria for Water,* (the "Red Book.") Criteria for all other pollutants and water constituents found in the "Red Book" remain valid. The criteria published today have been derived using revised methodologies for determining pollutant concentrations that will, when not exceeded, reasonably protect human health and aquatic life. Draft criteria documents were made available for public comment (44 FR 15926, March 15, 1979, 44 FR 43660, July 25, 1979, 44 FR 56628, October 1, 1979). These final criteria have been derived after consideration of all comments received.

These criteria documents are also issued in satisfaction of the Settlement Agreement in *Natural Resources Defense Council, et al.* v. *Train,* 8 E.R.C. 2120 (1976), modified, 12 E.R.C. 1833 (D.D.C. 1979). Pursuant to paragraph 11 of that agreement, EPA is required to publish criteria documents for the 65 pollutants which Congress, in the 1977 amendments to the Act, designated as toxic under section 307(a)(1). These documents contain recommended maximum permissible pollutant concentrations consistent with the protection of aquatic organisms, human health, and some recreational activities. Although paragraph 11 imposes certain obligations on the Agency, it does not create additional authority.

The Development of Water Quality Criteria

Section 304(a)(1) criteria contain two essential types of information: (1) discussions of available scientific data on the effects of pollutants on public health and welfare, aquatic life and recreation, and (2) quantitative concentrations or qualitative assessments of the pollutants in water which will generally ensure water quality adequate to support a specified water use. Under section 304(a)(1), these criteria are based solely on data and scientific judgments on the relationship between pollutant concentrations and environmental and human health effects. Criteria values do not reflect considerations of economic or technological feasibility.

Publication of water quality criteria of this type has been an ongoing process which EPA, and its predecessor Agency, the Federal Water Pollution Control Administration, have been engaged in since 1968. At that time the first Federal compilation of water quality criteria, the so-called "Green Book" *(Water Quality Criteria)*, was published. As now, these criteria contained both narrative discussions of the environmental effects of pollutants on a range of possible uses and concentrations of pollutants necessary to support these uses. Since that time, water quality criteria have been revised and expanded with publication of the "Blue Book" *(Water Quality Criteria 1972)* in 1973 and the "Red Book" *(Quality Criteria for Water)* in 1976.

Since publication of the Red Book there have been substantial changes in EPA's approach to assessing scientific data and deriving section 304(a)(1) criteria. Previous criteria were derived from a limited data base. For many pollutants, an aquatic life criterion was derived by multiplying the lowest concentration known to have acute lethal effect on half of a test group of an aquatic species (the LC50 value) by an application factor in order to protect against chronic effects. If data showed a substance to be bioaccumulative or to have other significant long-term effects, a factor was used to reduce the indicated concentrations to a level presumed to be protective. Criteria for the protection of human health were similarly derived by considering the pollutants' acute, chronic, and bioaccumulative effects on non-human mammals and humans.

Although a continuation of the process of criteria development, the criteria published today were derived using revised methodologies (Guidelines) for calculating the impact of pollutants on human health and aquatic organisms. These Guidelines consist of systematic methods for assessing valid and appropriate data concerning acute and chronic adverse effects of pollutants on aquatic organisms, non-human mammals, and humans. By use of these data in prescribed ways, criteria are formulated to protect aquatic life and human health from exposure to the pollutants. For some pollutants, bioconcentration properties are used to formulate criteria protective of aquatic life uses. For almost all of the pollutants, bioconcentration properties are used to assess the relative extent of human exposure to the pollutant either directly through ingestion of water or indirectly through consumption of aquatic organisms. Human health criteria for carcinogens are presented as incremental risks to man associated with specific concentrations of the pollutant in ambient water. The Guidelines used to derive criteria protective of aquatic life and human health are fully described in appendices B and C, respectively, of this Notice.

The Agency believes that these Guidelines provide criteria which more accurately reflect the effects of these pollutants on human health and on aquatic organisms and their uses. They are based on a more rational and consistent approach for using scientific data. These Guidelines were developed by EPA scientists in consultation with scientists from outside the Agency and they have been subjected to intensive public comment.

Neither the Guidelines nor the criteria are considered inflexible doctrine. Even at this time, EPA is taking action to employ the resources of peer review groups, including the Science Advisory Board, to evaluate recently published data, and EPA is conducting its own evaluation of new data to determine whether revisions to the criteria documents would be warranted.

The criteria published today are based solely on the effect of a single pollutant. However, pollutants in combination may have different effects because of synergistic, additive, or antagonistic properties. It is impossible in these documents to quantify the combined effects of these pollutants, and persons using criteria should be aware that site-specific analysis of actual combinations of pollutants may be necessary to give more precise indications of the actual environmental impacts of a discharge.

Relationship of the Section 304(a)(1) Criteria to Regulatory Programs

Section 304(a)(1) criteria are not rules and they have no regulatory inpact. Rather, these criteria present scientific data and guidance on the environmental effect of pollutants which can be useful to derive regulatory requirements based on considerations of water quality impacts. Under the Clean Water Act, these regulatory requirements may include the promulgation of water quality-based effluent limitations under section 302, water quality standards under section 303, or toxic pollutant effluent standards under section 307. States are encouraged to begin to modify or, if necessary, develop new programs necessary to support the implementation of regulatory controls for toxic pollutants. As appropriate, States may incorporate criteria for toxic pollutants, based on this guidance, into their water quality standards.

Section 304(a)(1) criteria have been most closely associated with the development of State water quality standards, and the "Red Book" values have, in the past, been the basis for EPA's assessments of the adequacy of State requirements. However, EPA is now completing a major review of its water quality standards policies and regulations. After consideration of comments received on an Advance Notice of Proposed Rulemaking (43 FR 29588, July 10, 1978) and the draft criteria documents, the Agency intends to propose, by the end of this year, a revised water quality standards regulation which will clarify the Agency's position on a number of significant standards issues.

With the publication of these criteria, however, it is appropriate to discuss EPA's current thinking on standards issues relating to their use. This discussion does not establish new regulatory requirements and is intended as guidance on the possible uses of these criteria and an indication of future rulemaking the Agency may undertake. No substantive requirements will be established without further opportunity for public comment.

Water Quality Standards

Section 303 of the Clean Water Act provides that water quality standards be developed for all surface waters. A water quality standard consists basically of two parts: (1) A "designated use" for which the water body is to be protected (such as "agricultural," "recreation" or "fish and wildlife"), and (2) "criteria" which are numerical pollutant concentration limits or narrative statements necessary to preserve or achieve the designated use. A water quality standard is developed through State or Federal rulemaking proceedings and must be translated into enforceable effluent limitations in a point source (NPDES) permit or may form the basis of best management practices applicable to nonpoint sources under section 208 of the Act.

Relationship of Section 304(a)(1) Criteria to the Criteria Component of State Water Quality Standards:

In the ANPRM, EPA announced a policy of "presumptive applicability" for section 304(a)(1) criteria codified in the "Red Book." Presumptive applicability meant that a State had to adopt a criterion for a particular water quality parameter at least as stringent as the recommendation in the Red Book unless the State was able to justify a less stringent criterion based on: natural background conditions, more recent scientific evidence, or local, site-specific information. EPA is rescinding the policy of presumptive applicability because it has proven to be too inflexible in actual practice.

Although the section 304(a)(1) criteria represent a reasonable estimate of pollutant concentrations consistent with the maintenance of designated water uses, States may appropriately modify these values to reflect local conditions. In certain circumstances, the criteria may not accurately reflect the toxicity of a pollutant because of the effect of local water quality characteristics or varying sensitivities of local populations. For example, in some cases, ecosystem adaptation may enable a viable, balanced aquatic population to exist in waters with high natural background levels of certain pollutants. Similarly, certain compounds may be more or less toxic in some waters because of differences in alkalinity, temperature, hardness, and other factors.

Methods for adjusting the section 304(a)(1) criteria to reflect these local differences are discussed below.

Relationship of Section 304(a)(1) Criteria to Designated Water Uses:

The criteria published today can be used to support the designated uses which are generally found in State standards. The following section discusses the relationship between the criteria and individual use classifications. Where a water body is designated for more than one use, criteria necessary to protect the most sensitive use should be applied.

1. *Recreation.* Recreational uses of water include such activities as swimming, wading, boating and fishing. Although insufficient data exist on the effects of toxic pollutants resulting from exposure through such primary contact as swimming, section 304(a)(1) criteria based on human health effects may be used to support this designated use where fishing is included in the State definition of "recreation." In this situation only the portion of the criterion based on fish consumption should be used.

2. *Protection and Propagation of Fish and Other Aquatic Life:* The section 304(a)(1) criteria based on toxicity to aquatic life may be used directly to support this designated use.

3. *Agricultural and Industrial Uses:* The section 304(a)(1) criteria were not specifically developed to reflect the impact of pollutants on agricultural and industrial uses. However, the criteria developed for human health and aquatic life are sufficiently stringent to protect these other uses. States may establish criteria specifically designed to protect these uses.

4. *Public Water Supply:* The drinking water exposure component of the human health effects criteria can apply directly to this use classification or may be appropriately modified depending upon whether the specific water supply system falls within the auspices of the Safe Drinking Water Act's (SDWA) regulatory control, and the type and level of treatment imposed upon the supply before delivery to the consumer. The SDWA controls the presence of toxic pollutants in finished ("end-of-tap") drinking water. A brief description of relevant sections of this Act is necessary to explain how the SDWA will work in conjunction with section 304(a)(1) criteria in protecting human health from the effects of toxics due to consumption of water.

Pursuant to section 1412 of the SDWA, EPA has promulgated "National Interim Primary Drinking Water Standards" for certain organic and inorganic substances. These standards establish "maximum contaminant levels" ("MCLs") which specify the maximum permissible level of a contaminant in water which may be delivered to a user of a public water system now defined as serving a minimum of 25 people. MCLs are established based on consideration of a range of factors including not only the health effects of the contaminants but also technological and economic feasibility of the contaminants' removal from the supply. EPA is required to establish revised primary drinking water regulations based on the effects of a contaminant on human health, and include treatment capability, monitoring availability, and costs. Under Section 1401(1)(D)(i) of the SDWA, EPA is also allowed to establish the minimum quality criteria for water which may be taken into a public water supply system.

Section 304(a)(1) criteria provide estimates of pollutant concentrations protective of human health, but do not consider treatment technology, costs and other feasibility factors. The section 304(a)(1) criteria also include fish bioaccumulation and consumption factors in addition to direct human drinking water intake. These numbers were not developed to serve as "end of tap" drinking water standards, and they have no regulatory significance under the SDWA. Drinking water standards are established based on considerations, including technological and economic feasibility, not relevant to section 304(a)(1) criteria. Section 304(a)(1) criteria may be analogous to the recommended maximum contaminant levels (RMCLs) under section 1412(b)(1)(B) of the SDWA in which, based upon a report from the National Academy of Sciences, the Administrator should set target levels for contaminants in drinking water at which "no known or anticipated adverse effects occur and which allows an adequate margin of safety". RMCLs do not take treatment, cost, and other feasibility factors into consideration. Section 304(a)(1) criteria are, in concept, related to the health-based goals specified in the RMCLs. Specific mandates of the SDWA such as the consideration of multi-media exposure, as well as different methods for setting maximum contaminant levels under the two Acts, may result in differences between the two numbers.

MCLs of the SDWA, where they exist, control toxic chemicals in finished drinking water. However, because of variations in treatment and the fact that only a relatively small number of MCLs have been developed, ambient water criteria may be used by the States as a supplement to SDWA regulations. States will have the option of applying MCLs, section 304(a)(1) human health effects criteria, modified section 304(a)(1) criteria or controls more stringent than these three to protect against the effects of toxic pollutants by ingestion from drinking water.

For untreated drinking water supplies, States may control toxics in the ambient water through either use of MCLs (if they exist for the pollutants of concern), section 304(a)(1) human health effects criteria, or a more strigent contaminant level than the former two options.

For treated drinking water supplies serving less than 25 people, States may choose toxics control through application of MCLs (if they exist for the pollutants of concern and are attainable by the type of treatment) in the finished drinking water. States also have the options to control toxics in the ambient water by choosing section 304(a)(1.) criteria, adjusted section 304(a)(1) criteria resulting from the reduction of the direct drinking water exposure component in the criteria calculation to the extent that the treatment procedure reduces the level of pollutants, or a more stringent contaminant level than the former three options.

For treated drinking water supplies serving 25 people or greater, States *must* control toxics down to levels at least as stringent as MCLs (where they exist for the pollutants of concern) in the finished drinking water. However, States also have the options to control toxics in the ambient water by choosing section 304(a)(1) criteria, adjusted section 304(a)(1) criteria resulting from the reduction of the direct drinking water exposure component in the criteria calculation to the extent that the treatment process reduces the level of pollutants, or a more stringent contaminant level than the former three options.

Inclusion of Specific Pollutants in State Standards:

To date, EPA has not required that a State address any specific pollutant in its standards. Although all States have established standards for most conventional pollutants, the treatment of toxic pollutants has been much less extensive. In the ANPRM, EPA suggested a policy under which States would be required to address a set of pollutants and incorporate specific toxic pollutant criteria into water quality standards. If the State failed to incorporate these criteria, EPA would promulgate the standards based upon these criteria pursuant to section 303(c)(4)(B).

In the forthcoming proposed revision to the water quality standard regulations, a significant change in policy will be proposed relating to the incorporation of certain pollutants in State water quality standards. This proposal will differ from the proposal made in the ANPRM. The ANPRM proposed an EPA-published list of pollutants for which States would have had to develop water quality standards. This list might have contained some (or all) of the 65 toxic pollutants. However, the revised water quality standards regulation will propose a process by which EPA will assist States in identifying specific toxic pollutants required for assessment for possible inclusion in State water quality standards. For these pollutants, States will have the option of adopting the published criteria or of adjusting those criteria based on site-specific analysis.

These pollutants would generally represent the greatest threat to sustaining a healthy, balanced ecosystem in water bodies or to human health due to exposure directly or indirectly from water. EPA is currently developing a process to determine which pollutants a State must assess for possible inclusion in its water quality standards. Relevant factors might include the toxicity of the pollutant, the frequency and concentration of its discharge, its geographical distribution, the breadth of data underlying the scientific assessment of its aquatic life and human health effects, and the technological and economic capacity to control the discharge of the pollutant. For some of the pollutants, all States may be required to assess them for possible inclusion in their standards. For others, assessment would be restricted to States or limited to specific water bodies where the pollutants pose a particular site-specific problem.

Criteria Modification Process

Flexibility is available in the application of these and any other valid water quality criteria to regulatory programs. Although in some cases they may be used by the States as developed, the criteria may be modified to refect local environmental conditions and human exposure patterns before incorporation into programs such as water quality standards. If significant impacts of site-specific water quality conditions in the toxicities of pollutants can be demonstrated or significantly different exposure patterns of these pollutants to humans can be shown, section 304(a)(1) criteria may be modified to reflect these local conditions. The term "local" may refer to any appropriate geographic area where common aquatic environmental conditions or exposure patterns exist. Thus, "local" may signify a Statewide, regional, river reach, or entire river basin area. On the other hand, the criteria of some pollutants might be applicable nationwide without the need for adaptation to reflect local conditions. The degree of toxicity toward aquatic organisms and humans characteristic of these pollutants would not change significantly due to local water quality conditions.

EPA is examining a series of environmental factors or water quality parameters which might realistically be expected to affect the laboratory-derived water quality criterion recommendation for a specific pollutant. Factors such as hardness, pH, suspended solids, types of aquatic organisms present, etc. could impact on the chemical's effect in the aquatic environment. Therefore, local information can be assembled and analyzed to adjust the criterion recommendation if necessary.

The Guidelines for deriving criteria for the protection of aquatic life suggest several approaches for modifying the criteria. First, toxicity data, both acute and chronic, for local species could be substituted for some or all of the species used in deriving criteria for the water quality standard. The minimum data requirements should still be fulfilled in calculating a revised criterion. Second, criteria may be specifically tailored to a local water body by use of data from toxicity tests performed with that ambient water. A procedure such as this would account for local environmental conditions in formulating a criterion relevant to the local water body. Third, site-specific water quality characteristics resulting in either enhancement or mitigation of aquatic life toxicity for the pollutant could be factored into final formulation of the criterion. Finally, the criteria may be made more stringent to ensure protection of an individual species not otherwise adequately protected by any of the three modification procedures previously mentioned.

EPA does not intend to have States assess every local stream segment and lake in the country on an individual basis before determining if an adjustment is necessary. Rather, it is envisioned that water bodies having similar hydrological, chemical, physical, and biological properties will be grouped for the purpose of criteria adjustment. The purpose of this effort is to assist States in adapting the section 304(a) criteria to local conditions where needed, thereby precluding the setting of arbitrary and perhaps unnecessarily stringent or underprotective criteria in a water body. In all cases, EPA will still be required, pursuant to section 303(c), to determine whether the State water quality standards are consistent with the goals of the Act, including a determination of whether State-established criteria are adequate to support a designated use.

Criteria for the Protection of Aquatic Life

Interpretation of the Criteria

The aquatic life criteria issued today are summarized in Appendix A of this **Federal Register** notice. Criteria have been formulated by applying a set of Guidelines to a data base for each pollutant. The criteria for the protection of aquatic life specify pollutant concentrations which, if not exceeded, should protect most, but not necessarily all, aquatic life and its uses. The Guidelines specify that criteria should be based on an array of data from organisms, both plant and animal, occupying various trophic levels. Based on these data, criteria can be derived which should be adequate to protect the types of organisms necessary to support an aquatic community.

The Guidelines are not designed to derive criteria which will protect all life stages of all species under all conditions. Generally some life stage of one or more tested species, and probably some untested species, will have sensitivities below the maximum value or the 24-hour average under some conditions and would be adversely affected if the highest allowable pollutant concentrations and the worst conditions existed for a long time. In actual practice, such a situation is not likely to occur and thus the aquatic community as a whole will normally be protected if the criteria are not exceeded. In any aquatic community there is a wide range of individual species sensitivities to the effects of toxic pollutants. A criterion adequate to protect the most susceptible life stage of the most sensitive species would in many cases be more stringent than necessary to protect the overall aquatic community.

The aquatic life criteria specify both maximum and 24-hour average values. The combination of the two values is designed to provide adequate protection of aquatic life and its uses from acute and chronic toxicity and bioconcentration without being as restrictive as a one-number criterion would have to be to provide the same amount of protection. A time period of 24 hours was chosen in order to ensure that concentrations not reach harmful levels for unacceptably long periods. Averaging for longer periods, such as a week or a month for example, could permit high concentrations to persist long enough to produce significant adverse effects. A 24-hour period was chosen instead of a slightly longer or shorter period in recognition of daily fluctuations in waste discharges and of the influence of daily cycles of sunlight and darkness and temperature on both pollutants and aquatic organisms.

The maximum value, which is derived from acute toxicity data, prevents significant risk of adverse impact to organisms exposed to concentrations above the 24-hour average. Merely specifying the average value over a specified time period is insufficient because concentrations of chemicals higher than the average value can kill or cause irreparable damage in short periods. Furthermore, for some chemicals the effect of intermittent high exposures is cumulative. It is therefore necessary to place an upper limit on pollutant concentrations to which aquatic organisms might be exposed. The two-number criterion is intended to describe the highest average ambient water concentration which will produce a water quality generally suited to the maintenance of aquatic life while restricting the extent and duration of the excursions over that average to levels which will not cause harm. The only way to assure the same degree of protection with a one-number criterion would be to use the 24-hour average as a concentration that is not to be exceeded at any time in any place.

Since some substances may be more toxic in freshwater than in saltwater, or vice versa, provision is made for deriving separate water quality criteria for freshwater and for saltwater for each substance. However, for some substances sufficient data may not be available to derive one or both of these criteria using the Guidelines.

Specific aquatic life criteria have not been developed for all of the 65 toxic pollutants. In those cases where there were insufficient data to allow the derivation of a criterion, narrative descriptions of apparent threshold levels for acute and/or chronic effects based on the available data are presented. These descriptions are intended to convey a sense of the degree of toxicity of the pollutant in the absence of a criterion recommendation.

Summary of the Aquatic Life Guidelines

The Guidelines for Deriving Water Quality Criteria for the Protection of Aquatic Life and its Uses were developed to describe an objective, internally consistent, and appropriate way of ensuring that water quality criteria for aquatic life would provide, on the average, a reasonable amount of protection without an unreasonable amount of overprotection or underprotection. The resulting criteria are not intended to provide 100 percent protection of all species and all uses of aquatic life all of the time, but they are intended to protect most species in a balanced, healthy aquatic community. The Guidelines are published as Appendix B of this Notice. Responses to public comments on these Guidelines are attached as Appendix D.

Minimum data requirements are identified in four areas: acute toxicity to animals (eight data points), chronic toxicity to animals (three data points), toxicity to plants, and residues. Guidance is also given for discarding poor quality data.

Data on acute toxicity are needed for a variety of fish and invertebrate species and are used to derive a Final Acute Value. By taking into account the number and relative sensitivities of the tested species, the Final Acute Value is designed to protect most, but not necessarily all, of the tested and untested species.

Data on chronic toxicity to animals can be used to derive a Final Chronic Value by two different means. If chronic values are available for a specified number and array of species, a final chronic value can be calculated directly. If not, an acute-chronic ratio is derived and then used with the Final Acute Value to obtain the Final Chronic Value.

The Final Plant Value is obtained by selecting the lowest plant toxicity value based on measured concentrations.

The Final Residue Value is intended to protect wildlife which consume aquatic organisms and the marketability of aquatic organisms. Protection of the marketability of aquatic organisms is, in actuality, protection of a use of that water body ("commercial fishery"). Two kinds of data are necessary to calculate the Final Residue Value: a bioconcentration factor (BCF) and a maximum permissible tissue concentration, which can be an FDA action level or can be the result of a chronic wildlife feeding study. For lipid soluble pollutants, the BCF is normalized for percent lipids and then the Final Residue Value is calculated by dividing the maximum permissible tissue concentration by the normalized BCF and by an appropriate percent lipid value. BCFs are normalized for percent lipids since the BCF measured for any individual aquatic species is generally proportional to the percent lipids in that species.

If sufficient data are available to demonstrate that one or more of the final values should be related to a water quality characteristic, such as salinity, hardness, or suspended solids, the final value(s) are expressed as a function of that characteristic.

After the four final values (Final Acute Value, Final Chronic Value, Final Plant Value, and Final Residue Value) have been obtained, the criterion is established with the Final Acute Value becoming the maximum value and the lowest of the other three values becoming the 24-hour average value. All of the data used to calculate the four final values and any additional pertinent information are then reviewed to determine if the criterion is reasonable. If sound scientific evidence indicates that the criterion should be raised or lowered, appropriate changes are made as necessary.

The present Guidelines have been revised from the earlier published versions (43 FR 21506, May 18, 1978; 43 FR 29028, July 5, 1978; 44 FR 15926, March 15, 1979). Details have been added in many places and the concept of a minimum data base has been incorporated. In addition, three adjustment factors and the species sensitivity factor have been deleted. These modifications were the result of the Agency's analysis of public comments and comments received from the Science Advisory Board on earlier versions of the Guidelines. These comments and the Resultant modifications are addressed fully in Appendix D to this notice.

Criteria for the Protection of Human Health

Interpretation of the Human Health Criteria

The human health criteria issued today are summarized in Appendix A of this **Federal Register** notice. Criteria for the protection of human health are presented for 62 of the 65 pollutants based on their carcinogenic, toxic, or organoleptic (taste and odor) properties. The meanings and practical uses of the criteria values are distinctly different depending on the properties on which they are based.

The objective of the health assessment portions of the criteria documents is to estimate ambient water concentrations which, in the case of non-carcinogens, prevent adverse health effects in humans, and in the case of suspect or proven carcinogens, represent various levels of incremental cancer risk.

Health assessments typically contain discussions of four elements: Exposure, pharmacokinetics, toxic effects, and criterion formulation.

The exposure section summarizes information on exposure routes: ingestion directly from water, indirectly from consumption of aquatic organisms found in ambient water, other dietary sources, inhalation, and dermal contact. Exposure assumptions are used to derive human health criteria. Most criteria are based solely on exposure from consumption of water containing a specified concentration of a toxic pollutant and through consumption of aquatic organisms which are assumed to have bioconcentrated pollutants from the water in which they live. Other multimedia routes of exposure such as air, non-aquatic diet, or dermal are not factored into the criterion formulation for the vast majority of pollutants due to lack of data. The criteria are calculated using the combined aquatic exposure pathway and also using the aquatic organism ingestion exposure route alone. In criteria reflecting both the water consumption and aquatic organism ingestion routes of exposure, the relative exposure contribution varies with the propensity of a pollutant to bioconcentrate, with the consumption of aquatic organisms becoming more important as the bioconcentration factor (BCF) increases. As additional information on total exposure is assembled for pollutants for which criteria reflect only the two specified aquatic exposure routes, adjustments in water concentration values may be made. The Agency intends to publish guidance which will permit the States to identify significantly different exposure patterns for their populations. If warranted by the demonstration of significantly different exposure patterns, this will become an element of a process to adapt/modify human health-based criteria to local conditions, somewhat analogous to the aquatic life criteria modification process discussed previously. It is anticipated that States at their discretion will be able to set appropriate human health criteria based on this process.

The pharmacokinetics section reviews data on absorption, distribution, metabolism, and excretion to assess the biochemical fate of the compounds in the human and animal system. The toxic effects section reviews data on acute, subacute, and chronic toxicity, synergistic and antagonistic effects, and specific information on mutagenicity, teratogenicity, and carcinogenicity. From this review, the toxic effect to be protected against is identified taking into account the quality, quantity, and weight of evidence characteristic of the data. The criterion formulation section reviews the highlights of the text and specifies a rationale for criterion development and the mathematical derivation of the criterion number.

Within the limitations of time and resources, current published information of significance was incorporated into the human health assessments. Review articles and reports were used for data evaluation and synthesis. Scientific judgment was exercised in reviewing and evaluating the data in each criteria document and in identifying the adverse effects for which protective criteria were published.

Specific health-based criteria are developed only if a weight of evidence supports the occurrence of the toxic effect and if dose/response data exist from which criteria can be estimated.

Criteria for suspect or proven carcinogens are presented as concentrations in water associated with a range of incremental cancer risks to man. Criteria for non-carcinogens represent levels at which exposure to a single chemical is not anticipated to produce adverse effects in man. In a few cases, organoleptic (taste and odor) data form the basis for the criterion. While this type of criterion does not represent a value which directly affects human health, it is presented as an estimate of the level of a pollutant that will not produce unpleasant taste or odor either directly from water consumption or indirectly by consumption of aquatic organisms found in ambient waters. A criterion developed in this manner is judged to be as useful as other types of criteria in protecting designated water uses. In addition, where data are available, toxicity-based criteria are also presented for pollutants with derived organoleptic criteria. The choice of criteria used in water quality standards for these pollutants will depend upon the designated use to be protected. In the case of a multiple use water body, the criterion protecting the most sensitive use will be applied. Finally, for several pollutants no criteria are recommended due to a lack of information sufficient for quantitative criterion formulation.

Risk Extrapolation

Because methods do not now exist to establish the presence of a threshold for carcinogenic effects, EPA's policy is that there is no scientific basis for estimating "safe" levels for carcinogens. The criteria for carcinogens, therefore, state that the recommended concentration for maximum protection of human health is zero. In addition, the Agency has presented a range of concentrations corresponding to incremental cancer risks of 10^{-7} to 10^{-5} (one additional case of cancer in populations ranging from ten million to 100,000, respectively). Other concentrations representing different risk levels may be calculated by use of the Guidelines. The risk estimate range is presented for information purposes and does not represent an Agency judgment on an "acceptable" risk level.

Summary of the Human Health Guidelines

The health assessments and corresponding criteria published today were derived based on *Guidelines and Methodology Used in the Preparation of Health Effect Assessment Chapters of the Consent Decree Water Criteria Documents* (the Guidelines) developed by EPA's Office of Reserch and Development. The estimation of health risks associated with human exposure to environmental pollutants requires predicting the effect of low doses for up to a lifetime in duration. A combination of epidemiological and animal dose/response data is considered the preferred basis for quantitative criterion derivation. The complete Guidelines are presented as Appendix C. Major issues associated with these Guidelines and responses to public comments are presented as Appendix E.

No-effect (non-carcinogen) or specified risk (carcinogen) concentrations were estimated by extrapolation from animal toxicity or human epidemiology studies using the following basic exposure assumptions: a 70-kilogram male person (*Report of the Task Group on Reference Man*, International Commission for Radiation Protection, November 23, 1957) as the exposed individual; the average daily consumption of freshwater and estuarine fish and shellfish products equal to 6.5 grams/day; and the average ingestion of two liters/day of water (*Drinking Water and Health*, National Academy of Sciences, National Research Council, 1977). Criteria based on these assumptions are estimated to be protective of an adult male who experiences average exposure conditions.

Two basic methods were used to formulate health criteria, depending on whether the prominent adverse effect was cancer or other toxic manifestations. The following sections detail these methods.

Carcinogens

Extrapolation of cancer responses from high to low doses and subsequent risk estimation from animal data is performed using a linearized multi-stage model. This procedure is flexible enough to fit all monotonically-increasing dose response data, since it incorporates several adjustable parameters. The multi-stage model is a linear non-threshold model as was the "one-hit" model originally used in the proposed criteria documents. The linearized multi-stage model and its characteristics are described fully in Appendix C. The linear non-threshold concept has been endorsed by the four agencies in the Interagency Regulatory Liaison Group and is less likely to underestimate risk at the low doses typical of environmental exposure than other models that could be used. Because of the uncertainties associated with dose response, animal-to-human extrapolation and other unknown factors, because of the use of average exposure assumptions, and because of the serious public health consequences that could result if risk were underestimated, EPA believes that it is prudent to use conservative methods to estimate risk in the water quality criteria program. The linearized multistage model is more systematic and invokes fewer arbitrary assumptions than the "one-hit" procedure previously used.

It should be noted that extrapolation models provide estimates of risk since a varitey of assumptions are built into any model. Models using widely different assumptions may produce estimates ranging over several orders of magnitude. Since there is at present no way to demonstrate the scientific validity of any model, the use of risk extrapolation models is a subject of debate in the scientific community. However, risk extrapolation is generally recognized as the only tool available at this time for estimating the magnitude of health hazards associated with non-threshold toxicants and has been endorsed by numerous Federal agencies and scientific organizations, including EPA's Carcinogen Assessment Group, the National Academy of Sciences, and the Interagency Regulatory Liaison Group as a useful means of assessing the risks of exposure to various carcinogenic pollutants.

Non-Carcinogens

Health criteria based on toxic effects of pollutants other than carcinogenicity are estimates of concentrations which are not expected to produce adverse effects in humans. They are based upon Acceptable Daily Intake (ADI) levels and are generally derived using no-observed-adverse-effect-level (NOAEL) data from animal studies although human data are used wherever available. The ADI is calculated using safety factors to account for uncertainties inherent in extrapolation from animal to man. In accordance with the National Research Council recommendations *(Drinking Water and Health*, National Academy of Sciences, National Research Council, 1977), safety factors of 10, 100, or 1,000 are used depending on the quality and quantity of data. In some instances extrapolations are made from inhalation studies or limits to approximate a human response from ingestion using the Stokinger-Woodward model (Journal of American Water Works Association, 1958). Calculations of criteria from ADIs are made using the standard exposure assumptions (2 liters of water, 6.5 grams of edible aquatic products, and an average body weight of 70 kg).

Dated: October 24, 1980.

Douglas M. Costle,
Administrator.

Appendix A—Summary of Water Quality Criteria

Acenaphthene

Freshwater Aquatic Life

The available data for acenaphthene indicate that acute toxicity to freshwater aquatic life occurs at concentrations as low as 1,700 µg/l and would occur at lower concentrations among species that are more sensitive than those tested. No data are available concerning the chronic toxicity of acenaphthene to sensitive freshwater aquatic animals but toxicity to freshwater algae occur at concentrations as low as 520 µg/l.

Saltwater Aquatic Life

The available data for acenaphthene indicate that acute and chronic toxicity to saltwater aquatic life occur at concentrations as low as 970 and 710 µg/l, respectively, and would occur at lower concentrations among species that are more sensitive than those tested. Toxicity to algae occurs at concentrations as low as 500 µg/l.

Human Health

Sufficient data is not available for acenaphthene to derive a level which would protect against the potential toxicity of this compound. Using available organoleptic data, for controlling undesirable taste and odor quality of ambient water, the estimated level is 20 µg/l. It should be recognized that organoleptic data as a basis for establishing a water quality criteria have limitations and have no demonstrated relationship to potential adverse human health effects.

Acrolein

Freshwater Aquatic Life

The available data for acrolein indicate that acute and chronic toxicity to freshwater aquatic life occurs at concentrations as low as 68 and 21 µg/l, respectively, and would occur at lower concentrations among species that are more sensitive than those tested.

Saltwater Aquatic Life

The available data for acrolein indicate that acute toxicity to saltwater aquatic life occurs at concentrations as low as 55 µg/l and would occur at lower concentrations among species that are more sensitive than those tested. No data are available concerning the chronic toxicity of acrolein to sensitive saltwater aquatic life.

Human Health

For the protection of human health from the toxic properties of acrolein ingested through water and contaminated aquatic organisms, the ambient water criterion is determined to be 320 µg/l.

For the protection of human health from the toxic properties of acrolein ingested through contaminated aquatic organisms alone, the ambient water criterion is determined to be 780 µg/l.

Acrylonitrile

Freshwater Aquatic Life

The available data for acrylonitrile indicate that acute toxicity to freshwater aquatic life occurs at concentrations as low as 7,550 µg/l and would occur at lower concentrations among species that are more sensitive than those tested. No definitive data are available concerning the chronic toxicity of acrylonitrile to sensitive freshwater aquatic life but mortality occurs at concentrations as low as 2,600 µg/l with a fish species exposed for 30 days.

Saltwater Aquatic Life

Only one saltwater species has been tested with acrylonitrile and no statement can be made concerning acute or chronic toxicity.

Human Health

For the maximum protection of human health from the potential carcinogenic effects due to exposure of acrylonitrile through ingestion of contaminated water and contaminated aquatic organisms, the ambient water concentration should be zero based on the non-threshold assumption for this chemical. However, zero level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk over the lifetime are estimated at 10^{-5}, 10^{-6}, and 10^{-7}. The corresponding criteria are .58 µg/l, .058 µg/l and .006 µg/l, respectively. If the above estimates are made for consumption of aquatic organisms only, excluding consumption of water, the levels are 6.5 µg/l, .65 µg/l, and .065 µg/l, respectively. Other concentrations representing different risk levels may be calculated by use of the Guidelines. The risk estimate range is presented for information purposes and does not represent an Agency judgment on an "acceptable" risk level.

Aldrin-Dieldrin

Dieldrin

Freshwater Aquatic Life

For dieldrin the criterion to protect fresh water aquatic life as derived using the Guidelines is 0.0019 µg/l as a 24-hour average and the concentration should not exceed 2.5 µg/l at any time.

Saltwater Aquatic Life

For dieldrin the criterion to protect saltwater aquatic life as derived using the Guidelines is 0.0019 µg/l as a 24-hour average and the concentration should not exceed 0.71 µg/l at any time.

Human Health

For the maximum protection of human health from the potential carcinogenic effects due to exposure of dieldrin through ingestion of contaminated water and contaminated aquatic organisms, the ambient water concentration should be zero based on the non-threshold assumption for this chemical. However, zero level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk over the lifetime are estimated at 10^{-5}, 10^{-6}, and 10^{-7}. The corresponding criteria are .71 ng/l, .071 ng/l, and .0071 ng/l, respectively. If the above estimates are made for consumption of aquatic organisms only, excluding consumption of water, the levels are .76 ng/l, .076 ng/l, and .0076 ng/l respectively. Other concentrations representing different risk levels may be calculated by use of the Guidelines. The risk estimate range is presented for information purposes and does not represent an Agency judgment on an "acceptable" risk level.

Aldrin

Freshwater Aquatic Life

For freshwater aquatic life the concentration of aldrin should not exceed 3.0 µg/l at any time. No data are available concerning the chronic toxicity of aldrin to sensitive freshwater aquatic life.

Saltwater Aquatic Life

For saltwater aquatic life the concentration of aldrin should not exceed 1.3 µg/l at any time. No data are available concerning the chronic toxicity of aldrin to sensitive saltwater aquatic life.

Human Health

For the maximum protection of human health from the potential carcinogenic effects due to exposure of aldrin through ingestion of contaminated water and contaminated aquatic organisms, the ambient water concentration should be zero based on the non-threshold assumption for this chemical. However, zero level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk over the lifetime are estimated at 10^{-5}, 10^{-6}, and 10^{-7}. The corresponding criteria are .74 ng/1, .074 ng/1, and .0074 ng/1, respectively. If the above estimates are made for consumption of aquatic organisms only, excluding consumption of water, the levels are .79 ng/1, .079 ng/1, and .0079 ng/1, respectively. Other concentrations respresenting different risk levels may be calculated by use of the Guidelines. The risk estimate range is presented for information purposes and does not represent an Agency judgment on an "acceptable" risk level.

Antimony

Freshwater Aquatic Life

The available data for antimony indicate that acute and chronic toxicity to freshwater aquatic life occur at concentrations as low as 9,000 and 1,600 µg/l, respectively, and would occur at lower concentrations among species that are more sensitive than those tested. Toxicity to algae occurs at concentrations as low as 610 µg/l.

Saltwater Aquatic Life

No saltwater organisms have been adequately tested with antimony, and no statement can be made concerning acute or chronic toxicity.

Human Health

For the protection of human health from the toxic properties of antimony ingested through water and contaminated aquatic organisms, the ambient water criterion is determined to be 146 µg/l.

For the protection of human health from the toxic properties of antimony ingested through contaminated aquatic organisms alone, the ambient water criterion is determined to be 45,000 µg/l.

Arsenic

Freshwater Aquatic Life

For freshwater aquatic life the concentration of total recoverable trivalent inorganic arsenic should not exceed 440 µg/l at any time. Short-term effects on embryos and larvae of aquatic vertebrate species have been shown to occur at concentrations as low as 40 µg/l.

Saltwater Aquatic Life

The available data for total recoverable trivalent inorganic arsenic indicate that acute toxicity to saltwater aquatic life occurs at concentrations as low as 508 µg/l and would occur at lower concentrations among species that are more sensitive than those tested. No data are available concerning the chronic toxicity of trivalent inorganic arsenic to sensitive saltwater aquatic life.

Human Health

For the maximum protection of human health from the potential carcinogenic effects due to exposure of arsenic through ingestion of contaminated water and contaminated aquatic organisms, the ambient water concentration should be zero based on the non-threshold assumption for this chemical. However, zero level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk over the lifetime are estimated at 10^{-5}, 10^{-6}, and 10^{-7}. The corresponding criteria are 22 ng/l, 2.2 ng/l, and .22 ng/l, respectively. If the above estimates are made for consumption of aquatic organisms only, excluding consumption of water, the levels are 175 ng/l, 17.5 ng/l, and 1.75 ng/l, respectively. Other concentrations representing different risk levels may be calculated by use of the Guidelines. The risk estimate range is presented for information purposes and does not represent an Agency judgment on an "acceptable" risk level.

Asbestos

Freshwater Aquatic Life

No freshwater organisms have been tested with any asbestiform mineral and no statement can be made concerning acute or chronic toxicity.

Saltwater Aquatic Life

No saltwater organisms have been tested with any asbestiform mineral and no statement can be made concerning acute or chronic toxicity.

Human Health

For the maximum protection of human health from the potential carcinogenic effects due to exposure of asbestos through ingestion of contaminated water and contaminated aquatic organisms, the ambient water concentration should be zero based on the non-threshold assumption for this chemical. However, zero level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk over the lifetime are estimated at 10^{-5}, 10^{-6}, and 10^{-7}. The corresponding criteria are 300,000 fibers/1,30,000 fibers/1, and 3,000 fibers/1, respectively. Other concentrations representing different risk levels may be calculated by use of the Guidelines. The risk estimate range is presented for information purposes and does not represent an Agency judgment on an "acceptable" risk level.

Benzene

Freshwater Aquatic Life

The available data for benzene indicate that acute toxicity to freshwater aquatic life occurs at concentrations as low as 5,300 µg/l and would occur at lower concentrations among species that are more sensitive than those tested. No data are available concerning the chronic toxicity of benzene to sensitive freshwater aquatic life.

Saltwater Aquatic Life

The available data for benzene indicate that acute toxicity to saltwater aquatic life occurs at concentrations as low as 5,100 µg/l and would occur at lower concentrations among species that are more sensitive then those tested. No definitive data are available concerning the chronic toxicity of benzene to sensitive saltwater aquatic life, but adverse effects occur at concentrations as low as 700 µg/l with a fish species exposed for 168 days.

Human Health

For the maximum protection of human health from the potential carcinogenic effects due to exposure of benzene through ingestion of contaminated water and contaminated aquatic organisms, the ambient water concentration should be zero based on the non-threshold assumption for this chemical. However, zero level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk over the lifetime are estimated at 10^{-5}, 10^{-6}, and 10^{-7}. The corresponding criteria are 6.6 µg/l, .66 µg/l, and .066 µg/l, respectively. If the above estimates are made for consumption of aquatic organisms only, excluding consumption of water, the levels are 400 µg/l, 40.0 µg/l, and 4.0 µg/l, respectively. Other concentrations representing different risk levels may be calculated by use of the Guidelines. The risk estimate range is presented for information purposes and does not represent an Agency judgment on an "acceptable" risk level.

Benzidine

Freshwater Aquatic Life

The available data for benzidine indicate that acute toxicity to freshwater aquatic life occurs at concentrations as low as 2,500 µg/l and would occur at lower concentrations among species that are more sensitive than those tested. No data are available concerning the chronic toxicity of benzidine to sensitive freshwater aquatic life.

Saltwater Aquatic Life

No saltwater organisms have been tested with benzidine and no statement can be made concerning acute and chronic toxicity.

Human Health

For the maximum protection of human health from the potential carcinogenic effects due to exposure of benzidine through ingestion of contaminated water and contaminated aquatic organisms, the ambient water concentration should be zero based on the non-threshold assumption for this chemical. However, zero level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk over the lifetime are estimated at 10^{-5}, 10^{-6}, and 10^{-7}. The corresponding criteria are 1.2 ng/1, .12 ng/1, and .01 ng/1, respectively. If the above estimates are made for consumption of aquatic organisms only, excluding consumption of water, the levels are 5.3 ng/1, .53 ng/1, and .05 ng/1, respectively. Other concentrations representing different risk levels may be calculated by use of the Guidelines. The risk estimate range is presented for information purposes and does not represent an Agency judgment on an "acceptable" risk level.

Beryllium

Freshwater Aquatic Life

The available data for beryllium indicate that acute and chronic toxicity to freshwater aquatic life occurs at concentrations as low as 130 and 5.3 µg/l, respectively, and would occur at lower concentrations among species that are more sensitive than those tested. Hardness has a substantial effect on acute toxicity.

Salt water Aquatic Life

The limited saltwater data base available for beryllium does not permit any statement concerning acute or chronic toxicity.

Human Health

For the maximum protection of human health from the potential carcinogenic effects due to exposure of beryllium through ingestion of contaminated water and contaminated aquatic organisms, the ambient water concentration should be zero based on the non-threshold assumption for this chemical. However, zero level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk over the lifetime are estimated at 10^{-5}, 10^{-6}, and 10^{-7}. The corresponding criteria are 37 ng/l, 3.7 ng/l, and .37 ng/l, respectively. If the above estimates are made for consumption of aquatic organisms only, excluding consumption of water, the levels are 641 ng/l, 64.1 ng/l, and 6.41 ng/l, respectively. Other concentrations representing different risk levels may be calculated by use of the Guidelines. The risk estimate range is presented for information purposes and does not represent an Agency judgment on an "acceptable" risk level.

Cadmium

Freshwater Aquatic Life

For total recoverable cadmium the criterion (in µg/l) to protect freshwater aquatic life as derived using the Guidelines is the numerical value given by $e^{(1.05[\ln(\text{hardness})]-8.53)}$ as a 24-hour average and the concentration (in μg/l) should not exceed the numerical value given by $e^{(1.05[\ln(\text{hardness})]-3.73)}$ at any time. For example, a hardnesses of 50, 100, and 200 mg/l as $CaCO_3$ the criteria are 0.012, 0.025, and 0.051 μg/l, respectively, and the concentration of total recoverable cadmium should not exceed 1.5, 3.0 and 6.3 μg/l, respectively, at any time.

Saltwater Aquatic Life

For total recoverable cadmium the criterion to protect saltwater aquatic life as derived using the Guidelines is 4.5 μg/l as a 24-hour average and the concentration should not exceed 59 μg/l at any time.

Human Health

The ambient water quality criterion for cadmium is recommended to be identical to the existing drinking water standard which is 10 μg/l. Analysis of the toxic effects data resulted in a calculated level which is protective of human health against the ingestion of contaminated water and contaminated aquatic organisms. The calculated value is comparable to the present standard. For this reason a selective criterion based on exposure solely from consumption of 6.5 grams of aquatic organisms was not derived.

Carbon Tetrachloride

Freshwater Aquatic Life

The available data for carbon tetrachloride indicate that acute toxicity to freshwater aquatic life occurs at concentrations as low as 35,200 μg/l and would occur at lower concentrations among species that are more sensitive than those tested. No data are available concerning the chronic toxicity of carbon tetrachloride to sensitive freshwater aquatic life.

Saltwater Aquatic Life

The available data for carbon tetrachloride indicate that acute toxicity to saltwater aquatic life occurs at concentrations as low as 50,000 μg/l and would occur at lower concentrations among species that are more sensitive that those tested. No data are available concerning the chronic toxicity of carbon tetrachloride to sensitive saltwater aquatic life.

Human Health

For the maximum protection of human health from the potential carcinogenic effects due to exposure of carbon tetrachloride through ingestion of contaminated water and contaminated aquatic organisms the ambient water concentration should be zero based on the non-threshold assumption for this chemical. However, zero level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk over the lifetime are estimated at 10^{-5}, 10^{-6}, and 10^{-7}. The corresponding criteria are 4.0μg/l, .40 μg/l, and .04 μg/l, respectively. If the above estimates are made for consumption of aquatic organisms only, excluding consumption of water, the levels are 69.4 μg/l, 6.94 μg/l, and .69 μg/l, respectively. Other concentrations representing different risk levels may be calculated by use of the Guidelines. The risk estimate range is presented for information purposes and does not represent an Agency judgment on an "acceptable" risk level.

Chlordane

Freshwater Aquatic Life

For chlordane the criterion to protect freshwater aquatic life as derived using the Guidelines is 0.0043 μg/l as a 24-hour average and the concentration should not exceed 2.4 μg/l at any time.

Saltwater Aquatic Life

For chlordane the criterion to protect saltwater aquatic life as derived using the Guidelines is 0.0040 μg/l as a 24-hour average and the concentration should not exceed 0.09 μg/l at any time.

Human Health

For the maximum protection of human health from the potential carcinogenic effects due to exposure of chlordane through ingestion of contaminated water and contaminated aquatic organisms, the ambient water concentration should be zero based on the non-threshold assumption for this chemical. However, zero level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk over the lifetime are estimated at 10^{-5}, 10^{-6}, and 10^{-7}. The corresponding criteria are 4.6 ng/l, .46 ng/l, and .046 ng/l, respectively. If the above estimates are made for consumption of aquatic organisms only, excluding consumption of water, the levels are 4.8 ng/l, .48 ng/l, and .048 ng/l, respectively. Other concentrations representing different risk levels may be calculated by use of the Guidelines. The risk estimate range is presented for information purposes and does not represent an Agency judgment on an "acceptable" risk level.

Chlorinated Benzenes

Freshwater Aquatic Life

The available data for chlorinated benzenes indicate that acute toxicity to freshwater aquatic life occurs at concentrations as low as 250 μg/l and would occur at lower concentrations among species that are more sensitive than those tested. No data are available concerning the chronic toxicity of the more toxic of the chlorinated benzenes to sensitive freshwater aquatic life but toxicity occurs at concentrations as low as 50 μg/l for a fish species exposed for 7.5 days.

Saltwater Aquatic Life

The available data for chlorinated benzenes indicate that acute and chronic toxicity to saltwater aquatic life occur at concentrations as low as 160 and 129 μg/l, respectively, and would occur at lower concentrations among species that are more sensitive than those tested.

Human Health

For the maximum protection of human health from the potential carcinogenic effects due to expcsure of hexachlorobenzene through ingestion of contaminated water and contaminated aquatic organisms, the ambient water concentration should be zero based on the non-threshold assumption for this chemical. However, zero level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk over the lifetime are estimated at 10^{-5}, 10^{-6}, and 10^{-7}. The corresponding recommended criteria are 7.2 ng/l, .72 ng/l, and .072 ng/l, respectively. If the above estimates are made for consumption of aquatic organisms only, excluding consumption of water, the levels are 7.4 ng/l, .74 ng/l, and .074 ng/l, respectively.

For the protection of human health from the toxic properties of 1,2,4,5-tetrachlorobenzene ingested through water and contaminated aquatic organisms, the ambient water criterion is determined to be 38 μg/l.

For the protection of human health from the toxic properties of 1,2,4,5-tetrachlorobenzene ingested through contaminated aquatic organisms alone, the ambient water criterion is determined to be 48 μg/l.

For the protection of human health from the toxic properties of pentachlorobenzene ingested through water and contaminated aquatic organisms, the ambient water criterion is determined to be 74 μg/l.

For the protection of human health from the toxic properties of pentachlorobenzene ingested through contaminated aquatic organisms alone, the ambient water criterion is determined to be 85 μg/l.

Using the present guidelines, a satisfactory criterion cannot be derived at this time due to the insufficiency in the available data for trichlorobenzene.

For comparison purposes, two approaches were used to derive criterion levels for monochlorobenzene. Based on available toxicity data, for the protection of public health, the derived level is 488 µg/l. Using available organoleptic data, for controlling undesirable taste and odor quality of ambient water, the estimated level is 20 µg/l. It should be recognized that organoleptic data as a basis for establishing a water quality criteria have limitations and have no demonstrated relationship to potential adverse human health effects.

Chlorinated Ethanes

Freshwater Aquatic Life

The available freshwater data for chlorinated ethanes indicate that toxicity increases greatly with increasing chlorination, and that acute toxicity occurs at concentrations as low as 118,000 µg/l for 1,2-dichloroethane, 18,000 µg/l for two trichloroethanes, 9,320 µg/l for two tetrachloroethanes, 7,240 µg/l for pentachloroethane, and 980 µg/l for hexachloroethane. Chronic toxicity occurs at concentrations as low as 20,000 µg/l for 1,2-dichloroethane, 9,400 µg/l for 1,1,2-trichloroethane, 2,400 µg/l for 1,1,2,2,-tetrachloroethane, 1,100 µg/l for pentachloroethane, and 540 µg/l for hexachloroethane. Acute and chronic toxicity would occur at lower concentrations among species that are more sensitive than those tested.

Saltwater Aquatic Life

The available saltwater data for chlorinated ethanes indicate that toxicity increases greatly with increasing chlorination and that acute toxicity to fish and invertebrate species occurs at concentrations as low as 113,000 µg/l for 1,2-dichloroethane, 31,200 µg/l for 1,1,1-trichloroethane, 9,020 µg/l for 1,1,2,2-tetrachloroethane, 390 µg/l for pentachloroethane, and 940 µg/l for hexachloroethane. Chronic toxicity occurs at concentrations as low as 281 µg/l for pentachloroethane. Acute and chronic toxicity would occur at lower concentrations among species that are more sensitive than those tested.

Human Health

For the maximum protection of human health from the potential carcinogenic effects due to exposure of 1,2-dichloroethane through ingestion of contaminated water and contaminated aquatic organisms, the ambient water concentration should be zero based on the non-threshold assumption for this chemical. However, zero level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk over the lifetime are estimated at 10^{-5}, 10^{-6}, and 10^{-7}. The corresponding criteria are 9.4 µg/l, .94 µg/l, and .094 µg/l, respectively. If the above estimates are made for consumption of aquatic organisms only, excluding consumption of water, the levels are 2,430 µg/l, 243 µg/l, and 24.3 µg/l respectively. Other concentrations representing different risk levels may be calculated by use of the Guidelines. The risk estimate range is presented for information purposes and does not represent an Agency judgment on an "acceptable" risk level.

For the protection of human health from the toxic properties of 1,1,1-trichloroethane ingested through water and contaminated aquatic organism, the ambient water criterion is determined to be 18.4 mg/l.

For the protection of human health from the toxic properties of 1,1,1,-trichloroethane ingested through contaminated aquatic organisms alone, the ambient water criterion is determined to be 1.03 g/l.

For the maximum protection of human health from the potential carcinogenic effects due to exposure of 1,1,2-trichloroethane through ingestion of contaminated water and contaminated aquatic organisms, the ambient water concentration should be zero based on the non-threshold assumption for this chemical. However, zero level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk over the lifetime are estimated at 10^{-5}, 10^{-6}, and 10^{-7}. The corresponding criteria are 6.0 µg/l, .6 µg/l, and .06 µg/l, respectively. If the above estimates are made for consumption of aquatic organisms only, excluding consumption of water, the levels are 418 µg/l, 41.8 µg/l, and 4.18 µg/l respectively. Other concentrations representing different risk levels may be calculated by use of the Guidelines. The risk estimate range is presented for information purposes and does not represent an Agency judgment on an "acceptable" risk level.

For the maximum protection of human health from the potential carcinogenic effects due to exposure of 1,1,2,2-tetrachloroethane through ingestion of contaminated water and contaminated aquatic organisms, the ambient water concentration should be zero based on the non-threshold assumption for this chemical. However, zero level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk over the lifetime are estimated at 10^{-5}, 10^{-6}, and 10^{-7}. The corresponding criteria are 1.7 µg/l, .17 µg/l, and .017 µg/l, respectively. If the above estimates are made for consumption of aquatic organisms only, excluding consumption of water, the levels are 107 µg/l, 10.7 µg/l, and 1.07 µg/l, respectively. Other concentrations representing different risk levels may be calculated by use of the Guidelines. The risk estimate range is presented for information purposes and does not represent an Agency judgment on an "acceptable" risk level.

For the maximum protection of human health from the potential carcinogenic effects due to exposure of hexachloroethane through ingestion of contaminated water and contaminated aquatic organisms, the ambient water concentration should be zero based on the non-threshold assumption for this chemical. However, zero level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk over the lifetime are estimated at 10^{-5}, 10^{-6}, and 10^{-7}. The corresponding criteria are 19 µg/l, 1.9 µg/l, and .19 µg/l, respectively. If the above estimates are made for consumption of aquatic organisms only, excluding consumption of water, the levels are 87.4 µg/l, 8.74 µg/l, and .87 µg/l, respectively. Other concentrations representing different risk levels may be calculated by use of the Guidelines. The risk estimate range is presented for information purposes and does not represent an Agency judgment on an "acceptable" risk level.

Using the present guidelines, a satisfactory criterion cannot be derived at this time due to the insufficiency in the available data for monochloroethane.

Using the present guidelines, a satisfactory criterion cannot be derived at this time due to the insufficiency in the available data for 1,1,-dichloroethane.

Using the present guidelines, a satisfactory criterion cannot be derived at this time due to the insufficiency in the available data for 1,1,1,2,-tetrachloroethane.

Using the present guidelines, a satisfactory criterion cannot be derived at this time due to the insufficiency in the available data for pentachloroethane.

Chlorinated Naphthalenes

Freshwater Aquatic Life

The available data for chlorinated naphthalenes indicate that acute toxicity to freshwater aquatic life occurs at concentrations as low as 1,600 µg/l and would occur at lower concentrations among species that are more sensitive than those tested. No data are available concerning the chronic toxicity of chlorinated naphthalenes to sensitive freshwater aquatic life.

Saltwater Aquatic Life

The available data for chlorinated napthalenes indicate that acute toxicity to saltwater aquatic life occurs at concentrations as low as 7.5 µg/l and would occur at lower concentrations among species that are more sensitive than those tested. No data are available concerning the chronic toxicity of chlorinated naphthalenes to sensitive saltwater aquatic life.

Human Health

Using the present guidelines, a satisfactory criterion cannot be derived at this time due to the insufficiency in the available data for chlorinated napthalenes.

Chlorinated Phenols

Freshwater Aquatic Life

The available freshwater data for chlorinated phenols indicate that toxicity generally increases with increasing chlorination, and that acute toxicity occurs at concentrations as low as 30 µg/l for 4-chloro-3-methylphenol to greater than 500,000 µg/l for other compounds. Chronic toxicity occurs at concentrations as low as 970 µg/l for 2,4,6-trichlorophenol. Acute and chronic toxicity would occur at lower concentrations among species that are more sensitive than those tested.

Saltwater Aquatic Life

The available saltwater data for chlorinated phenols indicate that toxicity generally increases with increasing chlorination and that acute toxicity occurs at concentrations as low as 440 µg/l for 2,3,5,6-tetrachlorophenol and 29,700 µg/l for 4-chlorophenol. Acute toxicity would occur at lower concentrations among species that are more sensitive than those tested. No data are available concerning the chronic toxicity of chlorinated phenols to sensitive saltwater aquatic life.

Human Health

Sufficient data is not available for 3-monochlorophenol to derive a level which would protect against the potential toxicity of this compound. Using available organoleptic data, for controlling undesirable taste and odor quality of ambient water, the estimated level is 0.1 µg/l. It should be recognized that organoleptic data as a basis for establishing a water quality criteria have limitations and have no demonstrated relationship to potential adverse human health effects.

Sufficient data is not available for 4-monochlorophenol to derive a level which would protect against the potential toxicity of this compound. Using available organoleptic data, for controlling undesirable taste and odor quality of ambient water, the estimated level is 0.1 µg/l. It should be recognized that organoleptic data as a basis for establishing a water quality criteria have limitations and have no demonstrated relationship to potential adverse human health effects.

Sufficient data is not available for 2,3-dichlorophenol to derive a level which would protect against the potential toxicity of this compound. Using available organoleptic data, for controlling undesirable taste and odor quality of ambient water, the estimated level is .04 µg/l. It should be recognized that organoleptic data as a basis for establishing a water quality criteria have limitations and have no demonstrated relationship to potential adverse human health effects.

Sufficient data is not available for 2,5-dichlorophenol to derive a level which would protect against the potential toxicity of this compound. Using available organoleptic data, for controlling undesirable taste and odor quality of ambient water, the estimated level is .5 µg/l. It should be recognized that organoleptic data as a basis for establishing a water quality criteria have limitations and have no demonstrated relationship to potential adverse human health effects.

Sufficient data is not available for 2,6-dichlorophenol to derive a level which would protect against the potential toxicity of this compound. Using available organoleptic data, for controlling undesirable taste and odor quality of ambient water, the estimated level is .2 µg/l. It should be recognized that organoleptic data as a basis for establishing a water quality criteria have limitations and have no demonstrated relationship to potential adverse human health effects.

Sufficient data is not available for 3,4-dichlorophenol to derive a level which would protect against the potential toxicity of this compound. Using available organoleptic data, for controlling undesirable taste and odor quality of ambient water, the estimated level is .3 µg/l. It should be recognized that organoleptic data as a basis for establishing a water quality criteria have limitations and have no demonstrated relationship to potential adverse human health effects.

Sufficient data is not available for 2,3,4,6-tetrachlorophenol to derive a level which would protect against the potential toxicity of this compound. Using available organoleptic data, for controlling undesirable taste and odor quality of ambient water, the estimated level is 1 µg/l. It should be recognized that organoleptic data as a basis for establishing a water quality criteria have limitations and have no demonstrated relationship to potential adverse human health effects.

For comparison purposes, two approaches were used to derive criterion levels for 2,4,5-trichlorophenol. Based on available toxicity data, for the protection of public health, the derived level is 2.6 mg/l. Using available organoleptic data, for controlling undesirable taste and odor quality of ambient water, the estimated level is 1.0 µg/l. It should be recognized that organoleptic data as a basis for establishing a water quality criteria have limitations and have no demonstrated relationship to potential adverse human health effects.

For the maximum protection of human health from the potential carcinogenic effects due to exposure of 2,4,6-trichlorophenol through ingestion of contaminated water and contaminated aquatic organisms, the ambient water concentration should be zero based on the non-threshold assumption for this chemical. However, zero level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk over the lifetime are estimated at 10^{-5}, 10^{-6}, and 10^{-7}. The corresponding criteria are 12 µg/l, 1.2 µg/l, and .12 µg/l respectively. If the above estimates are made for consumption of aquatic organisms only, excluding consumption of water, the levels are 36 µg/l, 3.6 µg/l, and .36 µg/l, respectively. Other concentrations representing different risk levels may be calculated by use of the Guidelines. The risk estimate range is presented for information purposes and does not represent an Agency judgment on an "acceptable" risk level.

Using available organoleptic data, for controlling undesirable taste and odor quality of ambient water, the estimated level is 2 µg/l. It should be recognized that organoleptic data as a basis for establishing a water quality criterion have limitations and have no demonstrated relationship to potential adverse human health effects.

Sufficient data is not available for 2-methyl-4-chlorophenol to derive a level which would protect against any potential toxicity of this compound. Using available organoleptic data, for controlling undesirable taste and odor quality of ambient water, the estimated level is 1800 µg/l. It should be recognized that organoleptic data as a basis for establishing a water quality criterion have limitations and have no demonstrated relationship to potential adverse human health effects.

Sufficient data is not available for 3-methyl-4-chlorophenol to derive a level which would protect against the potential toxicity of this compound. Using available organoleptic data, for controlling undesirable taste and odor quality of ambient water, the estimated level is 3000 μg/l. It should be recognized that organoleptic data as a basis for establishing a water quality criterion have limitations and have no demonstrated relationship to potential adverse human health effects.

Sufficient data is not available for 3-methyl-6-chlorophenol to derive a level which would protect against the potential toxicity of this compound. Using available organoleptic data, for controlling undesirable taste and odor quality of ambient water, the estimated level is 20 μg/l. It should be recognized that organoleptic data as a basis for establishing a water quality criterion have limitations and have no demonstrated relationship to potential adverse human health effects.

Chloroalkyl Ethers

Freshwater Aquatic Life

The available data for chloroalkyl ethers indicate that acute toxicity to freshwater aquatic life occurs at concentrations as low as 238,000 μg/l and would occur at lower concentrations among species that are more sensitive than those tested. No definitive data are available concerning the chronic toxicity of chloroalkyl ethers to sensitive freshwater aquatic life.

Saltwater Aquatic Life

No saltwater organisms have been tested with any chloroalkyl ether and no statement can be made concerning acute and chronic toxicity.

Human Health

For the maximum protection of human health from the potential carcinogenic effects due to exposure of bis-(chloromethyl)-ether through ingestion of contaminated water and contaminated aquatic organisms, the ambient water concentration should be zero based on the non-threshold assumption for this chemical. However, zero level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk over the lifetime are estimated at 10^{-5}, 10^{-6}, and 10^{-7}. The corresponding criteria are .038 ng/l, .0038 ng/l, and .00038 ng/l, respectively. If the above estimates are made for consumption of aquatic organisms only, excluding consumption of water, the levels are 18.4 ng/l, 1.84 ng/l, and .184 ng/l, respectively. Other concentrations representing different risk levels may be calculated by use of the Guidelines. The risk estimate range is presented for information purposes and does not represent an Agency judgment on an "acceptable" risk level.

For the maximum protection of human health from the potential carcinogenic effects due to exposure of bis (2-chloroethyl) ether through ingestion of contaminated water and contaminated aquatic organisms, the ambient water concentration should be zero based on the non-threshold assumption for this chemical. However, zero level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk over the lifetime are estimated at 10^{-5}, 10^{-6}, and 10^{-7}. The corresponding criteria are .3 μg/l, .03 μg/l, and .003 μg/l, respectively. If the above estimates are made for consumption of aquatic organisms only, excluding consumption of water, the levels are 13.6 μg/l, 1.36 μg/l, and .136 μg/l, respectively. Other concentrations representing different risk levels may be calculated by use of the Guidelines. The risk estimate range is presented for information purposes and does not represent an Agency judgment on an "acceptable" risk level.

For the protection of human health from the toxic properties of bis (2-chloroisopropyl) ether ingested through water and contaminated aquatic organisms, the ambient water criterion is determined to be 34.7 μg/l.

For the protection of human health from the toxic properties of bis (2-chloroisopropyl) ether ingested through contaminated aquatic organisms alone, the ambient water criterion is determined to be 4.36 mg/l.

Chloroform

Freshwater Aquatic Life

The available data for choloroform indicate that acute toxicity to freshwater aquatic life occurs at concentrations as low as 28,900 μg/l, and would occur at lower concentrations among species that are more sensitive than the three tested species. Twenty-seven-day LC50 values indicate that chronic toxicity occurs at concentrations as low as 1,240 μg/l, and could occur at lower concentrations among species or other life stages that are more sensitive than the earliest life cycle stage of the rainbow trout.

Saltwater Aquatic Life

The data base for saltwater species is limited to one test and no statement can be made concerning acute or chronic toxicity.

Human Health

For the maximum protection of human health from the potential carcinogenic effects due to exposure of chloroform through ingestion of contaminated water and contaminated aquatic organisms, the ambient water concentration should be zero based on the non-threshold assumption for this chemical. However, zero level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk over the lifetime are estimated at 10^{-5}, 10^{-6}, and 10^{-7}. The corresponding criteria are 1.90 μg/l, .19 μg/l, and .019 μg/l, respectively. If the above estimates are made for consumption of aquatic organisms only, excluding consumption of water, the levels are 157 μg/l, 15.7 μg/l, and 1.57 μg/l, respectively. Other concentrations representing different risk levels may be calculated by use of the Guidelines. The risk estimate range is presented for information purposes and does not represent an Agency judgment on an "acceptable" risk level.

2-Chlorophenol

Freshwater Aquatic Life

The availabe data for 2-chlorophenol indicate that acute toxicity to freshwater aquatic life occurs at concentrations as low as 4,380 μg/l and would occur at lower concentrations among species that are more sensitive that those tested. No definitive data are available concerning the chronic toxicity of 2-chlorophenol to sensitive freshwater aquatic life but flavor impairment occurs in one species of fish at concentrations as low as 2,000 μg/l.

Saltwater Aquatic Life

No saltwater organisms have been tested with 2-chlorophenol and no statement can be made concerning acute and chronic toxicity.

Human Health

Sufficient data is not available for 2-chlorophenol to derive a level which would protect against the potential toxicity of this compound. Using available organoleptic data, for controlling undesirable taste and odor quality of ambient water, the estimated level is 0.1 μg/l. It should be recognized that organoleptic data as a basis for establishing a water quality criteria have limitations and have no demonstrated relationship to potential adverse human health effects.

Chromium

Freshwater Aquatic Life

For total recoverable hexavalent chromium the criterion to protect freshwater aquatic life as derived using the Guidelines is 0.29 μg/l as a 24-hour average and the concentration should not exceed 21 μg/l at any time.

For freshwater aquatic life the concentration (in μg/l) of total recoverable trivalent chromium should not exceed the numerical value given by "$e^{(1.08[\ln(\text{hardness})]+3.48)}$" at any time. For example, at hardnesses of 50, 100 and 200 mg/l as $CaCO_3$ the concentration of total recoverable trivalent chromium should not exceed 2,200, 4,700, and 9,900 μg/l, respectively, at any time. The available data indicate that chronic toxicity to freshwater aquatic life occurs at concentrations as low a 44 μg/l and would occur at lower concentrations among species that are more sensitive than those tested.

Saltwater Aquatic Life

For total recoverable hexavalent chromium the criterion to protect saltwater aquatic life as derived using the Guidelines is 18 μg/l as a 24-hour average and the concentration should not exceed 1,260 μg/l at any time.

For total recoverable trivalent chromium, the availabe data indicate that acute toxicity to saltwater aquatic life occurs at concentrations as low as 10,300 μg/l, and would occur at lower concentrations amoung species that are more sensitive than those tested. No data are available concerning the chronic toxicity of trivalent chromium to sensitive saltwater aquatic life.

Human Health

For the protection of human health from the toxic properties of Chromium III ingested through water and contaminated aquatic organisms, the ambient water criterion is determined to be 170 mg/l.

For the protection of human health from the toxic properties of Chromium III ingested through contaminated aquatic organisms alone, the ambient water criterion is determined to be 3433 mg/l.

The ambient water quality criterion for total Chromium VI is recommended to be identical to the existing drinking water standard which is 50 μg/l. Analysis of the toxic effects data resulted in a calculated level which is protective of human health against the ingestion of contaminated water and contaminated aquatic organisms. The calculated value is comparable to the present standard. For this reason a selective criterion based on exposure solely from consumption of 6.5 grams of aquatic organisms was not derived.

Copper

Freshwater Aquatic Life

For total recoverable copper the criterion to protect freshwater aquatic life as derived using the Guidelines is 5.6 μg/l as a 24-hour average and the concentration (in μg/l) should not exceed the numerical value given by $e^{(0.94[\ln(\text{hardness})]-1.23)}$ at any time. For example, at hardnesses of 50, 100, and 200 mg/l $CaCO_3$ the concentration of total recoverable copper should not exceed 12, 22, and 43 μg/l at any time.

Saltwater Aquatic Life

For total recoverable copper the criterion to protect saltwater aquatic life as derived using the Guidelines is 4.0 μg/l as a 24-hour average and the concentration should not exceed 23 μg/l at any time.

Human Health

Sufficient data is not available for copper to derive a level which would protect against the potential toxicity of this compound. Using available organoleptic data, for controlling undesirable taste and odor quality of ambient water, the estimated level is 1 mg/l. It should be recognized that organoleptic data as a basis for establishing a water quality criteria have limitations and have no demonstrated relationship to potential adverse human health effects.

Cyanide

Freshwater Aquatic Life

For free cyanide (sum of cyanide present as HCN and CN^-, expressed as CN) the criterion to protect freshwater aquatic life as derived using the Guidelines is 3.5 μg/l as a 24-hour average and the concentration should not exceed 52 μg/l at any time.

Saltwater Aquatic Life

The available data for free cyanide (sum of cyanide present as HCN and CN^-, expressed as CN) indicate that acute toxicity to saltwater aquatic life occurs at concentrations as low as 30 μg/l and would occur at lower concentrations among species that are more sensitive than those tested. If the acute-chronic ratio for saltwater organisms is similar to that for freshwater organisms, chronic toxicity would occur at concentrations as low as 2.0 μg/l for the tested species and at lower concentrations among species that are more sensitive than those tested.

Human Health

The ambient water quality criterion for cyanide is recommended to be identical to the existing drinking water standard which is 200 μg/l. Analysis of the toxic effects data resulted in a calculated level which is protective of human health against the ingestion of contaminated water and contaminated aquatic organisms. The calculated value is comparable to the present standard. For this reason a selective criterion based on exposure solely from consumption of 6.5 grams of aquatic organisms was not derived.

DDT and Metabolites

Freshwater Aquatic Life

DDT

For DDT and its metabolites the criterion to protect freshwater aquatic life as derived using the Guidelines is 0.0010 μg/l as a 24-hour average and the concentration should not exceed 1.1 μg/l at any time.

TDE

The available data for TDE indicate that acute toxicity to freshwater aquatic life occurs at concentrations as low as 0.6 μg/l and would occur at lower concentrations among species that are more sensitive than those tested. No data are available concerning the chronic toxicity of TDE to sensitive freshwater aquatic life.

DDE

The available data for DDE indicate that acute toxicity to freshwater aquatic life occurs at concentrations as low as 1,050 μg/l and would occur at lower concentrations among species that are more sensitive than those tested. No data are available concerning the chronic toxicity of DDE to sensitive freshwater aquatic life.

Saltwater Aquatic Life

DDT

For DDT and its metabolites the criterion to protect saltwater aquatic life as derived using the Guidelines is 0.0010 μg/l as a 24-hour average and the concentration should not exceed 0.13 μg/l at any time.

TDE

The available data for TDE indicate that acute toxicity to saltwater aquatic life occurs at concentrations as low as 3.6 μg/l and would occur at lower concentrations among species that are more sensitive than those tested. No data are available concerning the chronic toxicity of TDE to sensitive saltwater aquatic life.

DDE

The available data for DDE indicate that acute toxicity to saltwater aquatic life occurs at concentrations as low as 14 µg/l and would occur at lower concentrations among species that are more sensitive than those tested. No data are available concerning the chronic toxicity of DDE to sensitive saltwater aquatic life.

Human Health

For the maximum protection of human health from the potential carcinogenic effects due to exposure of DDT through ingestion of contaminated water and contaminated aquatic organisms, the ambient water concentration should be zero based on the non-threshold assumption for this chemical. However, zero level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk over the lifetime are estimated at 10^{-5}, 10^{-6}, and 10^{-7}. The corresponding criteria are .24 ng/l, .024 ng/l, and .0024 ng/l, respectively. If the above estimates are made for consumption of aquatic organisms only, excluding consumption of water, the levels are .24 ng/l, .024 ng/l, and .0024 ng/l, respectively. Other concentrations representing different risk levels may be calculated by use of the Guidelines. The risk estimate range is presented for information purposes and does not represent an Agency judgment of an "acceptable" risk level.

Dichlorobenzenes

Freshwater Aquatic Life

The available data for dichlorobenzenes indicate that acute and chronic toxicity to freshwater aquatic life occurs at concentrations as low as 1,120 and 763 µg/l, respectively, and would occur at lower concentrations among species that are more sensitive than those tested.

Saltwater Aquatic Life

The available data for dichlorobenzenes indicate that acute toxicity to saltwater aquatic life occurs at concentrations as low as 1,970 µg/l and would occur at lower concentrations among species that are more sensitive than those tested. No data are available concerning the chronic toxicity of dichlorobenzenes to sensitive saltwater aquatic life.

Human Health

For the protection of human health from the toxic properties of dichlorobenzenes (all isomers) ingested through water and contaminated aquatic organisms, the ambient water criterion is determined to be 400 µg/l.

For the protection of human health from the toxic properties of dichlorobenzenes (all isomers) ingested through contaminated aquatic organisms alone, the ambient water criterion is determined to be 2.6 mg/l.

Dichlorobenzidines

Freshwater Aquatic Life

The data base available for dichlorobenzidines and freshwater organisms is limited to one test on bioconcentration of 3,3'-dichlorobenzidine and no statement can be made concerning acute or chronic toxicity.

Saltwater Aquatic Life

No saltwater organisms have been tested with any dichlorobenzidine and no statement can be made concerning acute or chronic toxicity.

Human Health

For the maximum protection of human health from the potential carcinogenic effects due to exposure of dichlorobenzidine through ingestion of contaminated water and contaminated aquatic organisms, the ambient water concentration should be zero base on the non-threshold assumption for this chemical. However, zero level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk over the lifetime are estimated at 10^{-5}, 10^{-6}, and 10^{-7}. The corresponding criteria are .103 µg/l, .0103 µg/l, and .00103 µg/l, respectively. If the above estimates are made for consumption of aquatic organisms only, excluding consumption of water, the levels are .204 µg/l, .0204 µg/l, and .00204 µg/l, respectively. Other concentrations representing different risk levels may be calculated by use of the Guidelines. The risk estimate range is presented for information purposes and does not represent an Agency judgment on an "acceptable" risk level.

Dichloroethylenes

Freshwater Aquatic Life

The available data for dichloroethylenes indicate that acute toxicity to freshwater aquatic life occurs at concentrations as low as 11,600 µg/l and would occur at lower concentrations among species that are more sensitive than those tested. No definitive data are available concerning the chronic toxicity of dichlorethylenes to sensitive freshwater aquatic life.

Saltwater Aquatic Life

The available data for dichlorethylenes indicate that acute toxicity to saltwater aquatic life occurs at concentrations as low as 224,000 µg/l and would occur at lower concentrations among species that are more sensitive than those tested. No data are available concerning the chronic toxicity dichloroethylenes to sensitive saltwater aquatic life.

Human Health

For the maximum protection of human health from the potential carcinogenic effects due to exposure of 1,1-dichloroethylene through ingestion of contaminated water and contaminated aquatic organisms, the ambient water concentration should be zero based on the non-threshold assumption for this chemical. However, zero level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk over the lifetime are estimated at 10^{-5}, 10^{-6}, and 10^{-7}. The corresponding criteria are .33 µg/l, .033 µg/l, and .0033 µg/l, respectively. If the above estimates are made for consumption of aquatic organisms only, excluding consumption of water, the levels are 18.5 µg/l, 1.85 µg/l, and .185 µg/l, respectively. Other concentrations representing different risk levels may be calculated by use of the Guidelines. The risk estimate range is presented for information purposes and does not represent an Agency judgment on an "acceptable" risk level.

Using the present guidelines, a satisfactory criterion cannot be derived at this time due to the insufficency in the available data for 1,2-dichloroethylene.

2,4-Dichlorophenol

Freshwater Aquatic Life

The available data for 2,4-dichlorophenol indicate that acute and chronic toxicity to freshwater aquatic life occurs at concentrations as low as 2,020 and 365 µg/l, respectively, and would occur at lower concentrations among species that are more sensitive that those tested. Mortality to early life stages of one species of fish occurs at concentrations as low as 70 µg/l.

Saltwater Aquatic Life

Only one test has been conducted with saltwater organisms on 2,4-dichlorophenol and no statement can be made concerning acute or chronic toxicity.

Human Health

For comparison purposes, two approaches were used to derive criterion levels for 2,4-dichlorophenol.

Based on available toxicity data, for the protection of public health, the derived level is 3.09 mg/l. Using available organoleptic data, for controlling undesirable taste and odor quality of ambient water, the estimated level is 0.3 µg/l. It should be recognized that organoleptic data as a basis for establishing a water quality criteria have limitations and have no demonstrated relationship to potential adverse human health effects.

Dichloropropanes/Dichloropropenes

Freshwater Aquatic Life

The available data for dichloropropanes indicate that acute and chronic toxicity to freshwater aquatic life occurs at concentrations as low as 23,000 and 5,700 µg/l, respectively, and would occur at lower concentrations among species that are more sensitive than those tested.

The available data for dichloropropenes indicate that acute and chronic toxicity to freshwater aquatic life occurs at concentrations as low as 6,060 and 244 µg/l, respectively, and would occur at lower concentrations among species that are more sensitive than those tested.

Saltwater Aquatic Life

The available data for dichloropropanes indicate that acute and chronic toxicity to saltwater aquatic life occurs at concentrations as low as 10,300 and 3,040 µg/l, respectively, and would occur at lower concentrations among species that are more sensitive than those tested.

The available data for dichloropropenes indicate that acute toxicity to saltwater aquatic life occurs at concentrations as low a as 790 µg/l, and would occur at lower concentrations among species that are more sensitive than those tested. No data are available concerning the chronic toxicity of dichloropropenes to sensitive saltwater aquatic life.

Human Health

Using the present guidelines, a satisfactory criterion cannot be derived at this time due to the insufficiency in the available data for dichloropropanes.

For the protection of human health from the toxic properties of dichloropropenes ingested through water and contaminated aquatic organisms, the ambient water criterion is determined to be 87 µg/l.

For the protection of human health from the toxic properties of dichloropropenes ingested through contaminated aquatic organisms alone, the ambient water criterion is determined to be 14.1 mg/l.

2,4-Dimethylphenol

Freshwater Aquatic Life

The available data for 2,4-dimethylphenol indicate that acute toxicity to freshwater aquatic life occurs at concentrations as low as 2,120 µg/l and would occur at lower concentrations among species that are more sensitive than those tested. No data are available concerning the chronic toxicity of dimethylphenol to sensitive freshwater aquatic life.

Saltwater Aquatic Life

No saltwater organisms have been tested with 2,4-dimethylphenol and no statement can be made concerning acute and chronic toxicity.

Human Health

Sufficient data are not available for 2,4-dimethylphenol to derive a level which would protect against the potential toxicity of this compound. Using available organoleptic data, for controlling undersirable taste and odor quality of ambient water, the estimated level is 400 µg/l. It should be recognized that organoleptic data as a basis for establishing a water quality criteria have limitations and have no demonstrated relationship to potential adverse human health effects.

2,4-Dinitrotoluene

Freshwater Aquatic Life

The available data for 2,4-dinitrotoluene indicate that acute and chronic toxicity to freshwater aquatic life occurs at concentrations as low as 330 and 230 µg/l, respectively, and would occur at lower concentrations among species that are more sensitive than those tested.

Saltwater Aquatic Life

The available data for 2,4-dinitrotoluenes indicate that acute toxicity to saltwater aquatic life occurs at concentrations as low as 590 µg/l and would occur at lower concentrations among species that are more sensitive than those tested. No data are available concerning the chronic toxicity of 2,4-dinitrotoluenes to sensitive saltwater aquatic life but a decrease in algal cell numbers occurs at concentrations as low as 370 µg/l.

Human Health

For the maximum protection of human health from the potential carcinogenic effects due to exposure of 2,4-dinitrotoluene through ingestion of contaminated water and contaminated aquatic organisms, the ambient water concentration should be zero based on the non-threshold assumption for this chemical. However, zero level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk over the lifetime are estimated at 10^{-5}, 10^{-6}, and 10^{-7}. The corresponding criteria are 1.1 µg/l, 0.11 µg/l, and 0.011 µg/l, respectively. If the above estimates are made for consumption of aquatic organisms only, excluding consumption of water, the levels are 91 µg/l, 9.1 µg/l, and 0.91 µg/l, respectively. Other concentrations representing different risk levels may be calculated by use of the Guidelines. The risk estimate range is presented for information purposes and does not represent an Agency judgment on an "acceptable" risk level.

1,2-Diphenylhydrazine

Freshwater Aquatic Life

The available data for 1,2-diphenylhydrazine indicate that acute toxicity to freshwater aquatic life occurs at concentrations as low as 270 µg/l and would occur at lower concentrations among species that are more sensitive than those tested. No data are available concerning the chronic toxicity of 1,2-diphenylhydrazine to sensitive freshwater aquatic life.

Saltwater Aquatic Life

No saltwater organisms have been tested with 1,2-diphenylhydrazine and no statement can be made concerning acute and chronic toxicity.

Human Health

For the maximum protection of human health from the potential carcinogenic effects due to exposure of 1,2-diphenylhydrazine through ingestion of contaminated water and contaminated aquatic organisms, the ambient water concentration should be zero based on the non-threshold assumption for this chemical. However, zero level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk over the lifetime are estimated at 10^{-5}, 10^{-6}, and 10^{-7}. The corresponding criteria are 422 ng/l, 42 ng/l, and 4 ng/l, respectively. If the above estimates are made for consumption of aquatic organisms only, excluding consumption of water, the levels are 5.6 µg/l, 0.56 µg/l, and 0.056 µg/l, respectively. Other concentrations representing different risk levels may be calculated by use of the Guidelines. The risk estimate range is presented for information purposes and does not represent an Agency judgment on an "acceptable" risk level.

Endosulfan

Freshwater Aquatic Life

For endosulfan the criterion to protect freshwater aquatic life as derived using the Guidelines is 0.056 μg/l as a 24-hour average and the concentration should not exceed 0.22 μg/l at any time.

Saltwater Aquatic Life

For endosulfan the criterion to protect saltwater aquatic life as derived using the Guidelines is 0.0087 μg/l as a 24-hour average and the concentration should not exceed 0.034 μg/l at any time.

Human Health

For the protection of human health from the toxic properties of endosulfan ingested through water and contaminated aquatic organisms, the ambient water criterion is determined to be 74 μg/l.

For the protection of human health from the toxic properties of endosulfan ingested through contaminated aquatic organisms alone, the ambient water criterion is determined to be 159 μg/l.

Endrin

Freshwater Aquatic Life

For endrin the criterion to protect freshwater aquatic life as derived using the Guidelines is 0.0023 μg/l as a 24-hour average and the concentration should not exceed 0.18 μg/l at any time.

Saltwater Aquatic Life

For endrin the criterion to protect saltwater aquatic life as derived using the Guidelines is 0.0023 μg/l as a 24-hour average and the concentration should not exceed 0.037 μg/l at any time.

Human Health

The ambient water quality criterion for endrin is recommended to be identical to the existing drinking water standard which is 1 μg/l. Analysis of the toxic effects data resulted in a calculated level which is protective of human health against the ingestion of contaminated water and contaminated aquatic organisms. The calculated value is comparable to the present standard. For this reason a selective criterion based on exposure solely from consumption of 6.5 grams of aquatic organisms was not derived.

Ethylbenzene

Freshwater Aquatic Life

The available data for ethylbenzene indicate that acute toxicity to freshwater aquatic life occurs at concentrations as low as 32,000 μg/l and would occur at lower concentrations among species that are more sensitive than those tested. No definitive data are available concerning the chronic toxicity of ethylbenzene to sensitive freshwater aquatic life.

Saltwater Aquatic Life

The available data for ethylbenzene indicate that acute toxicity to saltwater aquatic life occurs at concentrations as low as 430 μg/l and would occur at lower concentrations among species that are more sensitive than those tested. No data are available concerning the chronic toxicity of ethylbenzene to sensitive saltwater aquatic life.

Human Health

For the protection of human health from the toxic properties of ethylbenzene ingested through water and contaminated aquatic organisms, the ambient water criterion is determined to be 1.4 mg/l.

For the protection of human health from the toxic properties of ethylbenzene ingested through contaminated aquatic organisms alone, the ambient water criterion is determined to be 3.28 mg/l.

Fluoranthene

Freshwater Aquatic Life

The available data for fluoranthene indicate that acute toxicity to freshwater aquatic life occurs at concentrations as low as 3980 μg/l and would occur at lower concentrations among species that are more sensitive than those tested. No data are available concerning the chronic toxicity of fluoranthene to sensitive freshwater aquatic life.

Saltwater Aquatic Life

The available data for fluoranthene indicate that acute and chronic toxicity to saltwater aquatic life occur at concentrations as low as 40 and 16 μg/l, respectively, and would occur at lower concentrations among species that are more sensitive than those tested.

Human Health

For the protection of human health from the toxic properties of fluoranthene ingested through water and contaminated aquatic organisms, the ambient water criterion is determined to be 42 μg/l.

For the protection of human health from the toxic properties of fluoranthene ingested through contaminated aquatic organisms alone, the ambient water criterion is determined to be 54 μg/l.

Haloethers

Freshwater Aquatic Life

The available data for haloethers indicate that acute and chronic toxicity to freshwater aquatic life occur at concentrations as low as 360 and 122 μg/l, respectively, and would occur at lower concentrations among species that are more sensitive than those tested.

Saltwater Aquatic Life

No saltwater organisms have been tested with any haloether and no statement can be made concerning acute or chronic toxicity.

Human Health

Using the present guidelines, a satisfactory criterion cannot be derived at this time due to the insufficiency in the available data for haloethers.

Halomethanes

Freshwater Aquatic Life

The available data for halomethanes indicate that acute toxicity to freshwater aquatic life occurs at concentrations as low as 11,000 μg/l and would occur at lower concentrations among species that are more sensitive than those tested. No data are available concerning the chronic toxicity of halomethanes to sensitive freshwater aquatic life.

Saltwater Aquatic Life

The available data for halomethanes indicate that acute and chronic toxicity to saltwater aquatic life occur at concentrations as low as 12,000 and 6,400 μg/l, respectively, and would occur at lower concentrations among species that are more sensitive than those tested. A decrease in algal cell numbers occurs at concentrations as low as 11,500 μg/l.

Human Health

For the maximum protection of human health from the potential carcinogenic effects due to exposure of chloromethane, bromomethane, dichloromethane, bromodichloromethane, tribromomethane, dichlorodifluoromethane, trichlorofluoromethane, or combinations of these chemicals through ingestion of contaminated water and contaminated aquatic organisms, the ambient water concentration should be zero based on the non-threshold assumption for this chemical. However, zero level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk, over the lifetimes are estimated at 10^{-5}, 10^{-6}, and 10^{-7}. The corresponding criteria are

1.9 μg/l, 0.19 μg/l, and 0.019 μg/l, respectively. If the above estimates are made for consumption of aquatic organisms only, excluding consumption of water, the levels are 157 μg/l, 15.7 μg/l, and 1.57 μg/l, respectively. Other concentrations representing different risk levels may be calculated by use of the Guidelines. The risk estimate range is presented for information purposes and does not represent an Agency judgment on an "acceptable" risk level.

Heptachlor

Freshwater Aquatic Life

For heptachlor the criterion to protect freshwater aquatic life as derived using the Guidelines is 0.0038 μg/l as a 24-hour average and the concentration should not exceed 0.52 μg/l at any time.

Saltwater Aquatic Life

For heptachlor the criterion to protect saltwater aquatic life as derived using the Guidelines is 0.0036 μg/l as a 24-hour average and the concentration should not exceed 0.053 μg/l at any time.

Human Health

For the maximum protection of human health from the potential carcinogenic effects due to exposure of heptachlor through ingestion of contaminated water and contaminated aquatic organisms, the ambient water concentration should be zero based on the non-threshold assumption for this chemical. However, zero level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk, over the lifetimes are estimated at 10^{-5}, 10^{-6}, and 10^{-7}. The corresponding criteria are 2.78 ng/l, .28 ng/l, and .028 ng/l, respectively. If the above estimates are made for consumption of aquatic organisms only, excluding consumption of water, the levels are 2.85 ng/l, .29 ng/l, and .029 ng/l, respectively. Other concentrations representing different risk levels may be calculated by use of the Guidelines. The risk estimate range is presented for information purposes and does not represent an Agency judgment on an "acceptable" risk level.

Hexachlorobutadiene

Freshwater Aquatic Life

The available data for hexachlorobutadiene indicate that acute and chronic toxicity to freshwater aquatic life occur at concentrations as low as 90 and 9.3 μg/l, respectively, and would occur at lower concentrations among species that are more sensitive than those tested.

Saltwater Aquatic Life

The available data for hexachlorobutadiene indicate that acute toxicity to saltwater aquatic life occurs at concentrations as low as 32 μg/l and would occur at lower concentrations among species that are more sensitive that those tested. No data are available concerning the chronic toxicity of hexachlorobutadiene to sensitive saltwater aquatic life

Human Health

For the maximum protection of human health from the potential carcinogenic effects due to exposure of hexachlorobutadiene through ingestion of contaminated water and contaminated aquatic organisms, the ambient water concentration should be zero based on the non-threshold assumption for this chemical. However, zero level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk, over the lifetimes are estimated at 10^{-5}, 10^{-6}, and 10^{-7}. The corresponding criteria are 4.47 μg/l, 0.45 μg/l, and 0.045 μg/l, respectively. If the above estimates are made for consumption of aquatic organisms only, excluding consumption of water, the levels are 500 μg/l, 50 μg/l, and 5 μg/l respectively. Other concentrations representing different risk levels may be calculated by use of the Guidelines. The risk estimate range is presented for information purposes and does not represent an Agency judgment on an "acceptable" risk level.

Hexachlorocyclohexane

Lindane

Freshwater Aquatic Life

For Lindane the criterion to protect freshwater aquatic life as derived using the Guidelines is 0.080 μg/l as a 24-hour average and the concentration should not exceed 2.0 μg/l at any time.

Saltwater Aquatic Life

For saltwater aquatic life the concentration of lindane should not exceed 0.16 μg/l at any time. No data are available concerning the chronic toxicity of lindane to sensitive saltwater aquatic life.

BHC

Freshwater Aquatic Life

The available date for a mixture of isomers of BHC indicate that acute toxicity to freshwater aquatic life occurs at concentrations as low as 100 μg/l and would occur at lower concentrations among species that are more sensitive than those tested. No data are available concerning the chronic toxicity of a mixture of isomers of BHC to sensitive freshwater aquatic life.

Saltwater Aquatic Life

The available date for a mixture of isomers of BHC indicate that acute toxicity to saltwater aquatic life occurs at concentrations as low as 0.34 μg/l and would occur at lower concentrations among species that are more sensitive than those tested. No data are available concerning the chronic toxicity of a mixture of isomers of BHC to sensitive saltwater aquatic life.

Human Health

For the maximum protection of human health from the potential carcinogenic effects due to exposure of alpha-HCH through ingestion of contaminated water and contaminated aquatic organisms, the ambient water concentration should be zero based on the non-threshold assumption for this chemical. However, zero level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk, over the lifetimes are estimated at 10^{-5}, 10^{-6}, and 10^{-7}. The corresponding criteria are 92 ng/l, 9.2 ng/l, and .92 ng/l, respectively. If the above estimates are made for consumption of aquatic organisms only, excluding consumption of water, the levels are 310 ng/l, 31.0 ng/l, and 3.1 ng/l respectively. Other concentrations representing different risk levels may be calculated by use of the Guidelines. The risk estimate range is presented for information purposes and does not represent an Agency judgment on an "acceptable" risk level.

For the maximum protection of human health from the potential carcinogenic effects due to exposure of beta-HCH through ingestion of contaminated water and contaminated aquatic organisms, the ambient water concentration should be zero based on the non-threshold assumption for this chemical. However, zero level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk, over the lifetimes are estimated at 10^{-5}, 10^{-6}, and 10^{-7}. The corresponding criteria are 163 ng/l, 16.3 ng/l, and 1.63 ng/l, respectively. If the above estimates are made for consumption of aquatic organisms only, excluding consumption of water, the levels are 547 ng/l, 54.7 ng/l, and 5.47 ng/l, respectively. Other concentrations representing different risk levels may be calculated by use of the Guidelines. The risk estimate range is presented for information purposes and does not represent an Agency judgment on an "acceptable" risk level.

For the maximum protection of human health from the potential carcinogenic effects due to exposure of tech-HCH through ingestion of contaminated water and contaminated aquatic organisms, the ambient water concentration should be zero based on the non-threshold assumption for this chemical. However, zero level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk, over the lifetimes are estimated at 10^{-5}, 10^{-6}, and 10^{-7}. The corresponding criteria are 123 ng/l, 12.3 ng/l, and 1.23 ng/l, respectively. If the above estimates are made for consumption of aquatic organisms only, excluding consumption of water, the levels are 414 ng/l, 41.4 ng/l, and 4.14 ng/l, respectively. Other concentrations representing different risk levels may be calculated by use of the Guidelines. The risk estimate range is presented for information purposes and does not represent an Agency judgment on an "acceptable" risk level.

For the maximum protection of human health from the potential carcinogenic effects due to exposure of gamma-HCH through ingestion of contaminated water and contaminated aquatic organisms, the ambient water concentrations should be zero based on the non-threshold assumption for this chemical. However, zero level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk over the lifetime are estimated at 10^{-5}, 10^{-6}, and 10^{-7}. The corresponding criteria are 186 ng/l, 18.6 ng/l, and 1.86 ng/l, respectively. If the above estimates are made for consumption of aquatic organisms only, excluding consumption of water, the levels are 625 ng/l, 62.5 ng/l, 6.25 ng/l, respectively. Other concentrations representing different risk levels may be calculated by use of the Guidelines. The risk estimate range is presented for information purposes and does not represent an Agency judgment on an "acceptable" risk level.

Using the present guidelines, a satisfactory criterion cannot be derived at this time due to the insufficiency in the available data for delta-HCH.

Using the present guidelines, a satisfactory criterion cannot be derived at this time due to the insufficiency in the available data for epsilon-HCH.

Hexachlorocyclopentadiene

Freshwater Aquatic Life

The available data for hexachlorocyclopentadiene indicate that acute and chronic toxicity to freshwater aquatic life occurs at concentrations as low as 7.0 and 5.2 µg/l, respectively, and would occur at lower concentrations among species that are more sensitive than those tested.

Saltwater Aquatic Life

The available data to hexachlorocyclopentadiene indicate that acute toxicity to saltwater aquatic life occurs at concentrations as low as 7.0 µg/l and would occur at lower concentrations among species that are more sensitive than those tested. No data are available concerning the chronic toxicity of hexachlorocyclopentadiene to sensitive saltwater aquatic life.

Human Health

For comparison purposes, two approaches were used to derive criterion levels for hexachlorocyclopentadiene. Based on available toxicity data, for the protection of public health, the derived level is 206 µg/l. Using available organoleptic data, for controlling undesirable taste and odor quality of ambient water, the estimated level is 1.0 µg/l. It should be recognized that organoleptic data as a basis for establishing a water quality criterion have limitations and have no demonstrated relationship to potential adverse human health effects.

Isophorone

Freshwater Aquatic Life

The available data for isophorone indicate that acute toxicity to freshwater aquatic life ocurs at concentrations as low as 117,000 µg/l and would occur at lower concentrations among species that are more sensitive than those tested. No data are available concerning the chronic toxicity of isophorone to sensitive freshwater aquatic life.

Saltwater Aquatic Life

The available data for isophorone indicate that acute toxicity to saltwater aquatic life occurs at concentrations as low as 12,900 µg/l and would occur at lower concentrations among species that are more sensitive than those tested. No data are available concerning the chronic toxicity of isophorone to sensitive saltwater aquatic life.

Human Health

For the protection of human health from the toxic properties of isophorone ingested through water and contaminated aquatic organisms, the ambient water criterion is determined to be 5.2 mg/l.

For the protection of human health from the toxic properties of isophorone ingested through contaminated aquatic organisms alone, the ambient water criterion is determined to be 520 mg/l.

Lead

Freshwater Aquatic Life

For total recoverable lead the criterion (in µg/l) to protect freshwater aquatic life as derived using the Guidelines is the numerical value given by $e^{(2.35[\ln(\text{hardness})]-9.48)}$ as a 24-hour average and the concentration (in µg/l) should not exceed the numerical value given by $e^{(1.22[\ln(\text{hardness})]-0.47)}$ at any time. For example, at hardnesses of 50, 100, and 200 mg/l as $CaCO_3$, the criteria are 0.75, 3.8, and 20 µg/l, respectively, as 24-hour averages, and the concentrations should not exceed 74, 170, and 400 µg/l, respectively, at any time.

Saltwater Aquatic Life

The available data for total recoverable lead indicate that acute and chronic toxicity to saltwater aquatic life occur at concentrations as low as 668 and 25 µg/l, respectively, and would occur at lower concentrations among species that are more sensitive than those tested.

Human Health

The ambient water quality criterion for lead is recommended to be identical to the existing drinking water standard which is 50 µg/l. Analysis of the toxic effects data resulted in a calculated level which is protective to human health against the ingestion of contaminated water and contaminated aquatic organisms. The calculated value is comparable to the present standard. For this reason a selective criterion based on exposure solely from consumption of 6.5 grams of aquatic organisms was not derived.

Mercury

Freshwater Aquatic Life

For total recoverable mercury the criterion to protect freshwater aquatic life as derived using the Guidelines is 0.00057 µg/l as a 24-hour average and the concentration should not exceed 0.0017 µg/l at any time.

Saltwater Aquatic Life

For total recoverable mercury the criterion to protect saltwater aquatic life as derived using the Guidelines is 0.025 µg/l as a 24-hour average and the concentration should not exceed 3.7 µg/l at any time.

Human Health

For the protection of human health from the toxic properties of mercury ingested through water and contaminated aquatic organisms, the ambient water criterion is determined to be 144 ng/l.

For the protection of human health from the toxic properties of mercury ingested through contaminated aquatic organisms alone, the ambient water criterion is determined to be 146 ng/l.

Note.—These values include the consumption of freshwater, estuarine, and marine species.

Naphthalene

Freshwater Aquatic Life

The available data to naphthalene indicate that acute and chronic toxicity to freshwater aquatic life occur at concentrations as low as 2,300 and 620 μg/l, respectively, and would occur at lower concentrations among species that are more sensitive than those tested.

Saltwater Aquatic Life

The available data for naphthalene indicate that acute toxicity to saltwater aquatic life occurs at concentrations as low as 2,350 μg/l and would occur at lower concentrations among species that are more sensitive than those tested. No data are available concerning the chronic toxicity of naphthalene to sensitive saltwater aquatic life.

Human Health

Using the present guidelines, a satisfactory criterion cannot be derived at this time due to the insufficiency in the available data for naphthalene.

Nickel

Freshwater Aquatic Life

For total recoverable nickel the criterion (in μg/l) to protect freshwater aquatic life as derived using the Guidelines is the numerical value given by $e^{(0.76 [\ln (\text{hardness})] + 1.06)}$ as a 24-hour average and the concentration (in μg/l) should not exceed the numerical value given by $e^{(0.76[\ln (\text{hardness})] + 4.02)}$ at any time. For example, at hardnesses of 50, 100, and 200 mg/l as $CaCO_3$ the criteria are 56, 96, and 160 μg/l, respectively, as 24-hour averages, and the concentrations should not exceed 1,100, 1,800, and 3,100 μg/l, respectively, at any time.

Saltwater Aquatic Life

For total recoverable nickel the criterion to protect saltwater aquatic life as derived using the Guidelines is 7.1 μg/l as a 24-hour average and the concentration should not exceed 140 μg/l at any time.

Human Health

For the protection of human health from the toxic properties of nickel ingested through water and contaminated aquatic organisms, the ambient water criterion is determined to be 13.4 μg/l.

For the protection of human health from the toxic properties of nickel ingested through contaminated aquatic organisms alone, the ambient water criterion is determined to be 100 μg/l.

Nitrobenzene

Freshwater Aquatic Life

The available data for nitrobenzene indicate that acute toxicity to freshwater aquatic life occurs at concentrations as low as 27,000 μg/l and would occur at lower concentrations among species that are more sensitive than those tested. No definitive data are available concerning the chronic toxicity of nitrobenzene to sensitive freshwater aquatic life.

Saltwater Aquatic Life

The available data for nitrobenzene indicate that acute toxicity to saltwater aquatic life occurs at concentrations as low as 6,680 μg/l and would occur at lower concentrations among species that are more sensitive than those tested. No data are available concerning the chronic toxicity of nitrobenzene to sensitive saltwater aquatic life.

Human Health

For comparison purposes, two approaches were used to derive criterion levels for nitrobenzene. Based on available toxicity data, for the protection of public health, the derived level is 19.8 mg/l. Using available organoleptic data, for controlling undesirable taste and odor quality of ambient water, the estimated level is 30 μg/l. It should be recognized that organoleptic data as a basis for establishing a water quality criteria have limitations and have no demonstrated relationship to potential adverse human health effects.

Nitrophenols

Freshwater Aquatic Life

The available data for nitrophenols indicate that acute toxicity to freshwater aquatic life occurs at concentrations as low as 230 μg/l and would occur at lower concentrations among species that are more sensitive than those tested. No data are available concerning the chronic toxicity of nitrophenols to sensitive freshwater aquatic life but toxicity to one species of algae occurs at concentrations as low as 150 μg/l.

Saltwater Aquatic Life

The available data for nitrophenols indicate that acute toxicity to saltwater aquatic life occurs at concentrations as low as 4,850 μg/l and would occur at lower concentrations among species that are more sensitive than those tested. No data are available concerning the chronic toxicity of nitrophenols to sensitive saltwater aquatic life.

Human Health

For the protection of human health from the toxic properties of 2,4-dinitro-o-cresol ingested through water and contaminated aquatic organisms, the ambient water criterion is determined to be 13.4 μg/l.

For the protection of human health from the toxic properties of 2,4-dinitro-o-cresol ingested through contaminated aquatic organisms alone, the ambient water criterion is determined to be 765 μg/l.

For the protection of human health from the toxic properties of dinitrophenol ingested through water and contaminated aquatic organisms, the ambient water criterion is determined to be 70 μg/l.

For the protection of human health from the toxic properties of dinitrophenol ingested through contaminated aquatic organisms alone, the ambient water criterion is determined to be 14.3 mg/l.

Using the present guidelines, a satisfactory criterion cannot be derived at this time due to the insufficiency in the available data for mononitrophenol.

Using the present guidelines, a satisfactory criterion cannot be derived at this time due to the insufficiency in the available data for tri-nitrophenol.

Nitrosamines

Freshwater Aquatic Life

The available data for nitrosamines indicate that acute toxicity to freshwater aquatic life occurs at concentrations as low as 5,850 μg/l and would occur at lower concentrations among species that are more sensitive than those tested. No data are available concerning the chronic toxicity of nitrosamines to sensitive freshwater aquatic life.

Saltwater Aquatic Life

The available data for nitrosamines indicate that acute toxicity to saltwater aquatic life occurs at concentrations as low as 3,300,000 μg/l and would occur at lower concentrations among species that are more sensitive than those tested. No data are available concerning the chronic toxicity of nitrosamines to sensitive saltwater aquatic life.

Human Health

For the maximum protection of human health from the potential carcinogenic effects due to exposure of n-nitrosodimethylamine through ingestion of contaminated water and contaminated aquatic organisms, the ambient water concentration should be zero based on the non-threshold assumption for this chemical. However, zero level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk, over the lifetimes are estimated at 10^{-5}, 10^{-6}, and 10^{-7}. The corresponding criteria are 14 ng/l, 1.4 ng/l, and .14 ng/l, respectively. If the above estimates are made for consumption of aquatic organisms only, excluding consumption of water, the levels are 160,000 ng/l, 16,000 ng/l, and 1,600 ng/l, respectively. Other concentrations representing different risk levels may be calculated by use of the Guidelines. The risk estimate range is presented for information purposes and does not represent an Agency judgment on an "acceptable" risk level.

For the maximum protection of human health from the potential carcinogenic effects due to exposure of n-nitrosodiethylamine through ingestion of contaminated water and contaminated aquatic organisms, the ambient water concentration should be zero based on the non-threshold assumption for this chemical. However, zero level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk, over the lifetimes are estimated at 10^{-5}, 10^{-6}, and 10^{-7}. The corresponding criteria are 8 ng/l, 0.8 ng/l, and 0.08 ng/l, respectively. If the above estimates are made for consumption of aquatic organisms only, excluding consumption of water, the levels are 12,400 ng/l, 1,240 ng/l, and 124 ng/l, respectively. Other concentrations representing different risk levels may be calculated by use of the Guidelines. The risk estimate range is presented for information purposes and does not represent an Agency judgment on an "acceptable" risk level.

For the maximum protection of human health from the potential carcinogenic effects due to exposure in n-nitrosodi-n-butylamine through ingestion of contaminated water and contaminated aquatic organisms, the ambient water concentration should be zero based on the non-threshold assumption for this chemical. However, zero level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk, over the lifetimes are estimated at 10^{-5}, 10^{-6}, and 10^{-7}. The corresponding criteria are 64 ng/l 6.4 ng/l and .064 ng/l, respectively. If the above estimates are made for consumption of aquatic organisms only, excluding consumption of water, the levels are 5,868 ng/l, 587 ng/l, and 58.7 ng/l, respectively. Other concentrations representing different risk levels may be calculated by use of the Guidelines. The risk estimate range is presented for information purposes and does not represent an Agency judgment on an "acceptable" risk level.

For the maximum protection of human health from the potential carcinogenic effects due to exposure in n-nitrosodiphenylamine through ingestion of contaminated water and contaminated aquatic organisms, the ambient water concentration should be zero based on the non-threshold assumption for this chemical. However, zero level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk, over the lifetimes are estimated at 10^{-5}, 10^{-6}, and 10^{-7}. The corresponding criteria are 49,000 ng/l 4,900 ng/l and 490 ng/l, respectively. If the above estimates are made for consumption of aquatic organisms only, excluding consumption of water, the levels are 161,000 ng/l, 16,100 ng/l, and 1,610 ng/l, respectively. Other concentrations representing different risk levels may be calculated by use of the Guidelines. The risk estimate range is presented for information purposes and does not represent an Agency judgment on an "acceptable" risk level.

For the maximum protection of human health from the potential carcinogenic effects due to exposure in n-nitrosopyrrolidine through ingestion of contaminated water and contaminated aquatic organisms, the ambient water concentration should be zero based on the non-threshold assumption for this chemical. However, zero level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk, over the lifetimes are estimated at 10^{-5}, 10^{-6}, and 10^{-7}. The corresponding criteria are 160 ng/l 16.0 ng/l and 1.60 ng/l, respectively. If the above estimates are made for consumption of aquatic organisms only, excluding consumption of water, the levels are 919,000 ng/l, 91,900 ng/l, and 9,190 ng/l, respectively. Other concentrations representing different risk levels may be calculated by use of the Guidelines. The risk estimate range is presented for information purposes and does not represent an Agency judgment on an "acceptable" risk level.

Pentachlorophenol

Freshwater Aquatic Life

The available data for pentachlorophenol indicate that acute and chronic toxicity to freshwater aquatic life occur at concentrations as low as 55 and 3.2 μg/l, respectively, and would occur at lower concentrations among species that are more sensitive than those tested.

Saltwater Aquatic Life

The available data for pentachlorophenol indicate that acute and chronic toxicity to saltwater aquatic life occur at concentrations as low as 53 and 34 μg/l, respectively, and would occur at lower concentrations among species that are more sensitive than those tested.

Human Health

For comparison purposes, two approaches were used to derive criterion levels for pentachlorophenol. Based on available toxicity data, for the protection of public health, the derived level is 1.01 mg/l. Using available organoleptic data, for controlling undesirable taste and odor quality of ambient water, the estimated level is 30 μg/l. It should be recognized that organoleptic data as a basis for establishing a water quality criterion have limitations and have no demonstrated relationship to potential adverse human health effects.

Phenol

Freshwater Aquatic Life

The available data for phenol indicate that acute and chronic toxicity to freshwater aquatic life occur at concentrations as low as 10,200 and 2,560 μg/l, respectively, and would occur at lower concentrations among species that are more sensitive than those tested.

Saltwater Aquatic Life

The available data for phenol indicate that atute toxicity to saltwater aquatic life occurs at concentrations as low as 5,800 ug/l and would occur at lower concentrations among species that are more sensitive than those tested. No data are available concerning the chronic toxicity of phenol to sensitive saltwater aquatic life.

Human Health

For comparison purposes, two approaches were used to derive criterion levels for phenol. Based on available toxicity data, for the protection of public health, the derived level is 3.5 mg/l. Using available organoleptic data, for controlling undesirable taste and odor quality of ambient water, the estimated level is 0.3 mg/l. It should be recognized that organoleptic data as a basis for establishing a water quality criterion have limitations and have no demonstrated relationship to potential adverse human health effects.

Phthalate Esters

Freshwater Aquatic Life

The available data for phthalate esters indicate that acute and chronic toxicity to freshwater aquatic life occur at concentrations as low as 940 and 3 µg/l, respectively, and would occur at lower concentrations among species that are more sensitive than those tested.

Saltwater Aquatic Life

The available data for phthalate esters indicate that acute toxicity to saltwater aquatic life occurs at concentrations as low as 2944 µg/l and would occur at lower concentrations among species that are more sensitive than those tested. No data are available concerning the chronic toxicity of phthalate esters to sensitive saltwater aquatic life but toxicity to one species of algae occurs at concentrations as low as 3.4 µg/l.

Human Health

For the protection of human health from the toxic properties of dimethyl-phthalate ingested through water and contaminated aquatic organisms, the ambient water criterion is determined to be 313 mg/l.

For the protection of human health from the toxic properties of dimethyl-phthalate ingested through contaminated aquatic organisms alone, the ambient water criterion is determined to be 2.9 g/l.

For the protection of human health from the toxic properties of diethyl-phthalate ingested through water and contaminated aquatic organisms, the ambient water criterion is determined to be 350 mg/l.

For the protection of human health from the toxic properties of diethyl-phthalate ingested through contaminated aquatic organisms alone, the ambient water criterion is determined to be 1.8 g/l.

For the protection of human health from the toxic properties of dibutyl-phthalate ingested through water and contaminated aquatic organisms, the ambient water criterion is determined to be 34 mg/l.

For the protection of human health from the toxic properties of dibutyl-phthalate ingested through contaminated aquatic organisms alone, the ambient water criterion is determined to be 154 mg/l.

For the protection of human health from the toxic properties of di-2-ethylhexyl-phthalate ingested through water and contaminated aquatic organisms, the ambient water criterion is determined to be 15 mg/l.

For the protection of human health from the toxic properties of di-2-ethylhexyl-phthalate ingested through contaminated aquatic organisms alone, the ambient water criterion is determined to be 50 mg/l.

Polychlorinated Biphenyls

Freshwater Aquatic Life

For polychlorinated biphenyls the criterion to protect freshwater aquatic life as derived using the Guidelines is 0.014 µg/l as a 24-hour average. The available data indicate that acute toxicity to freshwater aquatic life probably will only occur at concentrations above 2.0 µg/l and that the 24-hour average should provide adequate protection against acute toxicity.

Saltwater Aquatic Live

For polychlorinated biphenyls the criterion to protect saltwater aquatic life as derived using the Guidelines is 0.030 µg/l as a 24-hour average. The available data indicate that acute toxicity to saltwater aquatic life probably will only occur at concentrations above 10 µg/l and that the 24-hour average should provide adequate protection against acute toxicity.

Human Health

For the maximum protection of human health from the potential carcinogenic effects due to exposure of PCBs through ingestion of contaminated water and contaminated aquatic organisms, the ambient water concentration should be zero based on the non-threshold assumption for this chemical. However, zero level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk over the lifetime are estimated at 10^{-5}, 10^{-6}, and 10^{-7}. The corresponding criteria are .79 ng/l, 0.79 ng/l, and .0079 ng/l, respectively. If the above estimates are made for consumption of aquatic organisms only, excluding consumption of water, the levels are .79 ng/l, .079 ng/l, and .0079 ng/l, respectively. Other concentrations representing different risk levels may be calculated by use of the Guidelines. The risk estimate range is presented for information purposes and does not represent an Agency judgment on an "acceptable" risk level.

Polynuclear Aromatic Hydrocarbons (PAHs)

Freshwater Aquatic Life

The limited freshwater data base available for polynuclear aromatic hydrocarbons, mostly from short-term bioconcentration studies with two compounds, does not permit a statement concerning acute or chronic toxicity.

Saltwater Aquatic Life

The available data for polynuclear aromatic hydrocarbons indicate that acute toxicity to saltwater aquatic life occurs at concentrations as low as 300 ug/l and would occur at lower concentrations among species that are more sensitive than those tested. No data are available concerning the chronic toxicity of polynuclear aromatic hydrocarbons to sensitive saltwater aquatic life.

Human Health

For the maximum protection of human health from the potential carcinogenic effects due to exposure of PAHs through ingestion of contaminated water and contaminated aquatic organisms, the ambient water concentration should be zero based on the non-threshold assumption for this chemical. However, zero level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk over the lifetime are estimated at 10^{-5}, 10^{-6}, and 10^{-7}. The corresponding criteria are 28 ng/l, 2.8 ng/l, and .28 ng/l, respectively. If the above estimates are made for consumption of aquatic organisms only, excluding consumption of water, the levels are 311 ng/l, 31.1 ng/l, and 3.11 ng/l, respectively. Other concentrations representing different risk levels may be calculated by use of the Guidelines. The risk estimate range is presented for information purposes and does not represent an Agency judgment on an "acceptable" risk level.

Selenium

Freshwater Aquatic Life

For total recoverable inorganic selenite the criterion to protect freshwater aquatic life as derived using the Guidelines is 35 µg/l as a 24-hour average and the concentration should not exceed 260 µg/l at any time.

The available data for inorganic selenate indicate that acute toxicity to freshwater aquatic life occurs at concentrations as low as 760 µg/l and would occur at lower concentrations among species that are more sensitive than those tested. No data are available concerning the chronic toxicity of inorganic selenate to sensitive freshwater aquatic life.

Saltwater Aquatic Life

For total recoverable inorganic selenite the criterion to protect saltwater aquatic life as derived using the Guidelines is 54 μg/l as a 24-hour average and the concentration should not exceed 410 μg/l at any time.

No data are available concerning the toxicity of inorganic selenate to saltwater aquatic life.

Human Health

The ambient water quality criterion for selenium is recommended to be identical to the existing drinking water standard which is 10 μg/l. Analysis of the toxic effects data resulted in a calculated level which is protective of human health against the ingestion of contaminated water and contaminated aquatic organisms. The calculated value is comparable to the present standard. For this reason a selective criterion based on exposure solely from consumption of 6.5 grams of aquatic organisms was not derived.

Silver

Freshwater Aquatic Life

For freshwater aquatic life the concentration (in μg/l) of total recoverable silver should not exceed the numerical value given by "e[1.72(ln (hardness)-6.52)]" at any time. For example, at hardnesses of 50, 100, 200 mg/l as $CaCO_3$ the concentration of total recoverable silver should not exceed 1.2, 4.1, and 13 μg/l, respectively, at any time. The available data indicate that chronic toxicity to freshwater aquatic life may occur at concentrations as low as 0.12 μg/l.

Saltwater Aquatic Life

For saltwater aquatic life the concentration of total recoverable silver should not exceed 2.3 μg/l at any time. No data are available concerning the chronic toxicity of silver to sensitive saltwater aquatic life.

Human Health

The ambient water quality criterion for silver is recommended to be identical to the existing drinking water standard which is 50 μg/l. Analysis of the toxic effects data resulted in a calculated level which is protective of human health against the ingestion of contaminated water and contaminated aquatic organisms. The calculated value is comparable to the present standard. For this reason a selective criterion based on exposure solely from consumption of 6.5 grams of aquatic organisms was not derived.

Tetrachloroethylene

Freshwater Aquatic Life

The available data for tetrachloroethylene indicate that acute and chronic toxicity to freshwater aquatic life occur at concentrations as low as 5,280 and 840 μg/l, respectively, and would occur at lower concentrations among species that are more sensitive than those tested.

Saltwater Aquatic Life

The available data for tetrachloroethylene indicate that acute and chronic toxicity to saltwater aquatic life occur at concentrations low as 10,200 and 450 μg/l, respectively, and would occur at lower concentrations among species that are more sensitive than those tested.

Human Health

For the maximum protection of human health from the potential carcinogenic effects due to exposure of tetrachloroethylene through ingestion of contaminated water and contaminated aquatic organisms, the ambient water concentration should be zero based on the non-threshold assumption for this chemical. However, zero level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk over the lifetime are estimated at 10^{-5}, 10^{-6}, and 10^{-7}. The corresponding criteria are 8 μg/l, .8 μg/l, and .08 μg/l, respectively. If the above estimates are made for consumption of aquatic organisms only, excluding consumption of water, the levels are 88.5 μg/l, 8.85 μg/l, and .88 μg/l, respectively. Other concentrations representing different risk levels may be calculated by use of the Guidelines. The risk estimate range is presented for information purposes and does not represent an Agency judgment on an "acceptable" risk level.

Thallium

Freshwater Aquatic Life

The available data for thallium indicate that acute and chronic toxicity to freshwater aquatic life occur at concentrations as low as 1,400 and 40 μg/l, respectively, and would occur at lower concentrations among species that are more sensitive than those tested. Toxicity to one species of fish occurs at concentrations as low as 20 μg/l after 2,600 hours of exposure.

Saltwater Aquatic Life

The available data for thallium indicate that acute toxicity to saltwater aquatic life occurs at concentrations as low as 2,130 μg/l and would occur at lower concentrations among species that are more sensitive than those tested. No data are available concerning the chronic toxicity of thallium to sensitive saltwater aquatic life.

Human Health

For the protection of human health from the toxic properties of thallium ingested through water and contaminated aquatic organisms, the ambient water criterion is determined to be 13 μg/l.

For the protection of human health from the toxic properties of thallium ingested through contaminated aquatic organisms alone, the ambient water criterion is determined to be 48 μg/l.

Toluene

Freshwater Aquatic Life

The available data for toluene indicate that acute toxicity to freshwater aquatic life occurs at concentrations as low as 17,500 μg/l and would occur at lower concentrations among species that are more sensitive than those tested. No data are available concerning the chronic toxicity of toluene to sensitive freshwater aquatic life.

Saltwater Aquatic Life

The available data for toluene indicate that acute and chronic toxicity to saltwater aquatic life occur at concentrations as low as 6,300 and 5,000 μg/l, respectively, and would occur at lower concentrations among species that are more sensitive than those tested.

Human Health

For the protection of human health from the toxic properties of toluene ingested through water and contaminated aquatic organisms, the ambient water criterion is determined to be 14.3 mg/l.

For the protection of human health from the toxic properties of toluene ingested through contaminated aquatic organisms alone, the ambient water criterion is determined to be 424 mg/l.

Toxaphene

Freshwater Aquatic Life

For toxaphene the criterion to protect freshwater aquatic life as derived using the Guidelines is 0.013 μg/l as a 24-hour average and the concentration should not exceed 1.6 μg/l at any time.

Saltwater Aquatic Life

For saltwater aquatic life the concentration of toxaphene should not exceed 0.070 μg/l at any time. No data are available concerning the chronic toxicity of toxaphene to sensitive saltwater aquatic life.

Human Health

For the maximum protection of human health from the potential carcinogenic effects due to exposure of toxaphene through ingestion of contaminated water and contaminated aquatic organisms, the ambient water concentration should be zero based on the non-threshold assumption for this chemical. However, zero level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk over the lifetime are estimated at 10^{-5}, 10^{-6}, and 10^{-7}. The corresponding criteria are 7.1 ng/l, .71 ng/l, and .07 ng/l, respectively. If the above estimates are made for consumption of aquatic organisms only, excluding consumption of water, the levels are 7.3 ng/l, .73 ng/l, and .07 ng/l, respectively. Other concentrations representing different risk levels may be calculated by use of the Guidelines. The risk estimate range is presented for information purposes and does not represent an Agency judgment on an "acceptable" risk level.

Trichloroethylene

Freshwater Aquatic Life

The available data for trichloroethylene indicate that acute toxicity to freshwater aquatic life occurs at concentrations as low as 45,000 μg/l and would occur at lower concentrations among species that are more sensitive than those tested. No data are available concerning the chronic toxicity of trichloroethylene to sensitive freshwater aquatic life but adverse behavioral effects occurs to one species at concentrations as low as 21,900 μg/l.

Saltwater Aquatic Life

The available data for trichloroethylene indicate that acute toxicity to saltwater aquatic life occurs at concentrations as low as 2,000 μg/l and would occur at lower concentrations among species that are more sensitive than those tested. No data are available concerning the chronic toxicity of trichloroethylene to sensitive saltwater aquatic life.

Human Health

For the maximum protection of human health from the potential carcinogenic effects due to exposure of trichloroethylene through ingestion of contaminated water and contaminated aquatic organisms, the ambient water concentration should be zero based on the non-threshold assumption for this chemical. However, zero level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk over the lifetime are estimated at 10^{-5}, 10^{-6}, and 10^{-7}. The corresponding criteria are 27 μg/l, 2.7 μg/l, and .27 μg/l, respectively. If the above estimates are made for consumption of aquatic organisms only, excluding consumption of water, the levels are 807 μg/l, 80.7 μg/l, and 8.07 μg/l, respectively. Other concentrations representing different risk levels may be calculated by use of the Guidelines. The risk estimate range is presented for information purposes and does not represent an Agency judgment on an "acceptable" risk level.

Vinyl Chloride

Freshwater Aquatic Life

No freshwater organisms have been tested with vinyl chloride and no statement can be made concerning acute or chronic toxicity.

Saltwater Aquatic Life

No saltwater organisms have been tested with vinyl chloride and no statement can be made concerning acute or chronic toxicity.

Human Health

For the maximum protection of human health from the potential carcinogenic effects due to exposure of vinyl chloride through ingestion of contaminated water and contaminated aquatic organisms, the ambient water concentration should be zero based on the non-threshold assumption for this chemical. However, zero level may not be attainable at the present time. Therefore, the levels which may result in incremental increase of cancer risk over the lifetime are estimated at 10^{-5}, 10^{-6}, and 10^{-7}. The corresponding criteria are 20 μg/l, 2.0 μg/l, and .2 μg/l, respectively. If the above estimates are made for consumption of aquatic organisms only, excluding consumption of water, the levels are 5,240 μg/l, 525 μg/l, and 52.5 μg/l, respectively. Other concentrations representing different risk levels may be calculated by use of the Guidelines. The risk estimate range is presented for information purposes and does not represent an Agency judgment on an "acceptable" risk level.

Zinc

Freshwater Aquatic Life

For total recoverable zinc the criterion to protect freshwater aquatic life as derived using the Guidelines is 47 μg/l as a 24-hour average and the concentration (in μg/l) should not exceed the numerical value given by $e^{(0.83 [\ln(\text{hardness})] + 1.95)}$ at any time. For example, at hardnesses of 50, 100, and 200 mg/l as $CaCO_3$ the concentration of total recoverable zinc should not exceed 180, 320, and 570 μg/l at any time.

Saltwater Aquatic Life

For total recoverable zinc the criterion to protect saltwater aquatic life as derived using the Guidelines is 58 μg/l as a 24-hour average and the concentration should not exceed 170 μg/l at any time.

Human Health

Sufficient data is not available for zinc to derive a level which would protect against the potential toxicity of this compound. Using available organoleptic data, for controlling undesirable taste and odor quality of ambient water, the estimated level is 5 mg/l. It should be recognized that organoleptic data as a basis for establishing a water quality criteria have limitations and have not demonstrated relationship to potentia adverse human health effects.

Appendix B—Guidelines for Deriving Water Quality Criteria for the Protection of Aquatic Life and Its Uses

Introduction

This version of the Guidelines provides clarifications, additional details, and technical and editorial changes in the last version published in the **Federal Register** [44 FR 15970 (March 15, 1979)]. This version incorporates changes resulting from comments on previous versions and from experience gained during U.S. EPA's use of the previous versions. Future versions of the Guidelines will incorporate new ideas and data as their usefulness is demonstrated.

Criteria may be expressed in several forms. The numerical form is commonly used, but descriptive and procedural forms can be used if numerical criteria are not possible or desirable. The purpose of these Guidelines is to describe an objective, internally consistent and appropriate way of deriving numerical water quality criteria for the protection of the uses of, as well as the presence of, aquatic organisms.

A numerical criterion might be thought of as an estimate of the highest concentration of a substance in water which does not present a significant risk to the aquatic organisms in the water and their uses. Thus the Guidelines are intended to derive criteria which will protect aquatic communities by protecting most of the species and their uses most of the time, but not necessarily all of the species all of the time. Aquatic communities can tolerate some stress and occasional adverse effects on a few species, and so total protection of all of the species all of the time is not necessary. Rather, the Guidelines attempt to provide a reasonable and adequate amount of protection with only a small possibility of considerable overprotection or underprotection. Within these constraints, it seems appropriate to err on the side of overprotection.

The numerical aquatic life criteria derived using the Guidelines are expressed as two numbers, rather than the traditional one number, so that the criteria can more accurately reflect toxicological and practical realities. The combination of both a maximum value and a 24-hour average value is designed to provide adequate protection of aquatic life and its uses from acute and chronic toxicity to animals, toxicity to plants and bioconcentration by aquatic organisms without being as restrictive as a one-number criterion would have to be to provide the same amout of protection. The only way to assure the same degree of protection with a one-number criterion would be to use the 24-hour average as a concentration that is not to be exceeded at any time in any place.

The two-number criterion is intended to identify an average pollutant concentration which will produce a water qualtiy generally suited to the maintenance of aquatic life and its uses while restricting the extent and duration of excursions over the average so that the total exposure will not cause unacceptable adverse effects. Merely specifying an average value over a time period is insufficient, unless the period of time is rather short, because of concentration higher than the average value can kill or cause substantial damage in short periods. Furthermore, for some substances the effect of intermittent high exposures is cumulative. It is therefore necessary to place an upper limit on pollutant concentrations to which aquatic organisms might be exposed, especially when the maximum value is not much higher than the average value. For some substances the maximum may be so much higher than the 24-hour average that in any real-world situation the maximum will never be reached if the 24-hour average is achieved. In such cases the 24-hour average will be limiting and the maximum will have no practical significance, except to indicate that elevated concentrations are acceptable as long as the 24-hour average is achieved.

These Guidelines have been developed on the assumption that the results of laboratory tests are generally useful for predicting what will happen in field situations. The resulting criteria are meant to apply to most bodies of water in the United States, except for the Great Salt Lake. All aquatic organisms and their common uses are meant to be considered, but not necessarily protected, if relevant data are available, with at least one specific exception. This exception is the accumulation of residues of organic compounds in the siscowet subspecies of lake trout which occurs in Lake Superior and contains up to 67% fat in the fillets (Thurston, C.E., 1962, Physical Characteristics and Chemical Composition of Two Subspecies of Lake Trout, J. Fish. Res. Bd. Canada 19:39–44). Neither siscowet nor organisms in the Great Salt Lake are intentionally protected by these Guidelines because both may be too atypical.

With appropriate modifications these Guidelines can be used to derive criteria for any specified geographical area, body of water (such as the Great Salt Lake), or group of similar bodies of water. Thus with appropriate modifications the Guidelines can be used to derive national, state, or local criteria if adequate information is available concerning the effects of the substance of concern on appropriate species and their uses. However, the basic concepts described in the Guidelines should be modified only when sound scientific evidence indicates that a criterion produced using the Guidelines would probably significantly overprotect or underprotect the presence or uses of aquatic life.

Criteria produced by these Guidelines are not enforceable numbers. They may be used in developing enforceable numbers, such as water quality standards and effluent standards. However, the development of standards may take into account additional factors such as social, legal, economic, and hydrological considerations, the environmental and analytical chemistry of the substance, the extrapolation from laboratory data to field situations, and the relationship between the species for which data are available and the species which are to be protected.

Because fresh water and salt water (including both estuarine and marine waters) have basically different chemical compositions and because freshwater and saltwater species rarely inhabit the same water simultaneously, separate criteria should be derived for these two kinds of waters. However, for some substances sufficient data may not be available to allow derivation of one or both of these criteria using the Guidelines.

These Guidelines are meant to be used after a decision is made that a criterion is needed for a substance. The Guidelines do not address the rationale for making that decision. If the potential for adverse effects on aquatic life and its uses are part of the basis for deciding whether or not a criterion is needed for a substance, these Guidelines may be helpful in the collection and interpretation of relevant data.

I. Define the Substance for Which the Criterion Is To Be Derived

A. Each separate chemical which would not ionize significantly in most natural bodies of water should usually be considered a separate substance, except possibly for structurally similar organic compounds that only differ in the number and location of atoms of a specific halogen, and only exist in large quantities as commercial mixtures of the various compounds, and apparently have similar chemical, biological, and toxicological properties.

B. For chemicals, which would ionize significantly in most natural bodies of water, such as inorganic salts, organic acids and phenols, all forms that would be in chemical equilibrium should usually be considered one substance. For metals, each different valence and each different covalently bonded organometallic compound should usually be considered a separate substance.

C. The definition of the substance may also need to take into account the analytical chemistry and fate of the substance.

II. Collect and Review Available Data

A. Collect all available data on the substance concerning (1) toxicity to, and bioaccumulation by, aquatic animals and plants, (2) FDA action levels, and (3) chronic feeding studies with wildlife.

B. Discard all data that are not available in hard copy (publication, manuscript, letter, memorandum, etc.) with enough supporting information to indicate that acceptable test procedures were used and that the results are reliable. Do not assume that all published data are acceptable.

C. Discard questionable data. For example, discard data from tests for which no control treatment existed, in which too many organisms in the control treatment died or showed signs of stress or disease, or in which distilled or deionized water was used as the dilution water for aquatic organisms. Discard data on formulated mixtures and emulsifiable concentrates of the substance of concern, but not necessarily data on technical grade material.

D. Do not use data obtained using:

1. Brine shrimp, because they usually only occur naturally in water with salinity greater than 35 g/kg.

2. Species that do not have reproducing wild populations resident in—but not necessarily native to—North America. Resident North American species of fishes are defined as those listed in "A List of Common and Scientific Names of Fishes from the United States and Canada", 3rd ed., Special Publication No. 6, American Fisheries Society, Washington, D.C., 1970. Data obtained with non-resident species can be used to indicate relationships and possible problem areas, but cannot be used in the derivation of criteria.

3. Organisms that were previously exposed to significant concentrations of the test material or other pollutants.

III. Minimum Data Base

A. A minimum amount of data should be available to help ensure that each of the four major kinds of possible adverse effects receives some consideration. Results of acute and chronic toxicity tests with a reasonable number and variety of aquatic animals are necessary so that data available for tested species can be considered a useful indication of the sensitivities of the numerous untested species. The requiurements concerning toxicity to aquatic plants are less stringent because procedures for conducting tests with plants are not as well developed and the interpretation of the results is more questionable. Data concerning bioconcentration by aquatic organisms can only be used if other relevant data are available.

B. To derive a criterion for freshwater aquatic life, the following should be available:

1. Acute tests (see Section IV) with freshwater animals in at least eight different families provided that of the eight species:

—at least one is a salmonid fish
—at least one is a non-salmonid fish
—at least one is a planktonic crustacean
—at least one is a benthic crustacean
—at least one is a benthic insect
—at least one of the benthic species is a detritivore

2. Acute-chronic ratios (see Section VI) for at least three species of aquatic animals provided that of the three species:

—at least one is a fish
—at least one is an invertebrate
—at least one is a freshwater species (the other two may be saltwater species)

3. At least one test with a freshwater alga or a chronic test with a freshwater vascular plant (see Section VIII). If plants are among the aquatic organisms that are most sensitive to the substance, tests with more than one species should be available.

4. At least one acceptable bioconcentration factor determined with an aquatic animal species, if a maximum permissible tissue concentration is available (see Section IX).

C. To derive a criterion for saltwater aquatic life, the following should be available:

1. Acute tests (see Section IV) with saltwater animals in at least eight different families provided that of the eight species:

—at least two different fish families are included
—at least five different invertebrate families are included
—either the Mysidae or Penaeidae family or both are included
—at least one of the invertebrate families is in a phylum other than Arthropoda

2. Acute-chronic ratios (see Section VI) for at least three species of aquatic animals provided that of the three species:

—at least one is a fish
—at least one is an invertebrate
—at least one is a saltwater species (the other two may be freshwater species)

3. At least one test with a saltwater alga or a chronic test with a saltwater vascular plant (see Section VIII). If plants are among the aquatic organisms most sensitive to the substance, tests with more than one species should be available.

4. At least one acceptable bioconcentration factor determined with an aquatic animal species, if a maximum permissible tissue concentration is available (see Section IX).

D. If all the requirements of the minimum data base are met, a criterion can usually be derived, except in special cases. For example, a criterion might not be possible if the acute-chronic ratios vary greatly with no apparent pattern. Also, if a criterion is to be related to a water quality characteristic, (see Sections V and VII), more data will be necessary.

Similarly, if the minimum data requirements are not satisfied, generally a criterion should not be derived, except in special cases. One such special case would be when less than the minimum amount of acute and chronic data are available, but the available data clearly indicate that the Final Residue Value would be substantially lower then either the Final Chronic Value or the Final Plant Value.

IV. Final Acute Value

A. Appropriate measures of the acute (short-term) toxicity of the substance to various species of aquatic animals are used to calculate the Final Acute Value. If acute values are available for fewer than twenty species, the Final Acute Value probably should be lower than the lowest value. On the other hand, if acute values are available for more than twenty species, the Final Acute Value probably should be higher than the lowest value, unless the most sensitive species is an important one. Although the procedure used to calculate the Final Acute Value has some limitations, it apparently is the best of the procedures currently available.

B. Acute toxicity tests should be conducted using procedures such as those described in:

ASTM Standard E 729–80, Practice for Conducting Acute Toxicity Tests with Fishes, Macroinvertebrates, and Amphibians. American Society for Testing and Materials, 1916 Race Street, Philadelphia, PA 19103.

ASTM Standard E 724–80, Practice for Conducting Static Acute Toxicity Tests with Larvae of Four Species of Bivalve Molluscs. American Society for Testing and Materials, 1916 Race Street, Philadelphia, PA 19103.

C. Results of acute tests in which food was added to the test solutions should not be used, because this may unnecessarily affect the results of the test.

D. Results of acute tests conducted with embryos should not be used (but see Section IV.E.2), because this is often an insensitive life stage.

E. Acute values should be based on endpoints and lengths of exposure appropriate to the life stage of the species tested. Therefore, only the following kinds of data on acute toxicity to aquatic animals should be used:

1. 48-hr EC50 values based on immobilization and 48-hr LC50 values for first-instar (less than 24 hours old) daphnids and other cladocerans, and second- or third-instar midge larvae.

2. 48- to 96-hr EC50 values based on incomplete shell development and 48- to 96-hr LC50 values for embryos and larvae of barnacles, bivalve molluscs (clams, mussels, oysters, and scallops), sea urchins, lobsters, crabs, shrimps, and abalones.

3. 96-hr EC50 values based on decreased shell deposition for oysters.

4. 96-hr EC50 values on immobilization or loss of equilibrium or both and 96-hr LC50 values for aquatic animals, except for cladocerans, midges, and animals whose behavior or physiology allows them to avoid

exposure to toxicant or for whom the acute adverse effect of the exposure cannot be adequately measured. Such freshwater and saltwater animals include air-breathing mollusca, unionid clams, operculate snails, and bivalve molluscs, except for some species that cannot "close up" and thus prevent exposure to toxicant, such as the bay scallop (*Argopecten irradians*).

F. For the use of LC50 or EC50 values for durations shorter and longer than those listed above, see Section X.

G. If the acute toxicity of the substance to aquatic animals has been shown to be related to a water quality characteristic such as hardness for freshwater organisms or salinity for saltwater organisms, a Final Acute Equation should be derived based on that water quality characteristic. Go to Section V.

H. If the acute toxicity of the substance has not been adequately shown to be related to a water quality characteristic, for each species for which at least one acute value is available, calculate the geometric mean of the results of all flow-through tests in which the toxicant concentrations were measured. For a species for which no such result is available, calculate the geometric mean of all available acute values, i.e., results of flow-through tests in which the toxicant concentrations were not measured and results of static and renewal tests based on initial total toxicant concentrations.

Note.—The geometric mean of N numbers is obtained by taking the N^{th} root of the product of N numbers. Alternatively, the geometric mean can be calculated by adding the logarithms of the N numbers, dividing the sum by N, and taking the antilog of the quotient. The geometric mean of two numbers can also be calculated as the square foot of the product of the two numbers. The geometric mean of one number is that number. Either natural (base e) or common (base 10) logarithms can be used to calculate geometric means as long as they are used consistently within each set of data, i.e., the antilog used must match the logarithm used.

I. Count the number = N of species for which a species mean acute value is available.

J. Order the species mean acute values from low to high. Take the common logarithms of the N values (log mean values).

K. The intervals (cell widths) for the lower cumulative proportion calculations are 0.11 common log units apart, starting from the lowest log value. The value of 0.11 is an estimate of average precision and was calculated from replicate species acute values.

L. Starting with the lowest log mean value, separate the N values into intervals (or cells) calculated in Step IV. K.

M. Calculate cumulative proportions for each non-empty interval by summing the number of values in the present and all lower intervals and dividing by N. These calculations only need to be done for the first three non-empty intervals (or cells).

N. Calculate the arithmetic mean of the log mean values for each of the three intervals.

O. Using the two interval mean acute values and cumulative proportions closest to 0.05, linearly extrapolate or interpolate to the 0.05 log concentration. The Final Acute Value is the antilog of the 0.05 concentration.

In other words, where

Prop(1) and conc(1) are the cumulative proportion and mean log value for the lowest non-empty interval.

Prop(2) and conc(2) are the cumulative proportion and mean log value for the second lowest non-empty interval.

A = Slope of the cumulative proportions

B = The 0.05 log value

Then:

A = [0.05 − Prop(1)]/[Prop(2) − Prop(1)]

B = conc(1) + A [conc(2) − conc(1)]

Final Acute Value = 10^{B}

P. If for an important species, such as a recreationally or commercially important species, the geometric mean of the acute values from flow-through tests in which the toxicant concentrations were measured is lower than the Final Acute Value, then that geometric mean should be used as the Final Acute Value.

Q. Go to Section VI.

V. Final Acute Equation

A. When enough data are available to show that acute toxicity to two or more species is similarly affected by a water quality characteristic, this effect can be taken into account as described below. Pooled regression analysis should produce similar results, although data available for individual species would be weighted differently.

B. For each species for which comparable acute toxicity values are available at two or more different values of a water quality characteristic which apparently affects toxicity, perform a least squares regression of the natural logarithms of the acute toxicity values on the natural logarithms of the values of the water quality characteristic. (Natural logarithms [logarithms to the base e, denoted as ln] are used herein merely because they are easier to use on some hand calculators and computers than common logarithms [logarithms to the base 10]. Consistent use of either will produce the same result.) No transformation or a different transformation may be used if it fits the data better, but appropriate changes will be necessary throughout this section.

C. Determine whether or not each acute slope is meaningful, taking into account the range and number of values of the water quality characteristic tested. For example, a slope based on four data points may be of limited value if it is based only on data for a narrow range of values of the water quality characteristic. On the other hand, a slope based on only two data points may be meaningful if it is consistent with other information and if the two points cover a broad enough range of the water quality characteristic. If meaningful slopes are not available for at least two species or if the available slopes are not similar, return to Section IV. H., using the results of tests conducted under conditions and in water similar to those commonly used for toxicity tests with the species.

D. Calculate the mean acute slope (V) as the arithmetic average of all the meaningful acute slopes for individual species.

E. For each species calculate the geometric mean (W) of the acute toxicity values and the geometric mean (X) of the related values of the water quality characteristic.

F. For each species calculate the logarithmic intercept (Y) using the equation: Y = ln W − V(ln X).

G. For each species calculate the species mean acute intercept as the antilog of Y.

H. Obtain the Final Acute Intercept by using the procedure described in Section IV. I–O, except insert "Intercept" for "Value".

I. If for an important species, such as a recreationally or commercially important species, the intercept calculated only from results of flow-through tests in which the toxicant concentrations were measured is lower than the Final Acute Intercept, then that intercept should be used as the Final Acute Intercept.

J. The Final Acute Equation is written as $e^{(V[\ln(\text{water quality characteristic})]+\ln Z)}$, where V = mean acute slope and Z = Final Acute Intercept.

VI. Final Chronic Value

A. The Final Chronic Value can be calculated in the same manner as the Final Acute Value or by dividing the Final Acute Value by the Final Acute-Chronic Ratio, depending on the data available. In some cases it will not be possible to calculate a Final Chronic Value.

B. Use only the results of flow-through (except renewal is acceptable for daphnids) chronic tests in which the concentrations of toxicant in the test solutions were measured.

C. Do not use the results of any chronic test in which survival, growth, or reproduction among the controls was unacceptably low.

D. Chronic values should be based on endpoints and lengths of exposure appropriate to the species. Therefore, only the results of the following kinds of chronic toxicity tests should be used:

1. Life-cycle toxicity tests consisting of exposures of each of several groups of individuals of a species to a different concentration of the toxicant throughout a life cycle. To ensure that all life stages and life processes are exposed, the test should begin with embryos or newly hatched young less than 48 hours old (less than 24 hours old for daphnids), continue through maturation and reproduction, and with fish should end not less than 24 days (90 days for salmonids) after the hatching of the next generation. For fish, data should be obtained and analyzed on survival and growth of adults and young, maturation of males and females, embryos spawned per female, embryo viability (salmonids only) and hatchability. For daphnids, data should be obtained and analyzed on survival and young per female.

2. Partial life-cycle toxicity tests consisting of exposures of each of several groups of individuals of a species of fish to a different concentration of the toxicant through most portions of a life cycle. Partial life-cycle tests are conducted with fish species that require more than a year to reach sexual maturity, so that the test can be completed in less than 15 months, but still expose all major life stages to the toxicant. Exposure to the toxicant begins with immature juveniles at least 2 months prior to active gonad development, continues through maturation and reproduction, and ends not less than 24 days (90 days for salmonids) after the hatching of the next generation. Data should be obtained and analyzed on survival and growth of adults and young, maturation of males and females, embryos spawned per female, embryo viability (salmonids only) and hatchability.

3. Early-life-stage toxicity tests consisting of 28- to 32-days (60 days post-hatch for salmonids) exposures of the early life stages of a species of fish from shortly after fertilization through embryonic, larval, and early juvenile development. Data should be obtained and analyzed on survival and growth.

E. Do not use the results of an early-life-stage test if results of a life-cycle or partial life-cycle test with the same species are available.

F. A chronic value is obtained by calculating the geometric mean of the lower and upper chronic limits from a chronic test. A lower chronic limit is the highest tested concentration (1) in an acceptable chronic test, (2) which did not cause the occurrence (which was statistically significantly different from the control at $p = 0.05$) of a specified adverse effect, and (3) below which no tested concentration caused such an occurrence. An upper chronic limit is the lowest tested concentration (1) in an acceptable chronic test, (2) which did cause the occurrence (which was statistically significantly different from the control at $p = 0.05$) of a specified adverse effect and (3) above which all tested concentrations caused such an occurrence.

Note.—Various authors have used a variety of terms and definitions to interpret the results of chronic tests, so reported results should be reviewed carefully.

G. If the chronic toxicity of the substance to aquatic animals has been adequately shown to be related to a water quality characteristic such as hardness for freshwater organisms or salinity for saltwater organisms, a Final Chronic Equation should be derived based on that water quality characteristic. Go to Section VII.

H. If chronic values are available for eight species as described in Section III. B.1 or III. C.1, a species mean chronic value should be calculated for each species for which at least one chronic value is available by calculating the geometric mean of all the chronic values for the species. The Final Chronic Value should then be obtained using the procedures described in Section IV. I–O. Then go to Section VI. M.

I. For each chronic value for which at least one appropriate acute value is available, calculate an acute-chronic ratio, using for the numerator the arithmetic average of the results of all standard flow-through acute tests in which the concentrations were measured and which are from the same study as the chronic test. If such an acute test is not available, use for the numerator the results of a standard acute test performed at the same laboratory with the same species, toxicant and dilution water. If no such acute test is available, use the species mean acute value for the numerator.

Note.—If the acute toxicity or chronic toxicity or both of the substance have been adequately shown to be related to a water quality characteristic, the numerator and the denominator must be based on tests performed in the same water.

J. For each species, calcuate the species mean acute-chronic ratio as the geometric mean of all the acute-chronic ratios available for that species.

K. For some substances the species mean acute-chronic ratio seems to be the same for all species, but for other substances the ratio seems to increase as the species mean acute value increases. Thus the Final Acute-Chronic Ratio can be obtained in two ways, depending on the data available.

1. If no major trend is apparent and the acute-chronic ratios for a number of species are within a factor of ten, the final Acute-Chronic Ratio should be calculated as the geometric mean of all the species mean acute-chronic ratios available for both freshwater and saltwater species.

2. If the species mean acute-chronic ratio seems to increase as the species mean acute value increases, the value of the acute-chronic ratio for species whose acute values are close to the Final Acute Value should be chosen as the Final Acute-Chronic Ratio.

L. Calculate the Final Chronic Value by dividing the Final Acute Value by the Final Acute-Chronic Ratio.

M. If the species mean chronic value of an important species, such as a commercially or recreationally important species, is lower than the Final Chronic Value, then that species mean chronic value should be used as the Final Chronic Value.

N. Go to Section VIII.

VII. Final Chronic Equation

A. For each species for which comparable chronic toxicity values are available at two or more different values of a water quality characteristic which apparently affects chronic toxicity, perform a least squares regression of the natural logarithms of the chronic toxicity values on the natural logarithms of the water quality characteristic values. No transformation or a different transformation may be used if it fits the data better, but appropriate changes will be necessary throughout this section. It is probably preferable, but not necessary, to use the same transformation that was used with the acute values in Section V.

B. Determine whether or not each chronic slope is meaningful, taking into account the range and number of values of the water quality characteristic tested. For example, a slope based on four data points may be of limited value if it is based only on data for a narrow range of values of the water quality characteristic. On the other hand, a slope based on only two data points may be meaningful if it is consistent with other information and if the two points cover a broad enough range of the water quality characteristic. If a meaningful chronic slope is not available for at least one species, return to Section VI. H.

C. Calculate the mean chronic slope (L) as the arithmetic average of all the meaningful chronic slopes for individual species.

D. For each species calculate the geometric mean (M) of the toxicity values and the geometric mean (P) of the related values of the water quality characteristic.

E. For each species calculate the logarithmic intercept (Q) using the equation: $Q = \ln M - L(\ln P)$.

F. For each species calculate a species mean chronic intercept as the antilog of Q.

G. Obtain the Final Chronic Intercept by using the procedure described in Section IV. I–O, except insert "Intercept" for "Value".

H. If the species mean chronic intercept of an important species, such as a commercially or recreationally important species, is lower than the Final Chronic Intercept, then that species mean chronic intercept should be used as the Final Chronic Intercept.

I. The Final Chronic Equation is written as $e^{(L \ln(\text{Water quality characteristic}) + \ln R)}$, where L = mean chronic slope and R = Final Chronic Intercept.

VIII. Final Plant Value

A. Appropriate measures of the toxicity of the substance to aquatic plants are used to compare the relative sensitivities of aquatic plants and animals.

B. A value is a concentration which decreased growth (as measured by dry weight, chlorophyll, etc.) in a 96-hr or longer test with an alga or in a chronic test with an aquatic vascular plant.

C. Obtain the Final Plant Value by selecting the lowest plant value from a test in which the toxicant concentrations were measured.

IX. Final Residue Value

A. The Final Residue Value is derived in order to (1) prevent commercially or recreationally important aquatic organisms from exceeding relevant FDA action levels and (2) protect wildlife, including fishes and birds, that eat aquatic organisms from demonstrated adverse effects. A residue value is calculated by dividing a maximum permissible tissue concentration by an appropriate bioconcentration factor (BCF), where the BCF is the quotient of the concentration of a substance in all or part of an aquatic organism divided by the concentration in water to which the organism has been exposed. A maximum permissible tissue concentration is either (1) an action level from the FDA Administrative Guidelines Manual for fish oil or for the edible portion of fish or shellfish, or (2) a maximum acceptable dietary intake based on observations on survival, growth or reproduction in a chronic wildlife feeding study. If no maximum permissible tissue concentration is available, go to Section X because no Final Residue Value can be derived.

B. 1. A BCF determined in a laboratory test should be used only if it was calculated based on measured concentrations of the substance in the test solution and was based on an exposure that continued until either steady-state or 28-days was reached. Steady-state is reached when the BCF does not change significantly over a period of time, such as two days or 16 percent of the length of the exposure, whichever is longer. If a steady-state BCF is not available for a species, the available BCF for the longest exposure over 28 days should be used for that species.

2. A BCF from a field exposure should be used only when it is known that the concentration of the substance was reasonably constant for a long enough period of time over the range of territory inhabited by the organisms.

3. If BCF values from field exposures are consistently lower or higher than those from laboratory exposures, then only those values from field exposures should be used if possible.

4. A BCF should be calculated based on the concentration of the substance and its metabolites, which are structurally similar and are not much more soluble in water than the parent compound, in appropriate tissue and should be corrected for the concentration in the organisms at the beginning of the test.

5. A BCF value obtained from a laboratory or field exposure that caused an observable adverse effect on the test organism may be used only if it is similar to that obtained with unaffected organisms at lower concentrations in the same test.

6. Whenever a BCF is determined for a lipid-soluble substance, the percent lipids should also be determined in the tissue for which the BCF was calculated.

C. A BCF calculated using dry tissue weights must be converted to a wet tissue weight basis by multiplying the dry weight BCF value by 0.1 for plankton and by 0.2 for individual species of fishes and invertebrates.

Note.—The values of 0.2 and 0.1 were derived from data published in:

McDiffett, W. F., 1970. Ecology 51:975–988.

Ruttner, F., 1963. Fundamentals of Limnology. 3rd ed. Trans. by D. G. Frey and F. E. J. Fry. Univ. of Toronto Press, Toronto.

Some additional values can be found in:

Sculthorpe, C. D., 1967. The Biology of Aquatic Vascular Plants. Arnold Publishing Ltd., London.

D. If enough pertinent data exist, several residue values can be calculated by dividing maximum permissible tissue concentrations by appropriate BCF values.

1. For each available maximum acceptable dietary intake derived from a chronic feeding study with wildlife, including birds and aquatic organisms, the appropriate BCF is based on the whole body of aquatic species which constitute or represent a major portion of the diet of the tested wildlife species.

2. For an FDA action level, the appropriate BCF is the highest geometric mean species BCF for the edible portion (muscle for decapods, muscle with or without skin for fishes, adductor muscle for scallops and total living tissue for other bivalve molluscs) of a consumed species. The highest species BCF is used because FDA action levels are applied on a species-by-species basis.

E. For lipid-soluble substances, it may be possible to calculate additional residue values. Because steady-state BCF values for a lipid-soluble chemical seem to be proportional to percent lipids from one tissue to another and from one species to another, extrapolations can be made from tested tissues or species to untested tissues or species on the basis of percent lipids.

1. For each BCF for which the percent lipids is known for the same tissue for which the BCF was measured, the BCF should be normalized to a one percent lipid basis by dividing the BCF by the percent lipids. This adjustment to a one percent lipid basis makes all the measured BCF values comparable regardless of the species or tissue for which the BCF was measured.

2. Calculate the geometric mean normalized BCF. Data for both saltwater and freshwater species can be used to determine the mean normalized BCF, because the normalized BCF seems to be about the same for both kinds of organisms.

3. Residue values can then be calculated by dividing the maximum permissible tissue concentrations by the mean normalized BCF and by a percent lipids value appropriate to the maximum permissible tissue concentration, *i.e.*,

$$\text{Residue Value} = \frac{\text{(maximum permissible tissue concentration)}}{\text{(mean normalized BCF)(appropriate percent lipids)}}$$

a. For an FDA action level for fish oil, the appropriate percent lipids value is 100.

b. For an FDA action level for fish, the appropriate percent lipids value is 15 for freshwater criteria and 16 for saltwater criteria because FDA action levels are applied on a species-by-species basis to commonly consumed species. The edible portion of the freshwater lake trout averages about 15 percent lipids, and the edible portion of the saltwater Atlantic herring averages about 16 percent lipids (Sidwell, V. D., et al. 1974 Composition of the Edible Portion of Raw (Fresh or Frozen) Crustaceans, Finfish, and Mollusks. I. Protein, Fat, Moisture, Ash, Carbohydrate, Energy Value, and Cholesterol. Marine Fisheries Review 36:21–35).

c. For a maximum acceptable dietary intake derived from a chronic feeding study with wildlife, the appropriate percent lipids is the percent lipids of an aquatic species or group of aquatic species which constitute a major portion of the diet of the wildlife species.

F. The Final Residue Value is obtained by selecting the lowest of the available residue values. It should be noted that in many cases the Final Residue Value will not be low enough. For example, a residue value calculated from an FDA action level would result in an average concentration in the edible portion of a fatty species that is at the action level. On the average half of the individuals of the species would have concentrations above the FDA action level. Also, the results of many chronic feeding studies are concentrations that cause adverse effects.

X. Other Data

Pertinent information that could not be used in earlier sections may be available concerning adverse effects on aquatic organisms and their uses. The most important of these are data on flavor impairment, reduction in survival, growth, or reproduction, or any other adverse effect that has been shown to be biologically significant. Especially important are data for species for which no other data are available. Data from behavioral, micorcosm, field, and physiological studies may also be available.

XI. Criterion

A. The criterion consists of two concentrations, one that should not be exceeded on the average in a 24-hour period and one that should not be exceeded at any time during the 24-hour period. This two-number criterion is intended to identify water quality conditions that should protect aquatic life and its uses from acute and chronic adverse effects of both cumulative and noncumulative substances without being as restrictive as a one-number criterion would have to be to provide the same degree of protection.

B. The maximum concentration is the Final Acute Value or is obtained from the Final Acute Equation.

C. The 24-hour average concentration is obtained from the Final Chronic Value, the Final Plant Value, and the Final Residue Value by selecting the lowest available value, unless other data (see Section X) from tests in which the toxicant concentrations were measured show that a lower value should be used. If toxicity is related to a water quality characteristic, the 24-hour average concentration is obtained from the Final Chronic Equation, the Final Plant Value, and the Final Residue Value by selecting the one that results in the lowest concentrations in the normal range of the water quality characteristic, unless other data (see Section X) from tests in which the toxicant concentrations were measured show that a lower value should be used.

D. The criterion is (the 24-hour average concentration) as a 24-hour average and the concentration should not exceed (the maximum concentration) at any time.

XII. Review

A. On the basis of all available pertinent laboratory and field information, determine if the criterion is consistent with sound scientific evidence. If it is not, another criterion, either higher or lower, should be derived using appropriate modifications of the Guidelines.

These Guidelines were written by Charles E. Stephan, Donald I. Mount, David J. Hansen, John H. Gentile, Gary A. Chapman and William A. Brungs of the U.S.E.P.A. Environmental Research Laboratories in Corvallis, Oregon, Duluth, Minnesota, Gulf Breeze, Florida, and Narragansett, Rhode Island. Numerous other people, many of whom do not work for U.S.E.P.A., provided assistance and suggestions.

Appendix C—Guidelines and Methodology Used in the Preparation of Health Effect Assessment Chapters of the Consent Decree Water Criteria Documents

I. Objective

The objective of the health effect assessment chapters of the ambient water criteria documents is to estimate ambient water concentrations which do not represent a significant risk to the public. These assessments should constitute a review of all relevant information on individual chemicals or chemical classes in order to derive criteria that represent, in the case of suspect or proven carcinogens, various levels of incremental cancer risk, or, in the case of other pollutants, estimates of no-effect levels.

Ideally, ambient water quality criteria should represent levels for compounds in ambient water that do not pose a hazard to the human population. However, in any realistic assessment of human health hazard, a fundamental distinction must be made between absolute safety and the recognition of some risk. Criteria for absolute safety would have to be based on detailed knowledge of dose-response relationships in humans, including all sources of chemical exposure, the types of toxic effects elicited, the existence of thresholds for the toxic effects, the significance of toxicant interactions, and the variances of sensitivities and exposure levels within the human population. In practice, such absolute criteria cannot be established because of deficiencies in both the available data and the means of interpreting this information. Consequently, the individual human health effects chapters propose criteria which minimize or specify the potential risk of adverse human effects due to substances in ambient water. Potential social or economic costs and benefits are not considered in the formulation of the criteria.

II. Types of Criteria

Ambient water quality criteria are based on three types of biological endpoints: carcinogenicity, toxicity (i.e., all adverse effects other than cancer), and organoleptic effects.

For the purpose of deriving ambient water quality criteria, carcinogenicity is regarded as a non-threshold phenomenon. Using this assumption, "safe" or "no effect" levels for carcinogens cannot be established because even extremely small doses must be assumed to elicit a finite increase in the incidence of the response. Consequently, water quality criteria for carcinogens are presented as a range of pollutant concentrations associated with corresponding incremental risks.

For compounds which do not manifest any apparent carcinogenic effect, the threshold assumption is used in deriving a criterion. This assumption is based on the premise that a physiological reserve capacity exists within the organism which is thought to be depleted before clinical disease ensues. Alternatively, it may be assumed that the rate of damage will be insignificant over the life span of the organism. Thus, ambient water quality criteria are derived for non-carcinogenic chemicals, and presumably result in no observable-adverse-effect levels (NOAELs) in the exposed human population.

In some instances, criteria are based on organoleptic characteristics, i.e., thresholds for taste or odor. Such criteria are established when insufficient information is available on toxicologic effects or when the estimate of the level of the pollutant in ambient water based on organoleptic effects is lower than the level calculated from toxicologic data. It should be recognized that criteria based solely on organoleptic effects do not necessarily represent approximations of acceptable risk levels for human health.

Several ambient water quality criteria documents deal with classes of compounds which include chemicals exhibiting varying degrees of structural similarity. Because prediction of biological effects based solely on structural parameters is difficult, the derivation of compound-specific criteria is preferable to a class criterion. A compound-specific criterion is defined as a level derived from data on each individual subject compound that does not represent a significant risk to the public. For some chemical classes, however, a compound-specific criterion cannot be derived for each member of a class. In such instances, it is sometimes justifiable to derive a class criterion in which available data on one member of a class may be used to estimate criteria for other chemicals of the class because a sufficient data base is not available for those compounds.

For some chemicals and chemical classes, the data base was judged to be insufficient for the derivation of a criterion. In those cases, deficiencies in the available information are detailed.

III. Approach

The human health effects chapters attempt to summarize all information on the individual chemicals or classes of chemicals which might be useful in the risk assessment process to develop water quality criteria. Although primary emphasis is placed on identifying epidemiologic and toxicologic data, these assessments typically contain discussions on four topics: existing levels of human exposure, pharmacokinetics, toxic effects, and criterion formulation.

For all documents, an attempt is made to include the known relevant information. Review articles and reports are often used in the process of data evaluation and synthesis. Scientific judgment is exercised in the review and evaluation of the data in each document and in the identification of the adverse effects against which protective criteria are sought. In addition, each of these documents is reviewed by a peer committee of scientists familiar with the specific compound(s). These work groups evaluate the quality of the available data, the completeness of the data summary, and the validity of the derived criterion.

In the analysis and organization of the data, an attempt is made to be consistent with respect to the format and the application of acceptable scientific principles. Evaluation procedures used in the hazard assessment process follow the principles outlined by the National Academy of Sciences in *Drinking Water and Health* (1977) and the guidelines of the Carcinogen Assessment Group of the U.S. EPA.

A. Exposure

The exposure section of the health effects chapters reviews known information on current levels of human exposure to the individual pollutant from all sources. Much of the data was obtained from monitoring studies of air, water, food, soil, and human or animal tissue residues. The major purpose of this section is to provide background information on the contribution of water exposure relative to all other sources. Consequently, the exposure section includes subsections reviewing different routes of exposure including water and food ingestion, inhalation, and dermal contact.

Information on exposure can be valuable in developing and assessing a water quality criterion. In these documents exposure from consumption of contaminated water and contaminated fish and shellfish products is used in criterion formulation. Data for all modes of exposure are useful in relating total intake to the expected contribution from contaminated water, fish, and shellfish. In addition, information for all routes of exposure, not limited to drinking water and fish and shellfish ingestion, can be used to justify or assess the feasibility of the formulation of criteria for ambient water.

The use of fish consumption as an exposure factor requires the quantitation of pollutant residues in the edible portions of the ingested species. Accordingly, bioconcentration factors (BCFs) are used to relate pollutant residues in aquatic organisms to the pollutant concentration in the ambient waters in which they reside.

To estimate the average per capita intake of a pollutant due to consumption of contaminated fish and shellfish the results of a diet survey were analyzed to calculate the average consumption of freshwater and estuarine fish and shellfish (U.S. EPA, 1980). A species is considered to be a consumed freshwater or estuarine fish and shellfish species if at some stage in its life cycle, it is harvested from fresh or estuarine water for human consumption in significant quantities (Stephan, 1980).

Three different procedures are used to estimate the weighted average BCF depending upon the lipid solubility of the chemical and the availability of bioconcentration data.

For lipid-soluble compounds, the average BCF is calculated from the weighted average percent lipids in the edible portions of consumed freshwater and estuarine fish and shellfish which was calculated from data on consumption of each species and its corresponding percent lipids to be 3.0 percent (Stephan, 1980). Because the steady-state BCFs for lipid-soluble compounds are proportional to percent lipids, bioconcentration factors for fish and shellfish can be adjusted to the average percent lipids for aquatic organisms consumed by Americans. For many lipid-soluble pollutants, there exists at least one BCF for which the percent lipid value was measured for the tissues for which the BCF is determined.

With 3.0 percent as the weighted average percent lipids for freshwater and estuarine fish and shellfish in the average diet, a BCF, and a corresponding percent lipid value, the weighted average bioconcentration factor can be calculated.

Example:

Weighted average percent lipids for average diet = 3.0 percent

Measured BCF of 17 for trichloroethylene with bluegills at 4.8 percent lipids

Weighted average BCF for average diet equals

$$17 \times \frac{3.0\%}{4.8\%} = 10.6$$

As an estimate, 10.6 is used for the BCF.

In those cases where an appropriate bioconcentration factor is not available, the equation "$\text{Log BCF} = (0.85 \text{ Log P}) - 0.70$" can be used (Veith, et al. 1979) to estimate the BCF for aquatic organisms containing about 7.6 percent lipids (Veith, 1980) from the octanol/water partition coefficient P. An adjustment for percent lipids in the average diet versus 7.6 percent is made in order to derive the weighted average bioconcentration factor.

For non-lipid-soluble compounds, the available BCFs for the edible portion of consumed freshwater and estuarine fish and shellfish are weighted according to consumption factors to determine a weighted BCF representative of the average diet.

B. Pharmacokinetics

This section summarizes the available information on the absorption, distribution, metabolism, and elimination of the compound(s) in humans and experimental mammals. Conceptually, such information is useful in validation of inter- and intraspecies extrapolations, and in characterizing the modes of toxic action. Sufficient information on absorption and excretion in animals, together with a knowledge of ambient concentrations in water, food, and air, could be useful in estimating body burdens of chemicals in the human population. Distribution data which suggest target organs or tissues are desirable for interspecies comparison techniques. In terms of the derivation of criteria, pharmacokinetic data are essential to estimate equivalent oral doses based on data from inhalation or other routes of exposure.

C. Effects

This section summarizes information on biological effects in both humans and experimental mammals resulting in: acute, subacute, and chronic toxicity, synergism and/or antagonism, teratogenicity, mutagenicity, or carcinogenicity.

The major goal of this section is to survey the suitability of the data for use in assessment of hazard and to determine which biological end-point, i.e., non-threshold, threshold, or organoleptic, should be selected for use in criterion formulation.

Because this section attempts to assess potential human health effects, data on documented human effects are thoroughly evaluated. However, several factors inherent in human epidemiological studies usually preclude the use of such data in generating water quality criteria. These problems, as summarized by the National Academy of Sciences (NAS, 1977) are as follows:

1. Epidemiology cannot tell what effects a material will have until after humans have been exposed. One must not conduct what might be hazardous experiments on man.
2. If exposure has been ubiquitous, it may be impossible to assess the effects of a material, because there is no unexposed control group. Statistics of morbidity obtained before use of a new material can sometimes be useful, but when latent periods are variable and times of introduction and removal of materials overlap, historical data on chronic effects are usually unsatisfactory.
3. It is usually difficult to determine doses in human exposures.
4. Usually, it is hard to identify small changes in common effects, which may nonetheless be important if the population is large.
5. Interactions in a "nature-designed" experiment usually cannot be controlled.

Although these problems often prevent the use of epidemiological data in quantitative risk assessments, qualitative similarities or differences between documented effects in humans and observed effects in experimental mammals are extremely useful in testing the validity of animal-to-man extrapolations. Consequently, in each case, an attempt is made to identify and utilize both epidemiologic and animal dose-response data. Criteria derived from such a confirmed data base are considered to be reliable.

The decision to establish a criterion based on a non-threshold model is made after evaluating all available information on carcinogenicity and supportive information on mutagenicity. The approach and conditions for the qualitative decision of carcinogenicity are outlined in the U.S. EPA Interim Cancer Guidelines (41 FR 21402), in a report by Albert, et al. (1977), and in the Interagency Regulatory Liaison Group (IRLG) guidelines on carcinogenic risks (IRLG, 1979). It is assumed that a substance which induces a statistically significant carcinogenic response in animals has the capacity to cause cancer in humans. A chemical which has not induced a significant cancer response in humans or experimental animals is not identified as a carcinogen, even though its metabolites or close structural analogues might induce a carcinogenic response or it was shown to be mutagenic in an *in vitro* system.

It is recognized that some potential human carcinogens may not be identified by the guidelines given above. For example, compounds for which there is plausible but weak qualitative evidence of carcinogenicity in experimental animal systems (such as data from mouse skin painting or strain A mouse pulmonary adenoma) would be included in this category. The derivation of a criterion for human consumption from these studies in not valid, regardless of the qualitative outcome. In addition, there are certain compounds (e.g., nickel and beryllium) which were shown to be carcinogenic in humans after inhalation exposure by chemical form, but have induced thus far no response in animals or humans via ingesting their soluble salts. Nevertheless, a non-threshold criterion is developed for beryllium because tumors have been produced in animals at a site removed from the site of administration; in contrast, a threshold criterion is recommended for nickel because there is no evidence of tumors at sites distant resulting from administration of nickel solutions by either ingestion or injection.

For those compounds which were not reported to induce carcinogenic effects or for those compounds for which carcinogenic data are lacking or insufficient, an attempt is made to estimate a no-effect level. In many respects, the hazard evaluation from these studies is similar to that of bioassays for carcinogenicity. In order to more closely approximate conditions of human exposure, preference is given to chronic studies involving oral exposures in water or diet over a significant portion of the animal life span. Greatest confidence is placed in those studies which demonstrate dose-related adverse effects as well as no-effect levels.

There is considerable variability in the biological endpoints used to define a no-effect level. They may range from gross effects, such as mortality, to more subtle biochemical, physiological, or pathological changes. Teratogenicity, reproductive impairment, and behavioral effects are significant toxic consequences of environmental contamination. In instances where carcinogenic or other chronic effects occur at exposure levels below those causing teratogenicity, reproductive impairment, or behavioral effects, the former are used in deriving the criterion. For most of the compounds evaluated thus far, teratogenicity and reproductive impairment occur at doses near maximum tolerated levels with dose administration schedules well above estimated environmental exposure levels. Moreover, information on behavioral effects, which could be of significance, is not available for most of the compounds under study. Consequently, most NOAELs derived from chronic studies are based either on gross toxic effects or on effects directly related to functional impairment or defined pathological lesions.

For compounds on which adequate chronic toxicity studies are not available, studies on acute and subacute toxicity assume greater significance. Acute toxicity studies usually involve single exposures at lethal or near lethal doses. Subacute studies often involve exposures exceeding 10 percent of the life span of the test organism, e.g., 90 days for the rat with an average life span of 30 months. Such studies are useful in establishing the nature of the compound's toxic effects and other parameters of compound toxicity, such as target organ effects, metabolic behavior, physiological/biochemical effects, and patterns of retention and tissue distribution. The utility of acute and subacute studies in deriving environmentally meaningful NOELs is uncertain, although McNamara (1976) has developed application factors for such derivations.

In some cases where adequate data are not available from studies utilizing oral routes of administration, no-effect levels for oral exposures may be estimated from dermal or inhalation studies. Such estimates involve approximations of the total dose administered based on assumptions about breathing rates and/or magnitude of absorption.

D. Criterion Rationale

This section reviews existing standards for the chemical(s), summarizes data on current levels of human exposure, attempts to identify special groups at risk, and defines the basis for the recommended criterion.

Information on existing standards is included primarily for comparison with the proposed water quality criteria. Some of the present standards, such as those recommended by the Occupational Safety and Health Administration (OSHA) or the American Conference of Governmental Industrial Hygienists (ACGIH), are based on toxicologic data but are intended as acceptable levels for occupational rather than environmental exposure. Other levels, such as those recommended by the National Academy of Sciences in *Drinking Water and Health* (1977) or in the U.S. EPA Interim Primary Drinking Water Standards, are more closely related to proposed water quality criteria. Emphasis is placed on detailing the basis for the existing standards wherever possible.

Summaries of current levels of human exposure, presented in this section, specifically address the suitability of the data to derive water quality criteria. The identification of special groups at risk, either because of geographical or occupational differences in exposure or biological differences in susceptibility to the compound(s), focuses on the impact that these groups should have on the development of water quality criteria.

The basis for the recommended criteria section summarizes and qualifies all of the data used in developing the criteria.

IV. Guidelines for Criteria Derivation

The derivation of water quality criteria from laboratory animal toxicity data is essentially a two-step procedure. First, a total daily intake for humans must be estimated which establishes either a defined level of risk for non-threshold effects or a no-effect level for threshold effects. Secondly, assumptions must be made about the contribution of contaminated water and the consumption of fish/shellfish to the total daily intake of the chemical. These estimates are then used to establish the tolerable daily intake and consequently the water quality criterion.

A. Non-Threshold Effects

After the decision has been made that a compound has the potential for causing cancers in humans and that data exist which permit the derivation of a criterion, the water concentration which is estimated to cause a lifetime carcinogenic risk of 10^{-5} is determined. The lifetime carcinogenicity risk is the probability that a person would get cancer sometime in his or her life assuming continuous exposure to the compound. The water concentration is calculated by using the low-dose extrapolation procedure proposed by Crump (1980). This procedure is an improvement on the multistage low dose extrapolation procedure by Crump, et al. (1977).

The data used for quantitative estimates are of two types: (1) lifetime animal studies, and (2) human studies where excess cancer risk has been associated with exposure to the agent. In animal studies it is assumed, unless evidence exists to the contrary, that if a carcinogenic response occurs at the dose levels used in the study, then proportionately lower responses will also occur at all lower doses, with an incidence determined by the extrapolation model discussed below.

1. Choice of Model

There is no really solid scientific basis for any mathematical extrapolation model which relates carcinogen exposure to cancer risks at the extremely low levels of concentration that must be dealt with in evaluating the environmental hazards. For practical reasons, such low levels of risk cannot be measured directly either using animal experiments or epidemiologic studies. We must, therefore, depend on our current understanding of the mechanisms of carcinogenesis for guidance as to which risk model to use. At the present time, the dominant view of the carcinogenic process involves the concept that most agents which cause cancer also cause irreversible damage to DNA. This position is reflected by the fact that a very large proportion of agents which cause cancer are also mutagenic. There is reason to expect that the quantal type of biological response that is characteristic of mutagenesis is associated with a linear non-threshold dose-response relationship. Indeed, there is substantial evidence from mutagenesis studies with both ionizing radiation and with a wide variety of chemicals that this type of dose-response model is the appropriate one to use. This is particularly true at the lower end of the dose-response curve; at higher doses, there can be an upward curvature, probably reflecting the effects of multistage processes on the mutagenic response. The linear non-threshold dose-response relationship is also consistent with the relatively few epidemiological studies of cancer responses to specific agents that contain enough information to make the evaluation possible (e.g., radiation-induced leukemia, breast and thyroid cancer, skin cancer induced by arsenic in drinking water, and liver cancer induced by aflatoxin in the diet). There is also some evidence from animal experiments that is consistent with the linear non-threshold hypothesis (e.g., liver tumors induced in mice by 2-acetylaminofluorene in the large scale ED_{01} study at the National Center of Toxicological Research, and the initiation stage of the two-stage carcinogenesis model in the rat liver and the mouse skin).

Because it has the best, albeit limited, scientific basis of any of the current mathematical extrapolation models, the linear non-threshold model has been adopted as the primary basis for risk extrapolation to low levels of the dose-response relationship. The risk assessments made with this model should be regarded as conservative, representing the most plausible upper limit for the risk; i.e., the true risk is not likely to be higher than the estimate, but it could be smaller.

The mathematical formulation chosen to describe the linear, non-threshold dose-response relationship at low doses is the improved multistage model developed by Crump (1980). This model employs enough arbitrary constants to be able to fit almost any monotonically increasing dose-response data and it incorporates a procedure for estimating the largest possible linear slope (in the 95 percent confidence limit sense) at low extrapolated doses that is consistent with the data at all dose levels of the experiment. For this reason, it may be called a "linearized" multistage model.

2. Procedure of Low-Dose Extrapolation Based on Animal Carcinogenicity Data.

A. Description of the Extrapolation Model

Let P(d) represent the lifetime risk (probability) of cancer at dose d. The multistage model has the form

$$P(d) = 1 - \exp[-(q_0 + q_1d + q_2d^2 + \ldots + q_kd^k)]$$

where:

$q_i \geq 0$, and $i = 0, 1, 2, \ldots, k$

Equivalently,

$$A(d) = 1 - \exp[-(q_1d + q_2d^2 + \ldots + q_kd^k)]$$

where:

$$A(d) = \frac{P(d) - P(o)}{1 - P(o)},$$

is the extra risk over background rate at dose d.

The point estimate of the coefficients q_i, $i = 0, 1, 2, \ldots, k$, and consequently the extra risk function A(d) at any given dose d, is calculated by maximizing the likelihood function of the data.

The point estimate and the 95 percent upper confidence limit of the extra risk A(d) are calculated by using the computer program GLOBAL 79 developed by Crump and Watson (1979). Upper 95 percent confidence limits on the extra risk and lower 95 percent confidence limits on the dose producing a given risk are determined from a 95 percent upper confidence limit, q_1^*, on parameter q_1. Whenever $q_1 \neq 0$, at low doses extra risk A(d) has approximately the form $A(d) = q_1 \times d$. Therefore, $q_1 \times d$ is a 95 percent upper confidence limit on the extra risk and R/q_1^* is a 95 percent lower confidence limit on the dose producing an extra risk of R. Let L_0 be the maximum value of the log-likelihood function. The upper limit q_1^* is calculated buy increasing q_1 to a value q_1^* such that when the log-likelihood is again maximized subject to this fixed value q_1^* for the linear coefficient, the resulting maximum value of the log-likelihood L_1 satisfies the equation $2(L_0 - L_1) = 2.70654$ where 2.70554 is the cumulative 90 percent point of the chi-square distribution with one degree of freedom, which corresponds to a 95 percent upper limit (one-sided). This approach of computing the upper confidence limit for the extra risk A(d) is an improvement on the Crump, et al. (1977) model. The upper confidence limit for the extra risk calculated at low doses is always linear. This is conceptually consistent with the linear nonthreshold concept discussed earlier. The slope q_1^* is taken as an upper bound of the potency of the chemical in inducing cancer at low doses.

In fitting the dose-response model, the number of terms in the polynomial g is chosen equal to (h−1), where h is the number of dose groups in the experiment, including the control group.

Whenever the multistage model does not fit the data sufficiently, data at the highest dose is deleted and the model is refitted to the rest of the data. This is continued until an acceptable fit to the data is obtained. To determine whether or not a fit is acceptable, the chi-square statistic:

$$\chi^2 = \sum_{i=1}^{h} \frac{(X_i - N_iP_i)^2}{N_iP_i(1 - P_i)}$$

is calculated, where N_i is the number of animals in the i^{th} dose group, X_i is the number of animals in the i^{th} dose group with a tumor response, P_i is the probability of a response in the i^{th} dose group estimated by fitting the multistage model to the data, and h is the number of remaining groups.

The fit is determined to be unacceptable whenever chi-square (X^2) is larger than the cumulative 99 percent point of the chi-square distribution with f degrees of freedom, where f equals the number of dose groups minus the number of non-zero multistage coefficients.

3. Selection and Form of Data used to Estimate Parameters in the Extrapolation Model.

For some chemicals, several studies in different animal species, strains, and sexes each conducted at several doses and different routes of exposure are available. A choice must be made as to which of the data sets from several studies are to be used in the model. It is also necessary to correct for metabolism differences between species and for differences in absorption via different routes of administration. The procedures, listed below, used in evaluating these data are consistent with the estimate of a maximum-likely-risk.

a. The tumor incidence data are separated according to organ sites or tumor types. The set data (i.e., dose and tumor incidence) used in the model is set where the incidence is statistically significantly higher than the control for at least one test dose level and/or where the tumor incidence rate shows a statistically significant trend with respect to dose level. The data set which gives the highest estimate of lifetime carcinogenic risk q_1^* is selected in most cases. However, efforts are made to exclude data sets which produce spuriously high risk estimates because of a small number of animals. That is, if two sets of data show a similar dose-response relationship and one has a very small sample size, the set of data which has the larger sample size is selected for calculating the carcinogenic potency.

b. If there are two or more data sets of comparable size which are identical with respect to species, strain, sex, and tumor sites, the geometric mean of q_1^*, estimated from each of these data sets is used for risk assessment. The geometric mean of numbers $A_1, A_2, \ldots, A_m$ is defined as $(A_1 \times A_2 \times \ldots \times A_m)^{1/m}$

c. If sufficient data exist for two or more significant tumor sites in the same study, the number of animals with at least one of the specific tumor sites under consideration is used as incidence data in the model.

d. Following the suggestion of Mantel and Schneiderman (1975), we assume that mg/surface area/day is an equivalent dose between species. Since to a close approximation the surface area is proportional to the $2/3$rds power of the weight as would be the case for a perfect sphere, the exposure in mg/$2/3$rds power of the body weight/day is similarly considered to be an equivalent exposure. In an animal experiment, this equivalent dose is computed in the following manner:

Let:

L_e = duration of experiment
l_e = duration of exposure
m = average dose per day in mg during administration of the agent (i.e., during l_e)
W = average weight of the experimental animal.

Then, the lifetime average exposure is

$$d = \frac{l_e \times m}{L_e \times W^{2/3}}$$

Often exposures are not given in units of mg/day, and it becomes necessary to convert the given exposures into mg/day. For example, in most feeding studies, exposure is expressed as ppm in the diet. In this case the exposure (mg/day) is derived by: m = ppm × F × r where ppm is parts per million of the carcinogenic agent in the diet, F is the weight of the food consumed per day in kgms, and r is the absorption fraction.

In the absence of any data to the contrary, r is assumed to be one. For a uniform diet the weight of the food consumed is proportional to the calories required, which, in turn, is proportional to the surface area or the ⅔rds power of the weight, so that: $m \propto ppm \times W^{2/3} \times r$ or

$$\frac{m}{rW^{2/3}} \propto ppm$$

As a result, ppm in the diet is often assumed to be an equivalent exposure between species. However, we feel that this is not justified since the calories/kg of food is significantly different in the diet of man vs. laboratory animals, primarily due to moisture content differences. Instead, we use an empirically derived food factor, $f = F/W$, which is the fraction of a species body weight that is consumed per day as food. We use the rates given below.

Species	W	f
Man	70	0.028
Rat	0.35	0.05
Mice	0.03	0.13

Thus, when the exposure is given as a certain dietary concentration in ppm, the exposure in mg/$W^{2/3}$ is

$$\frac{m}{r \times W^{2/3}} = \frac{ppm \times F}{W^{2/3}} =$$

$$\frac{ppm \times f \times W}{W^{2/3}} = ppm \times f \times W^{1/3}$$

When exposure is given in terms of $mg/kg/day = m/Wr = s$ the conversion is simply:

$$\frac{m}{rW^{2/3}} = s \times W^{1/3}$$

When exposure is via inhalation, the calculation of dose can be considered for two cases where (1) the carcinogenic agent is either a completely water-soluble gas or an aerosol and is absorbed proportionally to the amount of air breathed in, and (2) where the carcinogen is a poorly water-soluble gas which reaches an equilibrium between the air breathed and the body compartments. After equilibrium is reached, the rate of absorption of these agents is expected to be proportional to metabolic rate, which in turn is proportional to the rate of oxygen consumption, which in turn is a function of surface area.

Case 1

Agents that are in the form of particulate matter or virtually completely absorbed gases such as SO_2 can reasonably be expected to be absorbed proportional to the breathing rate. In this case the exposure in mg/day may be expressed as: $m = I \times v \times r$ where I is inhalation rate per day in m^3, v is mg/m^3 of the agent in air, and r is the absorption fraction.

The inhalation rates, I, for various species can be calculated from the observation (FASEB, 1974) that 25 gm mice breathe 34.5 liters/day and 113 gm rats breathe 105 liters/day. For mice and rats of other weights, W, (expressed in kg), the surface area proportionality can be used to determine breathing rates (in m^3/day) as follows:

For mice, $I = 0.0345 (W/0.025)^{2/3} m^3/day$

For rats, $I = 0.105 (W/0.113)^{2/3} m^3/day$

For humans, the values of 20 m^3/day[*] is adopted as a standard breathing rate (ICRP, 1977).

The equivalent exposure in mg/$W^{2/3}$ for these agents can be derived from the air intake data in a way analogous to the food intake data. The empirical factors for the air intake per kg per day, $i = I/W$ based upon the previously stated relationships, are as tabulated below:

Species	W	i=I/W
Man	70	0.29
Rat	0.35	0.64
Mice	0.03	1.3

Therefore, for particulates or completely absorbed gases, the equivalent exposure in mg/$W^{2/3}$ is:

$$\frac{m}{W^{2/3}} = \frac{Ivr}{W^{2/3}} = \frac{iWvr}{W^{2/3}} = iW^{1/3}\,vr$$

In the absence of empirical data or a sound theoretical argument to the contrary, the fraction absorbed, r, is assumed to be the same for all species.

Case 2

The dose in mg/day of partially soluble vapors is proportional to the O_2 consumption which in turn is proportional to $W^{2/3}$ and to the solubility of gas in body fluids, which can be expressed as an absorption coefficient r for the gas. Therefore, when expressing the O_2 consumption as $O_2 = k W^{2/3}$, where k is a constant independent of species, it follows that $m = k W^{2/3} \times v \times r$ or

$$d = \frac{m}{W^{2/3}} = kvr$$

As with Case 1, in the absence of experimental information or a sound theoretical argument to the contrary, the absorption fraction, r, is assumed to be the same for all species. Therefore, for these substances a certain concentration in ppm or μ/m^3 in experimental animals is equivalent to the same concentration in humans. This is supported by the observation that the minimum alveolar concentration, necessary to produce a given "stage" of anesthesia, is similar in man and animals (Dripps, et al. 1977). When the animals were exposed via the oral route and human exposure is via inhalation or vice-versa, the assumption is made, unless there is pharmacokinetic evidence to the contrary, that absorption is equal by either exposure route.

e. If the duration of experiment (L_e) is less than the natural life span of the test animal (L), the slope q_1^*, or more generally the exponent g(d), is increased by multiplying a factor $(L/L_e)^3$. We assume that if the average dose, d, is continued, the age specific rate of cancer will continue to increase as a constant function of the background rate. The age specific rates for humans increase at least by the 2nd power of the age and often by a considerably higher power, as demonstrated by Doll (1971). Thus, we would expect the cumulative tumor rate to increase by at least the 3rd power of age. Using this fact, we assume that the slope q_1^*, or more generally, the exponent g(d), would also increase by at least the 3rd power of age. As a result, if the slope q_1^* [or g(d)] is calculated at age L_e, we would expect that if the experiment had been continued for the full life span, L, at the given average exposure, the slope q_1^* [or g(d)] would have been increased by at least $(L/L_e)^3$.

This adjustment is conceptually consistent to the proportional hazard model proposed by Cox (1972) and the time-to-tumor model considered by Crump, et al. (1977) where the probability of cancer at age t and dose d is given by $P(d,t) = 1 - \exp[-f(t) \times g(d)]$

4. Calculation of Carcinogenic Potency Based on Human Data. If human epidemiology studies and sufficiently valid exposure information are available for the compound, they are always used in some way. If they show a carcinogenic effect, the data are analyzed to give an estimate of the linear dependence of cancer rates on lifetime average dose, which is equivalent to the factor q_1^*. If they show

---

[*] From "Recommendation of the International Commission on Radiological Protection," page 9, the average breathing rate is 10^7 cm^3 per 8-hour work day and 2×10^7 cm^3 in 24 hours.

no carcinogenic effect when positive animal evidence is available, then it is assumed that a risk does exist but it is smaller than could have been observed in the epidemiologic study, and an upper limit of the cancer incidence is calculated assuming hypothetically that the true incidence is just below the level of detection in the cohort studied, which is determined largely by the cohort size. Whenever possible, human data are used in perference to animal bioassay data.

In human studies, the response is measured in terms of the relative risk of the exposed cohort of individuals compared to the control group. In the analysis of this data, it is assumed that the excess risk, or relative risk minus one, $R(X)-1$, is proportional to the lifetime average exposure, X, and that it is the same for all ages. It follows that the carcinogenic potency is equal to $[R(X)-1]/X$ multiplied by the lifetime risk at that site in the general population. Except for an unusually well-documented human study, the confidence limit for the excess risk is not calculated, due to the difficulty in accounting for the uncertainty inherent in the data (exposure and cancer response).

5. Calculation of Water Quality Criteria. After the value of q_1^* in $(mg/kg/day)^{-1}$ has been determined, the lifetime risk, P, from an average daily exposure of x mg/kg/day is found from the equation $P = q_1^*x$. Therefore, if the lifetime risk is set at $P = 10^{-5}$ for calculation purposes, the intake, I, in mg/day for a 70 kg person can be found by the equation: $I = 70 \times 10^{-5}/q_1^*$
The intake of the agent from ambient water is assumed to come from two sources: (1) drinking an average of 2 liters of water per day, and (2) ingesting an average of 6.5 grams of fish per day. Because of accumulation of residues in fish, the amount of the pollutant in fish (mg/kg of edible fish) is equal to a factor R times the water concentration (mg/kg of water). Therefore, the total intake I can be written as sum of two terms: $I(mg/day) = C(mg/l) \times R(l/kg\ fish) \times 0.0065\ kg\ fish/day + C(mg/l \times 2l/day = C(2 + 0.0065R)$ where C is the water concentration in mg/l. Therefore, the water concentration in mg/l corresponding to a lifetime risk of 10^{-5} for a 70 kg person is calculated by the formula:

$$C = \frac{70 \times 10^{-5}}{q_1^*(2 + 0.0065\ R)}$$

B. Threshold Effects

1. Use of Animal Toxicity Data (Oral). In developing guidelines for deriving criteria based on noncarcinogenic responses, five types of response levels are considered:

NOEL—No-Observed-Effect-Level
NOAEL—No-Observed-Adverse-Effect-Level
LOEL—Lowest-Observed-Effect-Level
LOAEL—Lowest-Observed-Adverse-Effect-Level
FEL—Frank-Effect-Level

Adverse effects are defined as any effects which result in functional impairment and/or pathological lesions which may affect the performance of the whole organism, or which reduce an organism's ability to respond to an additional challenge.

One of the major problems encountered in consideration of these concepts regards the reporting of "observed effect levels" as contrasted to "observed adverse effect levels". The terms "adverse" vs. "not adverse" are at times satisfactorily defined, but due to increasingly sophisticated testing protocols, more subtle responses are being identified, resulting in a need for judgment regarding the exact definition of adversity.

The concepts listed above (NOEL, NOAEL, LOEL, LOAEL) have received much attention because they represent landmarks which help to define the threshold region in specific experiments. Thus, if a single experiment yields a NOEL, a NOAEL, a LOAEL, and a clearly defined FEL in relatively closely spaced doses, the threshold region has been relatively well defined; such data are very useful for the purpose of deriving a criterion. On the other hand, a clearly defined FEL has little utility in establishing criteria when it stands alone, because such a level gives no indication how far removed the data point is from the threshold region. Similarly, a free-standing NOEL has little utility, because there is no indication of its proximity to the LOEL, since a free-standing NOEL may be many orders of magnitude below the threshold region.

Based on the above dose-response classification system, the following guidelines for deriving criteria have been adopted:

a. A free-standing FEL is unsuitable for the derivation of criteria.

b. A free-standing NOEL is unsuitable for the derivation of criteria. If multiple NOELs are available without additional data on LOELs, NOAELs, or LOAELs, the highest NOEL should be used to derive a criterion.

c. A NOAEL, LOEL, or LOAEL can be suitable for criteria derivation. A well-defined NOAEL from a chronic (at least 90-day) study may be used directly, applying the appropriate uncertainty factor. For a LOEL, a judgment needs to be made whether it actually corresponds to a NOAEL or a LOAEL. In the case of a LOAEL, an additional uncertainty factor is applied; the magnitude of the additional uncertainty factor is judgmental and should lie in the range of 1 to 10. Caution must be exercised not to substitute "Frank-Effect-Levels" for "Lowest-Observable-Adverse-Effect-Levels".

d. If for reasonably closely spaced doses only a NOEL and a LOAEL of equal quality are available, then the appropriate uncertainty factor is applied to the NOEL.

In using this approach, the selection and justification of uncertainty factors are critical. The basic definition and guidelines for using uncertainty factors has been given by the National Academy of Sciences (1977). "Safety Factor" or "Uncertainty Factor" is defined as a number that reflects the degree or amount of uncertainty that must be considered when experimental data in animals are extrapolated to man. When the quality and quantity of experimental data are satisfactory, a low uncertainty factor is used; when data is judged to be inadequate or equivocal, a larger uncertainty factor is used. The following general guidelines have been adopted in establishing the uncertainty factors:

a. Valid experimental results from studies on prolonged ingestion by man, with no indication of carcinogenicity. Uncertainty Factor = 10

b. Experimental results of studies of human ingestion not available or scanty (e.g., acute exposure only) with valid results of long-term feeding studies on experimental animals, or in the absence of human studies, valid animal studies on one or more species. No indication of carcinogenicity. Uncertainty Factor = 100

c. No long-term or acute human data. Scanty results on experimental animals with no indication of carcinogenicity. Uncertainty Factor = 1,000

Considerable judgment must be used in selecting the appropriate safety factors for deriving a criterion. In those cases where the data do not completely fulfill the conditions for one category and appear to be intermediate between two categories an intermediate uncertainty factor is used. Such an intermediate uncertainty factor may be developed based on a logarithmic scale (e.g., 33, being halfway between 10 and 100 on a logarithmic scale).

In determining the appropriate use of the uncertainty factors, the phrase "no indication of carcinogenicity" is interpreted as the absence of carcinogenicity data from animal experimental studies or human epidemiology. Available short-term carcinogenicity screening tests are reported in the criteria documents, but they are not used either for derivation of numerical criteria nor to rule out the uncertainty factor approach.

Because of the high degree of judgment involved in the selection of a safety factor, the criterion derivation section of each document should provide a detailed discussion and justification for both the selection of the safety factor and the data to which it is applied. This discussion should reflect a critical review of the available data base. Factors to be considered include number of animals, species, and parameters tested; quality of controls; dose levels; route; and dosing schedules. An effort should be made to differentiate between results which constitute a toxicologically sufficient data base and data which may be spurious in nature.

2. Use of Acceptable Daily Intake (ADI). For carcinogens, the assumption of low dose linearity precludes the necessity for defining total exposure in the estimation of increased incremental risk. For non-carcinogens, ADIs and criteria derived therefrom are calculated from total exposure data that include contributions from the diet and air. The equation used to derive the criterion (C) is: $C = ADI - (DT + IN)/[2\ l + (0.0065\ kg \times R)]$ where 2 l is assumed daily water consumption, 0.0065 kg is assumed daily fish consumption, R is bioconcentration factor in units of l/kg, DT is estimated non-fish dietary intake, and IN is estimated daily intake by inhalation.

If estimates of IN and DT cannot be provided from experimental data, an assumption must be made concerning total exposure. It is recognized that either the inability to estimate DT and IN due to lack of data or the wide variability in DT and IN in different states may add an additional element of uncertainty to the criterion formulation process. In terms of scientific validity, the accurate estimate of the Acceptable Daily Intake is the major factor in satisfactory derivation of water quality criteria.

3. Use of Threshold Limit Values or Animal Inhalation Studies. Threshold Limit Values (TLVs) are established by the American Conference of Governmental and Industrial Hygienists (ACGIH) and represent 8-hour time-weighted average concentrations in air that are intended to protect workers from various adverse health effects over a normal working lifetime. Similar values are set by NIOSH (criteria) and OSHA (standards) for 10- and 8-hour exposures, respectively. To the extent that these values are based on sound toxicologic assessments and have been protective in the work environment, they provide useful information for deriving or evaluating water quality criteria. However, each TLV must be carefully examined to determine if the basis of the TLV contains data which can be used directly to derive a water quality criterion using the uncertainty factor approach. In addition, the history of each TLV must be examined to assess the extent to which it has assured worker safety. In each case, the types of effects against which TLVs are designed to protect are examined in terms of their relevance to exposure from water. It must be demonstrated that the chemical is not a localized irritant and that there is no significant effect at the site of entry irrespective of the routes of exposure (i.e., oral or inhalation).

If the TLV or similar value is recommended as the basis of the criterion, consideration of the above points is explicitly stated in the criterion derivation section of the document. Particular emphasis is placed on the quality of the TLV relative to the available toxicity data that normally is given priority over TLVs or similar established values. If the TLV can be justified as the basis for the cirterion, then the problems associated with the estimation of acceptable oral doses from inhalation data must be addressed.

Estimating equivalencies of dose-response relationships from one route of exposure to another introduces an additional element of uncertainty in the derivation of criteria. Consequently, whenever possible, ambient water quality criteria should be based on data involving oral exposures. if oral data are insufficient, data from other routes of exposure may be useful in the criterion derivation process.

Inhalation data, including TLVs or similar values, are the most common alternatives to oral data. Estimates of equivalent doses can be based upon: (1) available pharmacokinetic data for oral and inhalation routes, (2) measurements of absorption efficiency from ingested or inhaled chemicals, or (3) comparative excretion data when the associated metabolic pathways are equivalent to those following oral ingestion or inhalation. Given that sufficient pharmacokinetic data are available, the use of accepted pharmacokinetic models provides the most satisfactory approach for dose conversions. However, if available pharmacokinetic data are marginal or of questionable quality, pharmacokinetic modeling is inappropriate.

The Stokinger and Woodward (1958) approach, or similar models based on assumptions of breathing rate and absorption efficiency, represents possible alternatives when data are not sufficient to justify pharmacokinetic modeling. Such alternative approaches, however, provide less satisfactory approximations because they are not based on pharmacokinetic data. Consequently, in using the Stokinger and Woodward or related models, the uncertainties inherent in each of the assumptions and the basis of each assumption must be clearly stated in the derivation of the criterion.

The use of data pertaining to other routes of exposure to derive water quality criteria may also be considered. As with inhalation data, an attempt is made to use accepted toxicologic and pharmacokinetic principles to estimate equivalent oral doses. If simplifying assumptions are used, their bases and limitations must be clearly specified.

Because of the uncertainties involved in extrapolating from one route of exposure to another and the consequent limitations that this may place on the derived criterion, the decision to disallow such extrapolation and recommend no criterion is highly judgmental and must be made on a case-by-case basis. A decision for or against criteria derivation must balance the quantity and quality of the available data against a perceived risk to the human population.

If the Stokinger and Woodward (1958) approach is used to calculate an ADI from a TLV, the general equation is: $ADI = TLV \times BR \times DE \times d \times A_A/(A_O \times SF)$ where:

ADI = Acceptable daily intake in mg
TLV = Concentration in air in mg/m^3
DE = Duration of exposure in hours per day
$d = 5$ days/7 days
A_A = Efficiency of absorption from air
A_O = Efficiency of absorption from oral exposure
SF = Safety factor following guidelines given above
BR = Amount of air breathed per day; assume 10 m^3

For deriving an ADI from animal toxicity data, the equation is: $ADI = C_A \times D_E \times d \times A_A \times BR \times 70\ kg/(BW_A \times A_O \times SF)$ where:

ADI = Acceptable daily intake in mg
C_A = Concentration in air in mg/m^3
D_E = Duration of exposure in hours per day
d = Number of days exposed/number of days observed
A_A = Efficiency of absorption from air
BR = Volume of air breathed per day in m^3
70 kg = Assumed human body weight
BW_A = Body weight of experimental animals in kg

A_o = Efficiency of absorption from oral exposure
SF = Safety factor following guidelines given above

More formal pharmacokinetic models must be developed on a compound-by-compound basis.

It should be noted that the safety factors used in the above formulae are intended to account for species variability. Consequently, the mg/surface area/day conversion factor is not used in the derivation of toxicity based criterion.

C. Organoleptic Criteria

Organoleptic criteria define concentrations of materials which impart undesirable taste and/or odor to water. In developing and utilizing such criteria two factors must be appreciated: the limitations of most organoleptic data and the human health significance of organoleptic properties.

The publications which report taste and odor thresholds are, with very few exceptions, cryptic in their descriptions of test methodologies, number of subjects tested, concentration: response relationships, and sensory characteristics at specific concentrations above threshold. Thus, the quality of organoleptic data is often significantly less than that of toxicologic data used in establishing other criteria. Consequently, a critical evaluation of the available organoleptic data must be made and the selection of the most appropriate data base for the criterion must be based on sound scientific judgment.

Organoleptic criteria are not based on toxicologic information and have no direct relationship to potential adverse human health effects. Although sufficiently intense organoleptic characteristics could result in depressed fluid intake which, in turn, might aggravate a variety of functional disease states (i.e., kidney and circulatory diseases), such effects are not used in the derivation process of organoleptic criteria unless available data would indicate an indirect human health effect via decreased fluid consumption, criteria derived solely from organoleptic data are based upon aesthetic qualities only.

Since organoleptic and human health effects criteria are based on different endpoints, a distinction must be made between these two sets of information. In criteria summaries involving both types of data, the following format is used:

> For comparison purposes, two approaches were used to derive criterion levels for ———. Based on available toxicity data, for the protection of public health the derived level is ——. Using available organoleptic data, for controlling undesirable taste and odor quality of ambient water the estimated level is ——. It should be recognized that organoleptic data as a basis for establishing a water quality criteria have no demonstrated relationship to potential adverse human health effects.

In those instances where a level to limit toxicity cannot be derived, the following statement is to be appropriately inserted.

> Sufficient data are not available for ——— to derive a level which would protect against the potential toxicity of this compound.

D. Criteria for Chemical Classes

A chemical class is broadly defined as any group of chemical compounds which are reviewed in a single risk assessment document. In criterion derivation, isomers should be regarded as a part of a chemical class rather than as a single compound. A class criterion is an estimate of risk/safety which applies to more than one member of a class. It involves the use of available data on one or more chemicals of a class to derive criteria for other compounds of the same class in the event that there are insufficient data available to derive compound-specific criteria.

A class criterion usually applies to each member of a class rather than to the sum of the compounds within the class. While the potential hazards of multiple toxicant exposure are not to be minimized, a criterion, by definition, most often applies to an individual compound. Exceptions may be made for complex mixtures which are produced, released, and toxicologically tested as mixtures (e.g., toxaphene and PCBs). For such exceptions, some attempt is made to assess the effects of environmental partitioning (i.e., different patterns of environmental transport and degradation) on the validity of the criterion. If these effects cannot be assessed, an appropriate statement of uncertainty should accompany the criterion.

Since relatively minor structural changes within a class of compounds can have pronounced effects on their biological activities, reliance on class criteria should be minimized. Whenever sufficient toxicologic data are available on a chemical within a class, a compound-specific criterion should be derived. Nonetheless, for some chemical classes, scientific judgment may suggest a sufficient degree of similarity among chemicals within a class to justify a class criterion applicable to some of all members of a class.

The development of a class criterion takes into consideration the following:

1. A detailed review of the chemical and physical properties of chemicals within the group should be made. A close relationship within the class with respect to chemical acitivity would suggest a similar potential to reach common biological sites within tissues. Likewise, similar lipid solubilities would suggest the possibility of comparable absorption and tissue distribution.

2. Qualitative and quantitative data for chemicals within the group are examined. Adequate toxicologic data on a number of compounds within a group provides a more reasonable basis for extrapolation to other chemicals of the same class than minimal data on one chemical or a few chemicals within the group.

3. Similarities in the nature of the toxicologic response to chemicals in the class provides additional support for the prediction that the response to other members of the class may be similar. In contrast, where the biological response has been shown to differ markedly on a qualitative and quantitative basis for chemicals within a class, the extrapolation of a criterion to other members of that class is not appropriate.

4. Additional support for the validity of extrapolation of a criterion to other members of a class could be provided by evidence of similar metabolic and pharmacokinetic data for some members of the class.

Based on the above considerations, it may be reasonable in some cases to divide a chemical class into various subclasses. Such divisions could be based on biological endpoints (e.g., carcinogens/non-carcinogens), potency, and/or sufficiency of data (e.g., a criterion for some members of a class but no criterion for others). While no *a priori* limits can be placed on the extent of subclassification, each subclassification must be explicitly justified by the available data.

Class criteria, if properly derived and supported, can constitute valid scientific assessments of potential risk/safety. Conversely, the development of a class criterion from an insufficient data base can lead to serious errors in underestimating or overestimating risk/safety and should be rigorously avoided. Although scientific judgment has a proper role in the development of class criteria, such criteria are useful and defensible only if they are based on adequate data and scientific reasoning. The definition of sufficient data on similarities in physical, chemical, pharmacokinetic, or toxicologic properties to justify a class criterion may vary markedly depending on the degree of structural similarity and the gravity of the perceived risk. Consequently, it is imperative that the criterion derivation section of each document in which a class criterion is recommended explicity address each of the key issues discussed above, and define, as clearly as possible, the limitations of the proposed criterion as well as the type of data needed to generate a compound-specific criterion.

A class criterion should be abandoned when there is sufficient data availabe to derive a compound-specific criterion which protects against the biological effect of primary concern; e.g., the availability of a good subchronic study would not necessarily result in the abandonment of a class criterion based on potential carcinogenicity.

The inability to derive a valid class criterion does not, and should not, preclude regulation of a compound or group of compounds based on concern for potential human health effects. The failure to recommend a criterion is simply a statement that the degree of concern cannot be quantified based on the available data and risk assessment methodology.

E. Essential Elements

Some chemicals, particularly certain metals, are essential to biological organisms at low levels but may be toxic and/ or carcinogenic at high levels. Because of potential toxic effects, it is legitimate to establish criteria for such essential elements. However, criteria must consider essentiality and cannot be established at levels which would result in deficiency of the element in the human population.

Elements are accepted as essential if listed by NAS Food and Nutrition Board or a comparably qualified panel. Elements not yet determined to be essential but for which supportive data on essentiality exists need to be further reviewed by such a panel.

To modify the toxicity and carcinogenicity based criteria, essentiality must be quantified either as a "recommended daily allowance" (RDA) or "minimum daily requirement" (MDR). These levels are then compared to estimated daily doses associated with the adverse effect of primary concern. The difference between the RDA or MDR and the daily doses causing a specified risk level for carcinogens or ADIs for non-carcinogens defines the spread of daily doses from which the criterion may be derived. Because errors are inherent in defining both essential and maximum tolerable levels, the criterion is derived from dose levels near the center of such a dose range. The decision to use either the MDR or RDA is guided by the spread of the doses and the quality of the essentiality and toxicity estimates.

The modification of criteria by consideration of essentiality must take into account all routes of exposure. If water is a significant source of the MDR or RDA, the criterion must allow for attainment of essential intake. Conversely, even when essentiality may be attained from nonwater sources, standard criteria derivation methods may be adjusted if the derived criterion represents a small fraction of the ADI or MDR. On a case-by-case basis, the modification in the use of the guidelines may include the use of different safety factors for non-carcinogens or other modifications which can be explicitly justified.

F. Use of Existing Standards

For some chemicals for which criteria are to be established, drinking water standards already exist. These standards represent not only a critical assessment of literature, but also a body of human experience since their promulgation. Therefore, it is valid to accept the existing standard unless there is compelling evidence to the contrary. This decision should be made after considering the existing standards vs. new scientific evidence which has accumulated since the standards have been established. There are several instances where the peer review process recommended usage of the present drinking water standards.

Appendix D—Response to Comments on Guidelines for Deriving Water Quality Criteria for the Protection of Aquatic Life and Its Uses

Introduction

Two versions of the Guidelines were published in the **Federal Register** for comment. The first version (43 FR 21506, May 18, 1978 and 43 FR 29028, July 5, 1979) was simply published for comment. The second (44 FR 15926, March 15, 1979) was published as part of the request for comments on the water quality criteria for 27 of the 65 pollutants. The second version was meant to be clearer and more detailed than the first, but very similar technically. Since the two versions were so similar, comments on both will be dealt with simultaneously.

Many comments were received that no draft water quality criteria for any of the 65 pollutants should have been issued for public comment until the comments on the first version of the Guidelines had been dealt with adequately and the Guidelines changed appropriately. The comments on the first version were read and the Guidelines were revised in an attempt to make the second version clearer and more detailed than the first. However, an extensive revision of the technical content of the Guidelines was not attempted between the first and second versions because the Agency was preparing water quality criteria based on the Guidelines. The Agency could have avoided this criticism simply by not publishing any version of the Guidelines for comment until March 15, 1979, but this would have greatly reduced the length of time available for people to consider the Guidelines and comment on them. As it was, some people commented that the comment period announced on March 15, 1979, was too short.

1. Comment—The procedures used to derive criteria in the "Red Book" were upheld in court and probably should still be used.

Response—The procedures used in the Guidelines are similar to some of the procedures used to develop criteria in the "Green Book", "Blue Book", and "Red Book". The Guidelines are designed to be more objective and systematic, to deal more adequately with residues, and to incorporate the concept of a minimum data base.

2. Comment—Criteria should be compilations of critically reviewed data with no synthesis or interpretation.

Response—Neither P.L. 92-500 nor the Consent Decree specify the form which a criterion must take. The Consent Decree (para. 11, p. 14) specifies that such criteria "shall state, *inter alia*, recommended maximum permissible concentrations". Adequate precedents have been set in the "Green Book", "Blue Book", and "Red Book" for the form of criteria used in the Guidelines.

3. Comment—The Guidelines and criteria should be developed by a consensus of aquatic toxicologists rather than by EPA personnel only.

Response—EPA certainly wants the Guidelines and the criteria to be as good as possible and as acceptable to as many interested people as possible. To this end, EPA has widely distributed draft versions of the Guidelines and the criteria documents, discussed them with many people, considered the comments received, and made many significant technical changes and editorial revisions. It is questionable whether or not a true consensus could have been reached by any means within the time available. In addition, EPA has a legislative responsibility which it should not delegate to someone else.

4. Comment—The Guidelines should be updated regularly.

Response—The Guidelines are not being promulgated as a regulation or directive. The purpose of presenting these Guidelines is to show how the water quality criteria for aquatic life were derived for the 65 pollutants. If EPA uses these Guidelines again, they will be revised to take into account new data, concepts, and ideas.

5. Comment—The objectives, purpose, and limitations of the Guidelines should be stated.

Response—The introductory portion of the Guidelines has been expanded to address these subjects more fully.

6. Comment—The Guidelines are too ambiguous.

Response—The Guidelines have been revised and rewritten, partly to improve clarity and provide additional details. It is not possible to provide explicit details on all items; in some areas only general guidance can be provided at this time.

EPA attempted to clearly and concisely deal with all issues which might significantly affect the resulting criteria without going into extreme detail on every potential problem. Because numerous judgments must be made, a reasonable amount of experience in aquatic toxicology will be necessary for a person to utilize the Guidelines effectively.

7. Comment—The Guidelines are too complex.

Response—Deriving a water quality criterion is a complex exercise because several different kinds of data and a wide variety of organisms need to be considered. In addition, because data have been generated using various procedures, numerous individual decisions need to be made and the Guidelines attempt to provide guidance concerning decisions that seem to need to be made frequently. The Guidelines are more complex than initially envisioned to help insure that criteria for different pollutants are derived in a reasonably comparable manner. Although the process of deriving a water quality criterion for aquatic life is complex, the Guidelines help organize the process into logical components and steps.

8. Comment—The Guidelines should be more flexible.

Response—The Guidelines are meant to provide guidance and at the same time allow reasonable flexibility. They have been used with quite a variety of pollutants for which the requirements of the minimum data base are satisfied, and they seem to be reasonably appropriate in all cases because the experiences with these substances were a major part of the basis for the Guidelines. If sound scientific evidence indicates that a particular aspect of the Guidelines is not appropriate for a specific substance, then some other more appropriate procedure should be used. However, the Guidelines should not be changed based on individual whim or personal preference.

9. Comment—The Guidelines should take into account synergism and antagonism by a wide variety of factors and the effect of the pollutant on important ecological relationships.

Response—Very little practically useful information is available on these factors in connection with the effects of pollutants on aquatic organisms. Synergism and antagonism are possible between numerous combination of two or more pollutants, and some data indicate that such interactions are not only species specific, but also vary with the ratios and absolute concentrations of the pollutants and the life stage of the species. Pollutants may affect the structure and function of aquatic ecosystems separate from their effects on individual species, but practical applications of such ideas seem very tenuous at this time. Little information is available concerning such effects, and the significance of the available data is questionable. An obviously important ecological relationship is the dependence of higher organisms on lower organisms for food. Even here, the existence of numerous lower species and their adaptability reduces the importance of any individual food species.

10. Comment—The Guidelines should take into account all identifiable effects—beneficial as well as harmful.

Response—Few tests have been conducted to identify beneficial effects of individual pollutants on aquatic organisms. However, beneficial effects are sometimes observed in chronic toxicity tests at concentrations below those that cause adverse effects. Usually in such cases the organisms in low concentrations of the pollutant are longer or heavier or reproduce more that do the controls. Even if such effects are statistically significant, they are not judged as adverse or harmful. On the other hand, a beneficial effect on one species may ultimately be to the detriment of a community if a balance between species is disturbed. Also, a concentration that benefits one species may harm a more sensitive species.

11. Comment—The Guidelines should take into account analytical methodology.

Response—The Guidelines do take into account analytical methodology in the definition of the substance, when necessary, but not in deriving the numerical value of the criterion. Concentrations which cannot be routinely measured accurately can often be measured accurately by nonroutine methods and, more importantly, do sometimes adversely affect aquatic organisms. When aquatic organisms are more sensitive than routine analytical methods, the proper solution is to develop better analytical methods, not to underprotect aquatic life. One use of criteria should be to identify needs in analytical chemistry.

12. Comment—The Guidelines should take into account (a) production and usage patterns, (b) chemical, physical and biological factors pertaining to degradation and fate of pollutants, including properties such as solubility in water, decay rate, persistence, and transformation pathways, and (c) whether or not a criterion is needed for the substance.

Response—Items included in (a) and (b) may be important in deciding whether a criterion is needed for a substance, but the Guidelines are intended to be used after the decision has been made that a criterion is needed. EPA is presently developing principles that can be used to decide whether or not a criterion is needed for a substance and items such as those listed above are probably some of the factors that should be considered when deciding whether or not a criterion is needed. If the toxicity of the chemical is used to evaluate the need for a criterion, the Guidelines may be useful in the collection and interpretation of the available toxicity data.

13. Comment—The Guidelines should take into account costs to states and industries, technological feasibility, and such characteristics of bodies of water as assimilative capacity, dispersal, dissipative factors, dilution, hydrology, mixing zones, and sediment.

Response—Factors such as these should be considered in developing standards, but not in deriving criteria. EPA is presently developing an implementation policy which will describe which of the above factors and which characteristics of the pollutant should be used, and how they should be used, in developing standards.

14. Comment—The Guidelines are not appropriate for establishing a concentration which may be present in an effluent.

Response—The Guidelines are for deriving water quality criteria, not effluent standards nor mixing zone standards nor water quality standards. Water quality criteria will probably be one factor taken into account in the development of water quality standards and toxicity-based effluent standards, but not technology-based effluent standards. EPA is presently developing policies concerning proper use of water quality criteria in various regulatory activities.

15. Comment—The derivation of criteria should be fundamentally a scientific exercise and should not employ subjective judgments.

Response—No exercise which involves the use and interpretation of data can avoid subjective judgment. Indeed, even the generation of scientific data requires subjective judgment, such as how many test organisms to use, what temperature to use, etc. One may decide to accept the recommendations of experts, but this is usually still a subjective decision. In statistics the subjective decisions are made on the basis of probability statements but the final decisions are still subjective judgments. Although the development of the Guidelines and the derivation of criteria cannot avoid subjective decisions, gross extrapolations, wild assumptions, and novel judgments can be avoided. One can also avoid using large safety factors to "make up" for insufficient data. When some agreement exists between experts, such as on test temperature and duration of tests, the collective opinion can usually be used. EPA feels that the Guidelines do not go too far beyond the state-of-the-art and do not produce criteria by extrapolating far beyond the usefulness of the data.

16. Comment—The Guidelines should not use unproven extrapolations.

Response—EPA feels that the extrapolations used in the Guidelines are reasonable for most pollutants. Probably the most questionable extrapolation is the acute-chronic ratio, but even here an arbitrary ratio is not used. Indeed, the ratio used is usually a mean of experimentally determined acute-chronic ratios for at least three, not just one, species. In addition, the species must include at least one fish and one invertebrate. Even this amount of data does not "prove" the validity of the extrapolation, but it should provide reasonable evidence for or against the use of the ratio with any particular substance. To achieve reasonable criteria without using any extrapolations would require acute and chronic tests with many more species. This would be a high price to pay for disallowing any use of scientific inference in deriving criteria.

The early versions of the Guidelines used adjustment factors and sensitivity factors which were averages derived from data for a wide variety of substances and thus were attempts to make some extrapolations across all substances. The present version of the Guidelines is based on a minimum data base for each individual pollutant and the calculations are essentially pollutant-specific. Thus no extrapolations are made from one pollutant to another.

17. Comment—Laboratory tests overestimate the toxicity of materials because the test organisms are stressed by the artifical conditions.

Response—Laboratory conditions certainly are artificial, but they do not necessarily stress the test organisms. Organisms which survive, grow, and reproduce well in the laboratory cannot be stressed too much. Organisms in a laboratory might be considered pampered because they do not have to compete for food and are not subject to stress due to predators and changing and extreme conditions of turbidity, temperature, flow, and water quality. Also, laboratory organisms are rarely subject to stress from pollutants. Some species probably have longer average life spans in laboratories than they do in field situations.

18. Comment—Laboratory tests underestimate the toxicity of materials because the tests are usually conducted with species which are hardy, adaptable, and insensitive.

Response—Species which are readily adaptable to laboratory conditions are not necessarily insensitive as evidenced by the great range of sensitivities obtained in laboratory tests for some individual pollutants with different species. In fact, once the the proper techniques are developed, a wide variety of species can survive, grow, and reproduce well in laboratories. When the proper techniques are discovered and a species changes form "difficult" to "easy", its sensitivity does not change. Also, some species and life stages which are fragile and must be handled with great care are not particularly sensitive. On the other hand, because so few species have actually been tested in laboratories, species which are more sensitive than any of those tested in laboratories, species which are more sensitive than any of those tested probably exist for most substances.

19. Comment—Laboratory tests are artificial and contrived and do not represent the real world.

Response—Laboratory tests are indeed artificial but they are not contrived to give results that are unnecessarily high or low. Organisms in a laboratory are generally acclimated to water and conditions of constant and desirable quality, whereas in the field they are often subjected to fluctuations and extremes. Organisms in a laboratory do not have to compete for food and are not subject to predators or pollution. Organisms in the field are often exposed to more than one pollutant at a time, with the combinations and concentrations changing often.

It is true that aquatic organisms are usually exposed to instantaneous high concentrations in laboratory tests, but in field situations organisms are often not given much chance to acclimate to spills or short-term discharges. Also, some ameliorating effects occur in field, but not laboratory, situations, but such effects are not always dependable over long periods of time. The concentrations of mitigating anions, suspended solids, and complexing agents are relatively constant in some bodies of water, but not in others. Suspended solids probably do sorb and detoxify significant amounts of some pollutants, but high concentrations of suspended solids also stress some aquatic organisms. In addition, organisms are usually fed in chronic tests, so the test solution contains suspended solids and dissolved organic carbon from the food and fecal matter. Degradation and other transformations are more likely in field situations than in laboratory situations, but degradation products are not always less toxic than the undegraded material. On the other hand, many of these kinds of considerations will probably be taken into account when site-specific criteria and standards are developed under the implementation policy which is being developed by EPA.

20. Comment—Laboratory tests are poor predictors of what will happen in field situations.

Response—If conditions are comparable, laboratory toxicity tests are useful predictors of what will happen in field situations. The usefulness of such predictions will depend on how carefully one accounts for differences between species, water quality, and the form of the pollutant. Extrapolations are much more difficult for some pollutants than for others. Water quality affects the toxicity of some pollutants much more than others, and species differences, even within families, are much greater for some pollutants than for others. If such factors are taken into account, useful predictions are possible. In what is probably the most extensive comparison available of laboratory and field data (Geckler, J. R., et al. 1976. Validity of Laboratory Tests for Predicting Copper Toxicity in Streams. EPA-600/3-76-116. U.S. EPA. Duluth, MN 208 pp.), it was found that effects observed in laboratory exposures were also observed in field exposures. However, avoidance, which was not studied in laboratory exposures, was observed in the field exposures. Laboratory to field comparisons are not simple because several factors must be taken into account, the laboratory test must be conducted well and the field observations and measurements must be extensive. Although adverse effects observed in laboratory tests will usually occur in similar field situations, a problem exists with the bioaccumulation of some persistent substances. For example, PCB's seem to bioaccumulate to much higher levels in some bodies of water than they do in laboratory tests.

21. Comment—The Guidelines should place more emphasis on field information than on laboratory information.

Response—Field information on effects of pollutants on natural populations is acceptable, but the collection of definitive information of this type is high risk and costly. Few studies on the effects of pollution on natural populations provide definitive information because of the multitude of variables that need to be taken into account. The major advantage of field studies is that conditions are natural (i.e., conditions are not controlled), but this is also the major problem with field studies. With uncontrolled conditions, numerous variables must be taken into account, because any individual variable or combination of variables may affect the results or indeed may be the cause of the results. Therefore, field studies on natural populations usually must last over several seasons and possibly over more than one year to be reasonably sure that proposed cause-and-effect relationships are real.

Another problem with field studies that are based on statistically significant differences is the power of the test. Because natural biological, spacial, and temporal variability is often rather great, a large number of samples is usually required to detect even a moderate change. A field study which purports to show that no change occurred is of no value if the power of the test calculated from the experimental design and observed variability was not high enough.

Because field studies are high cost-high risk ventures, well-designed laboratory tests are usually much more cost-effective for obtaining data on (1) the toxicity of substances to a variety of species and (2) the effect of various water quality characteristics on toxicity. Laboratory tests have been shown to generally be useful predictors of what happens in a field situation, and so it makes little sense to conduct high risk, high cost field studies rather than laboratory tests. Even definitive field studies rarely provide enough information to allow extrapolation of results to other situations, so field studies are more useful in reviewing criteria than in deriving criteria.

22. Comment—Field verification of laboratory tests and of the Guidelines are needed.

Response—Field verification of laboratory tests end of the Guidelines are certainly desirable and provide information that cannot be obtained in a laboratory. Field verification studies do not need to be as risky or as costly as studies on the effects of a pollutant on natural populations because verification studies can be designed (1) as a side-by-side comparison of the results of laboratory tests and field tests or (2) based on existing results of laboratory tests.

23. Comment—EPA should allow criteria to be derived using on-site acute toxicity tests and an application factor.

Response—This approach is usually suggested for developing effluent standards but may be just as applicable to deriving water quality criteria under certain conditions. This approach cannot be used with pollutants whose most sensitive adverse effect is due to residues. Also, it can only be used when the application factor has already been acceptably determined. Finally, acute tests must be determined with either an appropriate range of species or with an appropriate sensitive species. The implementation policy presently being developed by EPA will probably allow the use of appropriate on-site toxicity tests in the development of site-specific criteria and standards.

24. Comment—It is not clear what level of protection is intended.

Response—EPA feels that it is not possible to specify a minimum level of protection that is necessary to "protect aquatic life" or even to protect a particular species for such reasons as:

a. There are so many untested species.

b. Little practically useful information is available concerning synergism, antagonism, ecological relationships, and avoidance.

c. The effect of factors such as temperature on toxicity seems to be species-specific for at least some substances.

d. Information is not available concerning what amount of any effect would be ecologically significant and whether the amount is species-specific.

One possible conclusion is that to protect aquatic life, all species must be adequately protected. A possible extension of this would be that all criteria should be zero because any amount of any pollutant may affect some aquatic organism. Indeed, the assimilative capacity of body of water largely depends on the ability of aquatic life to "process" pollutants and to some extent, any organism which "processes" a pollutant is in some way affected by it.

The apparent level of protection is different for each kind of effect (acute toxicity to animals, chronic toxicity to animals, toxicity to plants, and bioaccumulation) because of the quality and quantity of the available information. An attempt was made to take into account such things as the importance of the effect, the quality of the available data, and the probable ecological relevance of the test methods. Thus it was felt that with regards to toxicity to animals it was probably not necessary to protect all of the species all of the time, but it certainly seems appropriate to protect most of the species most of the time and to protect important species.

On the other hand, the data base on toxicity to aquatic plants is usually very small and a variety of tests and endpoints have been used, especially with algae. Also, little information is available concerning the ecological relevance of the results of any toxicity test with algae in a concentrated test medium, especially because so many species of algae exist in each body of water.

The results of bioconcentration tests with organic chemicals, but not with inorganic chemicals, can apparently be extrapolated reasonably well based on percent lipids from one aquatic animal species to another, at least within commercially and recreationally important species. In addition, the limits on acceptable concentrations in tissue are reasonably well defined in some cases.

These kinds of considerations merely illustrate the complexity of the problem and the necessity for making decisions about each kind of effect individually. In addition, it is important to distinguish between the apparent level of protection provided by the Guidelines and the actual level of protection which will result in a field situation from the use of the implementation policy.

No attempt was made to develop Guidelines which would achieve a predetermined numerical level of protection. For each effect much desirable information is not available, and so it would be misleading to imply a level of sophistication that is not currently possible. EPA believes that the present state-of-the-art in aquatic toxicology does allow some useful conclusions about the ability of a substance to adversely affect aquatic organisms and their uses whenever the requirements of the minimum data base are satisfied, with the full realization that the resulting criterion may be somewhat overprotective or underprotective.

In almost all cases more data would be desirable and so an attempt to reach the "golden mean" will sometimes result incriteria being to high and sometimes too low. One alternative is to derive no criteria until all desirable data are available; this is unacceptable because it will almost always result in no criteria and no protection. The other alternative is to apply safety or uncertainty factors that are inversely proportional to the adequacy of the data base. In the long run this approach would encourage the generation of useful data where it was most needed, but in the short run would require many significant subjective decisions beyond the current state-of-the-art.

25. Comment—The Guidelines should not base criteria on "worst case" assumptions.

Response—The phrase "worst case assumptions" usually refers to the assumption that both the worst water quality and the most sensitive life stage occur at all times. These two assumptions are a natural result of the two concepts that criteria should be constant throughout the year and that aquatic life is not adequatley protected if it is not adequately protected throughout the year. The implementation policy being developed by EPA will determine whether site-specific criteria must be constant throughout the year. If not, then the "worst case assumptions" will not apply. Although the Guidelines might be viewed as making the "worst case assumptions", the implementation policy will determine whether the site-specific water quality criteria and standards will be based on these assumptions.

26. Comment—Safety factors should be used to protect against such things as potential subtle, but important, long term effects.

Response—Pollutants may cause many direct and indirect adverse effects which have not been studied adequately. For instance, some substances may make aquatic organisms more susceptible to disease or other stresses. in spite of such possibilities, the available information indicates that the major possible adverse effects are covered in the Guidelines and that adequate protection will usually be achieved without the use of safety factors. Safety factors would certainly offer additional protection, but the available information does not show that significant additional protection is needed.

Safety factors of from 10 to 1000 are often used to protect people mainly because people feel that people are more important than aquatic organisms and because humans are usually protected on the basis of tests with other species of animals, thus resulting in a greater uncertainty in the applicability of the results. Complete protection can only be achieved by setting all criteria at zero. Unfortunately, even "Mother Nature" sometimes seriously harms large groups of aquatic organisms, such as during droughts or severe winter freezes. EPA feels that complete protection is neither feasible, desirable, nor possible. In addition, aquatic ecosystems can recover from some adverse effects.

27. Comment—The Guidelines do not provide for an adequate margin of safety.

Response—If "margin of safety" is interpreted to mean "safety factor", then the Guidelines do not provide a margin of safety. If the Guidelines are viewed as deriving criteria for a constant quality water, then they provide a margin of safety during those portions of the year during which the most sensitive life stage does not occur. Although some species may occasionally be adversely affected, EPA feels that the Guidelines provide adequate safety because aquatic communities and their uses should not incur any substantial or permanent damage. Whether or not site-specific criteria will have a margin of safety will depend on how they are derived.

28. Comment—Criteria should be set at the least restrictive concentration and states can then apply more restrictive concentrations when necessary.

Response—It is unclear what is meant by the "least restrictive concentration" but presumably it would be a concentration which would not protect very many aquatic communities and their uses. This is contradictory to the concept that criteria are to protect aquatic life and its uses. The implementation policy being developed by EPA will allow site-specific criteria to be higher or lower than the criteria derived using the Guidelines, when adequate information is available.

29. Comment—The Guidelines should produce criteria in the form of a concentration-risk curve with appropriate confidence limits for each kind of effect.

Response—EPA feels that a risk analysis approach is certainly desirable, but far beyond the state-of-the-art at this time. When dealing with safety to humans, only one species is being protected and extrapolations are made far outside the limits of the actual test results, such as to 1 death in 100,000 people. With aquatic life, numerous species need to be protected and extrapolation far beyond the actual data is not readily accepted. In addition, safety or uncertainty factors are more readily accepted when protecting people than when protecting aquatic organisms.

Most aquatic toxicologists are not willing to let criteria for the protection of aquatic life be as dependent on mathematical models, assumptions, and manipulations as on the actual test results. Most people with experience in aquatic toxicology have an intuitive "feel" about how data should be interpreted and the Guidelines are merely an attempt to formalize a reasonable approach. The Guidelines could be written as mathematical algorithms and some approach such as error models could be developed in order to derive confidence limits. However, the algorithms and models would contain many unproven assumptions and, to be worthwhile, would undoubtedly require more data than are usually available. Although such models and algorithms would be acceptable to many statisticians and may be an appropriate future goal, the current Guidelines need to be useable by and comprehensible to current aquatic toxicologists. Most experienced aquatic toxicologists will judge the reasonableness of any set of Guidelines by comparing the resulting criteria for various pollutants with the data available for those pollutants using a "common sense" interpretation of data.

30. Comment—The Guidelines should not use unsound statistical procedures or misuse sound statistical procedures.

Response—EPA has tried to make sure that no statistical procedures are misused in the Guidelines, that no unsound statistical procedures are used, and that the purposes of the calculations are explained adequately.

31. Comment—It appears that geometric means were used instead of arithmetic means in the Guidelines to obtain lower values.

Response—Decisions such as this were made throughout the Guidelines on a case-by-case basis, and none were based on whether the resulting criteria would be higher or lower. The selection of the procedure used to calculate the mean could be based on the distribution of the values in the individual data set. Unfortunately, with small data sets rarely is it possible to reject many possible distributions and with large data sets all possible distributions are often rejected. Because many of the data sets of interest in the Guidelines are small, a reasonable approach is to base the selection of a procedure for calculating the mean on some general principles such as:

a. Sets of ratios and quotients are likely to be closer to lognormal than normal distributions. Thus geometric means, rather than arithmetic means, are used for acute-chronic ratios and for bioconcentration factors.

b. When there are numerous independent possible sources of error for each datum in a set, the error tends to be multiplicative rather than additive. Thus when the acute or chronic toxicity of a substance to a particular species is determined in different laboratories using different batches of organisms, different waters, etc, the geometric means should be used to calculate the species mean value rather than the arithmetic mean.

c. If a set of numbers approximates a lognormal distribution, the logarithms of the numbers will approximate a normal distribution.

d. The distribution of the sensitivities of individual organisms in a toxicity test is likely to be closer to a lognormal distribution than a normal distribution. Thus the geometric mean, rather than the arithemetic mean, of the upper and lower chronic limits is used.

32. Comment—There should not be any criteria which apply to all bodies of water. Criteria should be specific for individual states, regions, other geographic areas, or bodies of water.

Response—The Guidelines are designed to provide guidance in the collection and interpretation of data concerning the effects of pollutants on aquatic life and its uses. The uses of the resulting criteria will be described by EPA in various regulations. If desired, the Guidelines can be appropriately modified and used to derive a criterion specific to one or more bodies of water or geographic areas if an appropriate data base is available. The critical literature reviews on which the criteria are based will be available for use in the derivation of local, state, or regional criteria. The latitude allowed for deriving local, state, or regional criteria and standards will be determined by the implementation policy presently being developed by EPA.

33. Comment—The Guidelines should result in criteria that are specific for individual species or groups of species (e.g., warmwater and coldwater).

Response—If the necessary data were available, criteria could be derived for any particular species or group of species. It was impractical for EPA to derive criteria for many such groups, but a relatively simple division is freshwater and saltwater organisms because these two groups rarely coexist. Most other possible general divisions of species are faced with the problem that species coexist in various combinations unless the groups are very narrow. In addition, toxicity data are rarely available for very many individual species and so data for representative species must be used, unless appropriate new data are generated. Also, the available data sometimes show wide differences within families so extrapolations from one species to another are often tenuous. Because of these problems, deriving criteria for individual species or groups of species was deemed impractical.

34. Comment—A criterion should be one number, not two.

Response—The two-number criterion is an acknowledgement that aquatic organisms can tolerate short exposures to concentrations that are higher than those they can tolerate continuously. In a two-number criterion, the higher number can assure that short-term fluctuations above the average are not too high, whereas the lower number can assure that the long-term average is not too high. A one-number criterion could be derived by using the existing 24-hour average as an instantaneous maximum. This would certainly provide additional protection, but would provide unnecessary overprotection in most cases. Because a one-number criterion would be more of an approximation than a two-number criterion, one-number criteria would be too high or too low more often and to a greater degree then two-number criteria.

35. Comment—The criteria should not specify sampling schemes.

Response—Criteria should state numerical concentration limits in terms of exposure durations because, everything else being constant, the amount of adverse effect depends on both the concentration of the pollutant and the duration of exposure. Criteria in the Green Book, Blue Book, and Red Book were usually stated as single numbers with no duration expressly stated. The implication was that the criteria were never to be exceeded at any time. Each criterion was apparently and instantaneous maximum. In practice, however, standards derived from these criteria were usually enforced on the basis of 24-hour composite samples. To avoid any ambiguity, the Guidelines specify that a criterion should be explicitly stated in terms of two time frames: an instantaneous maximum and a 24-hour average. However, this is not a specification for a sampling scheme. Standards developed from such a criterion should probably specify a sampling scheme for compliance monitoring, but it would not necessarily be in terms of point measurements and 24-hour averages.

Any sampling scheme used to determine whether or not an ambient concentration exceeds a water quality criterion or a comparable water quality standard should take into account such things as the ratio of the instantaneous maximum and the 24-hour average and the retention time of the body of water because these will primarily determine which portion of the criterion is most limiting in any specific situation. The sampling scheme should probably also take into account the cost of the analyses and results of any past analyses.

36. Comment—The criteria should be stated in terms of time frames longer that an instantaneous maximum and a 24-hour average.

Response—These two time frames were chosen because they would allow the derivation of a criterion which would be less restrictive than, but just as protective as, the previous one-number criterion. These two specific time frames were chosen because they match two kinds of samples that are commonly collected: grab samples and 24-hour composite samples. These specific time frames could probably be changed somewhat without much practical effect, but EPA saw no particular advantage to anyone to introducing novel time periods. For example, for all practical purposes in most situations a 10-minutes average is probably about the same as an instantaneous maximum.

Large increases in the time frames, however, would not provide the same amount of protection. If the instantaneous maximum were changed to a 24- or 96-hour average, and the 24-hour average were changed to a 7- or 30-day average with no change in the numerical limits, the amount of protection afforded aquatic life would fall to an unacceptable level. The longer the time span for the average, the higher the instantaneous concentration could be for short periods of time within that span. Although most chronic tests last for 28-days or longer, some chronic effects may be caused by short exposures of sensitive life stages. If the acute-chronic ratio is small, fluctuations in the instantaneous concentration may even cause acute toxicity, especially for cumulative pollutants, because for some substances the 24-, 48-, and 96-hour acute values do not differ too much.

37. Comment—A two-number criterion will be difficult to enforce.

Response—Criteria are not enforceable. Standards are enforceable. When standards to protect aquatic life are developed, they may or may not be in the same format as the criteria for aquatic life. Few standards are adequately enforced because of the high cost of continuous monitoring. The real value of many criteria and standards is in the design of waste treatment facilities; a two-number criterion should be a better basis for design than a one-number criterion.

38. Comment—The criteria should be expressed to one significant figure, not two.

Response—EPA acknowledges that there is much variability in some of the data and that the range of sensitivities is often great. When the requirements of the minimum data base are satisfied and the data agree reasonably well, two significant figures are not unreasonable. Rounding off to one significant figure could arbitrarily raise or lower the criterion by up to forty percent with no apparent consistent benefits to dischargers, regulators, or aquatic life.

39. Comment—The Guidelines should only use data for species that ought to be protected.

Response—In order to protect commercially and recreationally important species, a wide variety of "unimportant" species must also be protected. Such so-called "unimportant" species include the food organisms all the way to the bottom of the food chain. The "important" species in an aquatic community cannot maintain themselves without the help of primary producers, primary consumers, nitrifiers, dentrifiers, detritivores and saprophytes.

40. Comment—Criteria should not be based on sensitive, short-lived invertebrates.

Response—Many species of invertebrates are short-lived and are not widely distributed. However, these numerous short-lived, local species do serve important functions and should be represented in the data base. This group of organisms needs to be protected even if no one species can be considered important.

41. Comment—Criteria should protect endangered species.

Response—EPA agrees that criteria should protect endangered aquatic species. However, very few toxicity tests have been conducted with endangered species, and it does not appear feasible to require tests with such species. Endangered species are some of the many untested species which should be protected by criteria derived from available data using the Guidelines.

42. Comment—Migratory species are a special problem.

Response—Migratory species should usually be protected by criteria derived using the Guidelines unless such species are unusually sensitive. Migratory species may be especially susceptible to avoidance, but few data are available to compare species on this basis. Avoidance may be a serious latent problem because it might apply to all motile species, rather than just migratory species, and it has not been studied very much.

43. Comment—Estuarine species were ignored.

Response—The term "saltwater organisms" is meant to include estuarine species as well as true marine species.

44. Comment—The classification "invertebrates" includes species that are too dissimilar to be grouped together. These species should be separated into phyla or classes.

Response—The never-ending arguments between the "lumpers" and the "splitters" can only be resolved by considering the advantages and disadvantages of each approach in each situation. The "splitters" can usually argue that obvious differences should be taken into account and it is certainly true that shrimp are different from insects and both are different from worms. It can also be argued that there are significant differences within phyla, classes, and families. Each species could be considered a separate group, if differences between stains are arbitrarily ignored. After the species are split into separate groups, the problem then would be whether to recombine the data to derive one criterion for all species or to derive one criterion for each group. If numerous criteria are derived for a pollutant, how are these to be used to develop standards? Another problem is that unless more data are generated, the greater the number of groups, the less information there is available per group.

The basic question is "What are the important differences that need to be taken into account and how should this be done?" Because there are differences between taxonomic groups, the Guidelines require data on a number of species from a varitety of taxonomic groups. The information of each separate species is treated individually. This approach preserves the differences between species and allows all species to be considered in the development of the criterion. The number of data points is increased and the range of the data is readily apparent. Because "invertebrates" is already a large diverse group and because the range of sensitivities of fish usually overlaps that of invertebrates, little justification exists for not combining all aquatic animals.

45. Comment—Do not extrapolate from freshwater organisms to saltwater organisms or vice versa.

Response—Criteria and absolute toxicity values were not extrapolated from fresh water to salt water, but some relative data were, when it did not appear that factors such as salinity affected the data. The toxicity of some substances apparently is significantly affected by salinity, but most substances seem to have overlapping ranges of toxicity to freshwater and saltwater organisms. However, because these two kinds of organisms rarely inhabit the same body of water simultaneously, separate criteria were derived for each. Even though these two kinds of organisms are physiologically different, they do not seem to be too different toxicologically. Bioconcentration factors and acute-chronic ratios seem to be fairly similar for many freshwater and saltwater species for many pollutants, particularly organic chemicals.

46. Comment—The Guidelines base the criteria only on sensitive species and do not take into account insensitive species.

Response—The Guidelines do not necessarily base the criteria on the data for the most sensitive species. However, an aquatic ecosystem cannot be protected by protecting only the species which are insensitive. Protecting half the species will probably not protect the community. To offer reasonable protection to aquatic life and its uses, each major kind of organism and each major use must be given reasonable protection. In some cases it may in fact be necessary to protect the most sensitive species if it is a highly desirable species.

47. Comment—Species should be tested at their environmental extremes.

Response—Toxicity tests with each pollutant could indeeed be conducted with some or all species under a variety of extreme conditions and the lowest result obtained with a species could be used instead of a mean result. On the other hand, differences between results with different species seem to be much greater, and therefore more important, than the differences between results obtained with one species under different conditions. Furthermore, criteria need not necessarily protect species from all stress under the most extreme conditions, because aquatic communities and populations of individual species can recover from some perturbations.

48. Comment—Only data for species that are widely distributed, representative, critical, indigenous, important, ecologically relevant and sensitive should be used.

Response—Few species would satisfy all of the requirements that have been suggested. As more and more data are obtained with a wider variety of species for any one pollutant, it becomes more obvious that few if any species are atypically sensitive, although that may not be true for aquatic communities which contain very few species. No data exist to show that species in any one key role are toxicologically more sensitive than other kinds of species. Ecologically relevant species and species that have key roles or are relevant to the overall functioning of viable ecosystems are not necessarily toxicologically different from other species. EPA feels that if the available data cover an adequate number and variety of species, it is not necessary to try to identify and conduct tests with all important, sensitive species. In addition, the derivation of a criterion should not be based only on sensitive species, because a knowledge of the range of sensitivities may be useful. For instance, elevated concentrations of a pollutant that produces a narow range of species sensitivities are likely to cause more damage than elevated concentrations of a pollutant that produces a wide range of species sensitivities.

49. Comment—The distinction between ionizable and unionizable compounds is not very good because some chemicals ionize and reach chemical equilibrium very slowly and others very rapidly.

Response—Most chemicals can readily be classified into one of three groups:

A. Chemicals that ionize, including hydrolyze, at least 90% and reach 90% of equilibrium in less than 8 hours in most surface waters.

B. Chemicals that ionize, including hydrolyze, less than 10% in 30 days in most surface waters.

C. Chemicals that do not fit into either one of the above categories.

For the purpose of the Guidelines, chemicals in the A group should be considered ionizable, chemicals in the B group should be considered non-ionizable, and chemicals in the C group should be classified on a case-by-case basis. Although the distinction between ionizable and unionizable may not be perfect, it is very useful for most chemicals.

50. Comment—Each individual organic compound should be considered separately.

Response—The vast majority of organic chemicals will be considered separately according to the Guidelines except for structurally similar organic compounds that meet all three specifications given in the Guidelines, such as polychlorinated biphenyls and toxaphene.

51. Comment—In-stream water quality criteria are meaningless for substances that are highly insoluble.

Response—The concentration of some substances in sediment may be important separate from the concentration of the substance in the ambient water and for these compounds a sediment quality criterion may be necessary. Generally such compounds can also cause adverse effects if the concentration in the ambient water is too high even if the concentration in the sediment is low. Thus for such compounds both kinds of criteria may be necessary rather than just one or the other.

52. Comment—If a substance is not dissolved, it is not biologically or toxicologically available.

Response—Although this may usually be true, it certainly does not apply to elemental mercury which can be oxidized and methylated to form a very toxic compound. Some organic acids and phenols and hydroxide and carbonate salts of metals have solubilities which differ substantially from one body of water to another.

53. Comment—Criteria for metals should not be for total metal.

Response—Criteria for metals will generally not be based on total metal. Most will be based on total recoverable metal because forms of metals that are not measured in the total recoverable procedure probably are not, and will not become, toxic. A major problem is that some people use a procedure for total recorverable, but report the results as total, metal. In many situations the two results are about the same, but in some cases the results are quite different.

54. Comment—The Guidelines should give more guidance for distinguishing between acceptable and unacceptable data.

Response—The Guidelines contain as much detail on this subject as EPA believes is currently feasible. Items such as the maximum acceptable control mortality and minimum number of test organisms are based on what many aquatic toxicologists generally feel are acceptable, as expressed in published methods. No data should be used in the derivation of a criteria until their quality and acceptability had been reviewed by a competent person. Competent people will occasionally disagree, but that is a fundamental property of subjective decisions.

55. Comment—Only published data should be used.

Response—Peer review is one of many concepts that is better in theory than in practice. Some poor quality data are published and some high quality data are rejected. In addition, publication is not a particularly rapid process. Whether or not data are used should depend on the applicability and quality of the data, not on whether they have been published. Data that are not published should be made readily available if they are used to derive water quality criteria.

56. Comment—All static test are unacceptable

Response—In general, high quality flow-through acute tests are preferable to high quality static acute tests, but static tests are by no means unacceptable. Few data are available to show whether static tests consistently produce acute values lower or higher or different than flow-through tests. Whereas degradation, violatilization, and buildup of metabolic products are more likely to be a problem in static tests, operator and mechanical errors are more likely in flow-through tests. Static acute tests are certainly not unacceptable for most pollutants, but static chronic tests generally are unacceptable because of changes in the toxicant concentrations and the quality of the dilution water during the test.

57. Comment—Data obtained using test organisms that were previously exposed to the pollutant should be used.

Response—Comparisons of results obtained with unexposed and previously exposed organisms should indicate whether or not acclimation has occurred. Generally, data obtained with acclimated organisms should not be used in deriving criteria because acclimated organisms are the exception rather than the norm. Rarely, if ever, can acclimation be depended on to protect organisms in a field situation because concentrations often fluctuate and motile organisms do not stay in one location very long. Data obtained with acclimated organisms may be acceptable for use in deriving some site-specific criteria.

58. Comment—Foreign species should be used to expand the data base.

Response—Foreign species may be representative of indigenous species, but some of them are quite unusual. Data obtained with foreign species may give good indications of indigenous speceis that should be used in tests on some pollutants and may identify some potential problems that should be investigated.

59. Comment—If data for brine shrimp are not used, the criteria should not apply to saline waters.

Response—Data obtained using brine shrimp are not used because these organisms are atypical. Although they may not be usually sensitive or insensitive to various pollutants, the species found in North America and used for testing only survive in the Great Salt Lake and in salt ponds near San Francisco Bay. These two habitats are unlike any others in the United States. If criteria were to be derived specifically for the Great Salt Lake or for salt ponds, then data for brine shrimp should be used.

60. Comment—Structure-activity relationships should not be used unless proven.

Response—No provision is made in the Guidelines for the use of structure-activity relationships. Such relationships may soon be well enough understood that they can be used in deriving water quality criteria.

61. Comment—A criterion should not be derived for a pollutant until data are available for a broad range of commercially, recreationally, and ecologically important species. Each species should be acutely and chronically tested under a variety of conditions in a number of different waters.

Response—Except for those people who merely want to stop EPA from deriving any water quality criteria, most people will admit that there must be some reasonable limit as to how much information is necessary concerning any regulatory action. This is as true for deriving water quality criteria, as it is for issuing NPDES permits, submitting PMNs, registering pesticides, etc. All of these regulatory activities deal with potentially significant adverse effects on aquatic organisms and should take into account many of the same possible kinds of adverse effects. Therefore, the data needs for these various activities should probably be somewhat similar, but for each regulatory activity the minimum data requirements also need to take into account the special aspects of the program and practical considerations. Unrealistic data requirements will benefit no one. It is not necessary that all questions be answered before any action is taken. It is only necessary that enough data be available to allow reasonable confidence that the water quality criteria will generally not be too high or too low.

EPA has developed minimum data requirements that describe the amounts and kinds of information that should usually be available if a criterion is to be derived using the Guidelines. When the minimum data requirements are satisfied, it should usually be possible to derive a useful criterion. The requirements take into account many things such as:

a. The existence of some species which are commerically or recreationally important and generally sensitive to some broad classes of pollutants;

b. The range of species for which data are available;

c. The cost of obtaining additional data and the usefulness of the data; and

d. The reasonableness of extrapolations from one species to another within and between groups.

The requirements set forth in the minimum data base are indeed minimal, considering the great varitey of species which exist in most aquatic ecosystems. However, EPA feels that based on the availavble information the routine requirement of more data would probably not improve criteria enough to justify the additional cost.

62. Comment—The mimimum data requirements should depend on the nature of the pollutant.

Response—EPA feels that such an approach may be feasible some time in the future, but would be an unwarrented level of sophistication at this time. For a few pollutants, it may be possible to relax some of the data requirements, but in general this can only be determined after enough data are available to indicate that a special case exists. In other cases the minimum data may indicate that additional data are highly desirable.

63. Comment—Criteria should not be derived if enough data are not available. The alternative procedures which were proposed should not be used.

Response—EPA agrees that a numerical criterion should not be derived if enough appropriate data are not available, except in some special cases. EPA also agrees that the alternative procedures which were proposed should not be used to develop numerical criteria at the present time. However, EPA feels that when a numerical criterion is not derived, a descriptive criterion can be used to accurately reflect the latest scientific knowledge.

64. Comment—The guidelines should give more guidance on relating a criterion to a water quality characteristic.

Response—More detail on this subject has been written into the Guidelines.

65. Comment—If data on the relation of toxicity and water quality are not available, no criterion should be derived.

Response—The purpose of a criterion is to present the best available information, not to ensure that all desirable information is available. Any water quality characteristic may affect the toxicity of each pollutant to some degree and it is never going to be possible to investigate all such interactions for even a few species and pollutants. EPA has adopted a minimum data base requirement for deriving a criterion, but there must be practical limits or no criterion will ever be possible. When the minimum data base requirements are satisfied, a criterion should be derived regardless of speculation that some unstudied relationship exist. When enough good data demonstrate a relation between toxicity and a water quality characteristic, an attempt should be made to use this information in the derivation of a criterion. A major purpose of site-specific criteria is to take into account the effect of local water quality conditions on toxicity.

66. Comment—Do not specify the form that a relationship between toxicity and water quality must take.

Response—The Guidelines allow the use of any set of transformations that fit the data well. The log-log model is given as an example because it seems to fit most of the available data concerning the relationship between hardness and toxicity of metals (the only such relationship for which much quantitative data are available) reasonably well.

67. Comment—The toxicity of metals should not be related to "hardness".

Response—EPA has tried to derive criteria in a form that will (a) adequately protect aquatic organisms and (b) be practically useful. Hardness is used as an easily measured surrogate for a number of interrelated water quality characteristics, such as pH, alkalinity, calcium, and magnesium. Various combinations of these probably affect individual metals differently, but these are all reasonably well correlated with hardness in a wide variety of natural waters. Some waters, such as those impacted by acid mine drainage, obviously are special cases, but they have special problems of their own.

68. Comment—Do not extrapolate slopes for toxicity vs. water quality from fish to invertebrates or from acute values to chronic values.

Response—The Guidelines do not now assume that the acute slope and the chronic slope are similar for a pollutant. On the other hand, there is no reason to believe that invertebrates are more similar than are fish and invertebrates. As explained earlier, the group "invertebrates" does not consist of a collection of species that are similar taxonomically or toxicologically. Some water quality characteristics apparently affect the toxicity of the pollutant, rather than the sensitivity of the organisms. For these kinds of factors, slopes should be the same for different species. Even factors that affect such things as the permeability of membranes may produce similar slopes for a wide variety of species. If each species must be treated separately, no criteria will ever be possible.

69. Comment—Relationships based on only two points should not be used.

Response—Two points certainly do not provide very much information about the shape, slope and position of a line. However, if other information or a reasonable assumption is available concerning the shape of the line, two good data points, spaced at a reasonable interval, can provide very useful information concerning the slope and position of the line. Three appropriately spaced points would certainly be better, and four points would be an ideal minimum.

70. Comment—Do not combine relationships that are and are not statistically significant.

Response—The Guidelines do now specify that relationships should be tested for statistical signficance. A test for statistical significance may be one indication of whether or not a slope is useful, but such a test cannot be used with just two points and does not take into account such things as the comparability of the data, the quality of the test, and the range of the independent variable. A relationship based on six points may not be as significant as it seems if five of the points are tightly grouped.

71. Comment—The Guidelines should not combine 96-hr LC50 values and 48-hr EC50 values.

Response—Both LC50 values and EC50 values are used to measure acute toxicity of a substance to aquatic organisms. In general, an EC50 can be based on a wide variety of effects, but the Guidelines specify that the only effects to be used for deriving criteria are incomplete shell development, immobilization, and loss of equilibrium. All of these are certainly drastic effects. In a field situation these effects probably often lead to death. Just as the endpoint may be specific for the species, so may be the length of the test. The generally accepted length of an acute test with daphnids is 48 hours, whereas for most species of fish, it is 96 hours. Thus the Guidelines use both 48-hr EC50 values and 96-hr LC50 values because they are the widely accepted durations and endpoints used to measure acute toxicity to specific species.

72. Comment—Shell deposition tests are chronic tests and should not be equated with lethality tests.

Response—"Acute" implies "short" not "death". Many acute toxicity tests do use death for the effect, but many also use non-lethal effects. The shell deposition test is one of many non-lethal acute tests and is generally accepted as a short test compared to the average life span of oysters.

73. Comment—Adjustment factors should not be used to adjust for the length of the test, the technique, and unmeasured concentrations.

Response—All three kinds of adjustment factors have been deleted from the Guidelines. The factor for the length of the test was found to be unnecessary because most tests had been conducted for the standard times usually specified for the individual species. Thus the Guidelines now specify that only data from tests conducted for the time specified for the species should be used to calculate the Final Acute Value.

EPA has found that on the average flow-through acute tests give results slightly lower than do static tests, but the relationship does not seem to be too consistent and may vary from species to species for some pollutants. In addition, on the average results based on measured concerntrations do not seem to be much different from those based on unmeasured concentrations.

However, the results of flow-through tests based on measured concentrations are generally accepted as being better measures of acute toxicity than the results of flow-through tests based on unmeasured concentrations or the results of any static or renewal tests. Therefore, whenever the results of flow-through acute tests in which the concentrations were measured are available, the results of all other kinds of acute tests with that species and pollutant are not used in the calculation of the species mean acute value.

74. Comment—Species sensitivity factors should be pollutant-specific; and average factor should not be calculated for a variety of substances.

Response—EPA agrees. The requirement for acute values for at least eight different species was developed in part to allow for a reasonably good calculation of a mean acute value and a species sensitivity factor for each individual pollutant. A better way of using the acute values for the individual species has been developed, but no extrapolations are made from one pollutant to another.

75. Comment—The distribution of species mean acute values for a pollutant will be truncated if the species cannot be killed or affected by concentrations above solubility.

Response—Some species are so resistant to some pollutants that they cannot be killed or affected in acute tests even by concentrations which are much above solubility. Such "greater than" values cannot be used in the calculation of means and variances for pollutants. When the "greater than" values are for insensitive species and are at or above solubility, the values can be used in the calculation of the Final Acute Value by adjusting the cumulative proportions for all the speices with quantitative values. The shape of the curve at the high end cannot be determined, but the Final Acute Value is more dependent on the species mean acute values and the cumulative probabilities at the low end.

76. Comment—Early life-stage tests with fish should be used interchangeably with life-cycle and partial life-cycle tests with fish.

Response—EPA agrees that early life-stage tests with fish generally give about the same results as comparable life-cycle and partial life-cycle tests. However, because the shorter test is merely a predictor of the longer tests, whenever both kinds of results are available, the results of life-cycle and partial life-cycle tests should be used instead of the results of early life-stage tests.

77. Comment—Appropriate measures of chronic toxicity and appropriate lengths of exposure should be defined.

Response—The descriptions of appropriate chronic tests have been clarified.

78. Comment—The factor of 0.44 should not be used.

Response—It is not now used.

79. Comment—The Final Chronic Value should not be lower than the lowest measured species chronic value, even if chronic data are not available for sensitive species.

Response—Aquatic ecosystems cannot be protected from chronic toxicity by protecting only the insensitive species from chronic toxicity. In the past both arbitrary and experimentally determined application factors have been used to relate acute and chronic toxicity. For a variety of reasons the Guidelines do not use an application factor, but instead use the acute-chronic ratio, which is similar to the inverse of an application factor. Thus the acute-chronic ratio should normally be greater than one. The acute-chronic ratio is to be used with invertebrates as well as fish and is to be an experimentally determined value for each individual pollutant. The acute-chronic ratio should also avoid the confusion as to whether a large application factor is one that is close to unity or one that has a denominator that is much larger than the numerator. The acute-chronic ratio is calculated by dividing the appropriate measure of acute toxicity for the species (as specified in the Guidelines) by the appropriate measure of chronic toxicity for the same species (as specified in the Guidelines).

Some people have confused application factors and safety factors and use of the term "acute-chronic ratio" should help avoid this problem. Acute-chronic ratios are a way of estimating the chronic sensitivity of a species for which no chronic toxicity data are available. Safety factors would provide an extra margin of safety beyond the sensitivity of the species. Safety or uncertainty factors are intended to reduce the possibility of underprotection, whereas acute-chronic ratios are intended to estimate the actual chronic sensitivity of the species to the pollutant. This estimate is just as likely to be too high as it is to be too low. A mean acute-chronic ratio will in fact be too high for half the species and too low for the other half.

When three or more acute-chronic ratios have been determined for a pollutant with both fish and invertebrates, three patterns have been observed when the individual species are listed in order of their species mean acute values:

a. The ratios randomly differ by a factor of ten or more.

b. The ratio appears to be about the same (within a factor of ten) for all species.

c. Species with higher acute values also have higher acute-chronic ratios.

The available data indicate that fish and invertebrates do not consistently have different acute-chronic ratios and that for some pollutants freshwater and saltwater species have similar acute-chronic ratios.

80. Comment—No application factor should be used unless it is specific for the pollutant, species, and water.

Response—There is no point in using an application factor or acute-chronic ratio or any concept if it does not allow some generalization or extrapolation from one species to another or from one water to another. Not allowing any generalizations or extrapolations would require that much data be generated for each species and each pollutant in each water in which a criterion is necessary. When enough supporting data are available, extrapolations using such things as acute-chronic ratios are cost-effective and scientifically sound.

81. Comment—Additional development of methodology for toxicity tests with aquatic plants is needed.

Response—This is most certainly true. Much other research also is needed, and generally is considered higher priority. EPA hopes that someday all of the additional research that needs to be done will be done. Few pollutants seem to affect aquatic plants at concentrations which do not chronically affect aquatic animals, and it is hoped that this is not an artifact of the test methods currently used.

82. Comment—Data on toxicity to plants should not be used for deriving criteria because plants are more site-specific than animals.

Response—Numerous species of plants, especially algae, exist in most bodies of water. On the other hand, EPA knows of no data to support the contention that the sensitivities of aquatic plants are any more site-specific than those of aquatic animals, or that the range of sensitivities between plants is as great as that for animals. One species may or may not be representative of other species. After the methodology for toxicity tests with aquatic plants is better developed, tests with a wider variety of species would certainly be desirable.

83. Comment—The Final Plant Value should not be the lowest available plant value based on measured concentrations.

Response—EPA adopted the procedure described in the Guidelines for obtaining the Final Plant Value for several reasons including:

a. The methodology for toxicity tests with aquatic plants is not well developed.

b. For only a few pollutants have toxicity tests been conducted with more than a very few species of plants.

c. Little is known about the range of sensitivities of various species of aquatic plants.

d. Based on available data, almost no pollutants are toxic to aquatic plants at the lowest concentrations which are chronically toxic to aquatic animals or cause unacceptable residues.

84. Comment—Residue accumulation in any part of an aquatic ecosystem should be prevented as much as possible.

Response—Accumulation of residues in aquatic organisms only becomes a problem if the concentration of residue is high enough to adversely affect either (a) the organism itself, (b) a consumer of the organism, or (c) the marketability of the organism. Adverse effects on the aquatic organism itself will be detected in acute and chronic toxicity tests. The use of FDA action levels and chronic feeding studies with wildlife are designed to protect the uses and consumers of aquatic organisms.

85. Comment—Bioconcentration factors (BCFs) derived from field data should not be used.

Response—EPA feels that BCFs derived from adequate data, whether they be laboratory data or field data, should be used. More data are necessary to document a BCF from a field exposure than a laboratory exposure, as specified in the Guidelines, but if enough data are available, field BCFs should be used.

86. Comment—Kinetically derived bioconcentration factors (BCFs) should be used.

Response—Kinetically derived BCFs should be used if the bioconcentration test lasted long enough, *i.e.*, to apparent steady-state, to verify that the model (assumptions) used in the calculations actually fits the data for the individual pollutant.

87. Comment—Bioconcentration factors (BCFs) should not be estimated from octanol-water partition coefficients.

Response—The available data seem to indicate a reasonably good relationship for lipid-soluble substances between steady-state BCFs and octanol-water partition coefficients. BCFs estimated from partition coefficients are not used in the Guidelines because measured BCFs are available for all pollutants for which a maximum permissible tissue concentration is available.

88. Comment—Bioconcentration factors (BCFs) are dependent on temperature, food, salinity, stress, and other things.

Response—Many things such as these probably do affect BCFs. Until data are available to show that such effects are important and are not species-specific, little needs to be, or can be, done to take such factors into account when deriving water quality criteria.

89. Comment—Bioconcentration factors (BCFs) should be based only on tissues that are actually eaten.

Response—Although people usually only eat muscle tissue of fish, wildlife usually eat the whole body of fish. The tissues used in the determination of BCFs must be appropriate to the kind of consumer organism or regulatory action. On the other hand, since the BCF for a lipid-soluble substance seems to be proportional to percent lipids, extrapolations can be made on the basis of percent lipids regardless of the tissue.

90. Comment—Chronic toxicity tests with rats and mice should not be used as representative of tests on mammalian wildlife.

Response—Because results of tests on a variety of species are extrapolated to man, it should be just as reasonable to extrapolate from one mammalian species to another mammalian species within certain limits. However, such extrapolations are not now used in the Guidelines; only the results of chronic toxicity tests with wildlife are used to protect wildlife consumers of aquatic life.

91. Comment—Information concerning bioconcentration should only be used if such information is used to protect aquatic organisms, not to protect the marketability of aquatic organisms.

Response—Protection of aquatic organisms must include not only the protection of the existence of aquatic organisms, but also protection of the common uses of aquatic organisms. Commercially important aquatic organisms cannot be considered adequately protected if they cannot be sold. The Guidelines do not use any data pertaining to safety to humans in an attempt to protect human consumers of aquatic organisms. Instead, the Guidelines merely attempt to ensure that residues in aquatic organisms do not exceed FDA action levels so that the uses of commercially and recreationally important species are not restricted by the Food and Drug Administration.

92. Comment—A Final Residue Value calculated from an FDA action level is actually a concentration that will result in the average concentration in some species being at the FDA action level.

Response—This is a good point. A similar situation exists when the calculation is based on a concentration which caused an adverse effect in a chronic wildlife feeding study. In all such cases, the Final Residue Value should be lower, but EPA knows of no non-arbitrary way to determine how much lower the value should be.

93. Comment—The FDA action levels for finished animal feed should not be used.

Response—They are not now used.

94. Comment—Flavor impairment should not be used to derive water quality criteria for aquatic life.

Response—Many of the commercially and recreationally important aquatic orgnaisms are consumted by people. If the flavor is significantly impaired, the use of these species will be adversely affected. Flavor impairment should be considered an effect that can adversely affect the use of aquatic organisms.

95. Comment—The instructions for using the other data are not very detailed and are not mathematical.

Response—EPA has tried to include as much detail in the instructions for using the other data as are currently justified. Extensive detail and mathematical treatment are not deemed realistic at this time because so little information is available concerning the various kinds of other data.

96. Comment—The final review of the criteria should allow revision up or down based on sound scientific evidence.

Response—The Guidelines always have allowed revision up or down, but this is now stated explicitly in the Guidelines.

97. Comment—Some bodies of water, such as some USGS benchmark streams and the Houston ship channel, contain concentrations above the criteria for some pollutants and still contain aquatic communities that are diverse, healthy, and productive. Such information should be used in the review of the criteria because it indicates that some criteria are too low.

Response—Rarely are there enough data available to accurately identify the concentrations of pollutants to which aquatic organisms in bodies of water are actually exposed. The sampling scheme should provide a good estimate of the mean and variance of the concentration; a few grab or composite samples cannot provide enough information to characterize the concentrations of pollutants in most bodies of water. The concentrations vary not only with time but also with location at each time, so the samples must be taken where the organisms of interest are located at that time.

A more serious problem concerns the definition of an acceptable aquatic ecosystem. How does one determine if an aquatic ecosystem is healthy or productive? If a diverse system is, by definition, healthy, is it also, by definition, productive? What is the minimum acceptable diversity? What is the minimum acceptable productivity? Should the acceptable levels of diversity and productivity be site-specific? Is a body of water acceptable just because no dead fish are observed. How many pounds of trout should a trout stream produce each year to be considered healthy and productive? How does one treat motile species that may avoid some periodic increases in pollution levels? Is an aquatic ecosystem healthy and productive if the normally edible portion of a consumed species tastes bad or contains excessive residues? Questions such as these indicate the difficulty of quantitatively judging the quality of aquatic ecosystems on the basis of their acceptability or usefulness to man or on any other basis. Although judging bodies of water would be a difficult job, it certainly could be done by a competent group of trained professionals. The point is that it is not as easy a job as some people would like to think. There are also people who feel that various pristine bodies of water should be managed because they are not as productive as they could be.

As mentioned earlier, the criteria documents derive criteria which may be too high or too low for some specific bodies of water. With appropriate modifications the Guidelines can be used to derive criteria for any specific body of water or geographic area. In addition, it is certainly possible that one or more factors which affect the toxicity of one or more pollutants may not have been studied very throughly or even identified yet. The criteria are based on the best available information and the state-of-the-art of aquatic toxicology, but it is always possible that something important has not been adequately studied by regulators, discharges or academia.

Appendix E.—Responses to Public Comments on the Human Health Effects Methodology for Deriving Ambient Water Quality Criteria

I. Introduction

On March 15, 1979, the U.S. Environmental Protection Agency (EPA) announced the availability for public comment of the proposed methodology for the derivation of ambient water quality criteria for the protection of human health. The public comments were resolved in three phases.

First, comments relating to policy issues were resolved in an initial screening/disposition by Agency personnel. Second, a peer review workshop was conducted and involved Agency personnel, contractors, and recognized scientists. The group evaluated all issues pertaining to the derivation of criteria for non-carcinogens, and third, a similar workshop was held to review all issues relating to the derivation of criteria for carcinogens.

The following report presents the resolutions of the public comments by the EPA after considering the advice of the meeting attendees. While the EPA greatly appreciates the contribution of these individuals and acknowledges their substantial assistance in resolving many difficult questions, the EPA accepts full responsibility for the positions outlined in this document. (Note: Comments addressing similar issues were appropriately compiled and summarized under each issue.)

Comments Resolved in Initial Screening

Issue 1

Comment summary: The water quality criteria documents should provide information and/or guidelines for deriving standards from criteria.

Response: The water quality criteria documents contain information which will be useful in developing standards (e.g., current levels of exposure). However, in developing standards, many additional factors not directly related to criteria must be considered. It would be more appropriate to compile and to analyze this information as part of the standard-setting process rather than to include it in the criteria documents. Guidelines will be issued separately since the development of the standard includes use designation with a commensurate criteria value.

Issue 2

Comment summary: Water quality criteria should consider or be limited by technological achievability, cost/benefit analysis, limits of detection, and environmental fate.

Response: The distinction between criteria and standards must be recognized. For non-carcinogens, ambient water quality criteria are estimates of concentrations in water which will not result in either adverse human health effects (criteria based on toxicity) or unpleasant taste or odor (organoleptic criteria). For carcinogens, criteria are estimates of concentrations of individual compounds in water which will result in specified increases in the lifetime risk of developing cancer. By definition, these criteria exclude considerations of technological achievability, cost/benefit analysis, limits of detection, and environmental fate, as appropriate within the authority of The Clean Water Act [33 U.S.C. 1314(a)]. These factors are more properly considered in the standard-setting process.

Issue 3

Comment summary: The validity of a single criteria for all bodies of water is questionable. Criteria should be site specific an/or use specific.

Response: In the standard-setting process, criteria may be modified based upon site specific or use specific considerations.

Issue 4

Comment summary: Even if there is insufficient data, some criteria must still be developed for "highly hazardous compounds."

Response: If there is sufficient information to indicate that a compound is "highly hazardous," there should be sufficient information to derive a criteria. Conversely, if insufficient data are available, by definition no criteria can be derived.

Issue 5

Comment summary: Criteria should be derived only for persistent compounds or for compounds which present a clear hazard to humans.

Response: Criteria can be derived for any compound on which sufficient information is available. By definition, criteria are independent of persistence or current levels of exposure.

Issue 6

Comment summary: Criteria should be developed to protect terrestrial wildlife as well as humans and aquatic organisms.

Response: Because of the great number of diverse wildlife species and differences in their habitat, diet, and behavior, it is unlikely that a single criteria could be developed to protect all wildlife species from a given contaminant. The EPA is currently assessing possible approaches to developing a valid methodology for deriving wildlife criteria. Until a specific wildlife criteria methodology is developed, the proposed aquatic life and human health effects criteria should serve as interim levels for the protection of wildlife.

Issue 7

Comment summary: Criteria should be derived by an independent scientific panel and not by the EPA.

Response: The EPA has a legislative mandate to derive ambient water quality criteria and must accept the final responsibility for this process. However, the EPA has solicited the advice of many independent scientists in this effort. It should be noted that the consensus of the peer review committees has been considered and generally followed by the EPA. Nonetheless, the responsibility for the criteria rests solely with the Agency.

Issue 8

Comment summary: The ambient water quality criteria are not sufficiently protective of special groups at risk.

Response: In most cases, each document contains a specific section on special groups at risk. This is intended to serve as a notice to individuals or agencies using the criteria; that the derived criteria may not be sufficiently protective in all applications. If sufficient data are available, information in the section on special groups at risk could be used to modify the criteria during the standard-setting process.

Issue 9

Comment summary: Comments express concern with the failure of the criteria to specifically address possible toxicant interactions.

Response: The importance of toxicant interactions in the environment cannot be disregarded. Each document attempts to summarize the available data on such interactions. However, since the composition of toxicants is likely to vary substantially in different areas, a general approach modifying criteria based upon toxicant interactions is not available at this time. Further, the limitations of valid approaches for dealing with interactions in multi-toxicant mixtures should be recognized.

Issue 10

Comment summary: Because of the uncertainties involved in deriving criteria, the criteria should be limited to only one significant figure.

Response: The number of significant figures used to express the criteria is an admittedly arbitrary decision. The EPA recognizes the inexactitude of these numbers.

III. Comments on Non-Carcinogens

A. Criteria for Chemical Classes

Issue 1

Comment summary: Two basic approaches were taken in the documents on chemical classes when sufficient data were not available on all members in a class:

(a) Criteria were derived for individual chemicals on which sufficient data were available and no criteria were recommended for other chemicals in the class.

(b) A criteria was derived for all or some chemicals in the class based on toxicity data on one or a few members of the class.

Alternative "a" can be criticized for "allowing" contamination by "probably hazardous compounds" (reasoning by chemical analogy). Alternative "b" can be criticized for applying a general criteria to a specific compound for which data are not available.

What guidelines with justifications can be given for selecting either alternative? What other alternatives might be considered?

Response: The initial methodology did not adequately address the problems associated with deriving class criteria. The following section has been added to the methodology and serves as a useful guide in the criteria derivation process.

A chemical class is broadly defined as any group of compounds which are considered in a single risk assessment document. In criteria derivation, isomers are regarded as a chemical class rather than as a single compound. A class criteria is an estimate of risk/safety which applies to more than one member of a class, and involves varying degrees of extrapolation from available data on some members of the class to other class members on which sufficient data are not available to derive a compound-specific criteria (i.e., a criteria based on data solely on the specific chemical for which the criteria is derived).

A class criteria usually applies to each member within the class rather than to the sum of the compounds within the class. While the potential hazards of multiple toxicant exposure are not to be minimized, a criteria, by definition, most often applies to an individual compound. Exceptions may be made of complex mixtures which are produced, released, and toxicologically tested as mixtures (e.g., toxaphene and PCBs). For such exceptions, some attempt should be made to assess the effects of environmental partitioning different patterns of environmental transport and degradation on the validity of the criteria. If these effects cannot be assessed, an appropriate statement of uncertainty should accompany the criteria.

Because relatively minor structural changes within a class of compounds can have pronounced effects on their biological activities, class criteria should be avoided. Whenever sufficient toxicologic data are available on a chemical within a class, a compound specific criteria for that chemical should be developed. Nonetheless, for some chemical classes, scientific judgment may suggest a sufficient degree of similarity among chemicals within a class to justify a class criteria applicable to some or all members within a class. Such a judgment should be influenced by a perceived risk to the human population if a class criteria was not derived.

The development of a class criteria should take into consideration the following:

(a) A detailed review of the chemical and physical properties of chemicals within the group should be available. A close relationship within the class with respect to chemical activity would suggest a similar potential to reach common biological sites within tissues. Likewise, similar lipid solubilities would suggest the possibility of comparable absorption and tissue distribution.

(b) The amount of qualitative and quantitative data for chemicals within the group should be examined. Obviously adequate toxicological data on a number of compounds within a group would provide a more reasonable basis for extrapolation than minimal data on one or two chemicals within a group.

(c) Similarities in the nature of the toxicological response to chemicals in the class provides additional support for the prediction that the response to other members of the class may be similar. In contrast, where the biological response has been shown to differ markedly on a qualitative and quantitative basis for chemicals within a class, extrapolation of a criteria to other members of that class may not be appropriate.

(d) Additional support for the validity of extrapolation of a criteria to other members of a class could be provided by evidence of similar metabolic and pharmacokinetic data, if available, for some members of the class.

Based on the above considerations, it may be reasonable to divide a chemical class into various subclasses. Such divisions could be based on biological endpoints (e.g., carcinogens/non-carcinogens), potency, and/or sufficiency of data (e.g., a criteria for some members of a class but no criterion for others). While no *a priori* limits can be placed on the extent of subclassification, each must be explicitly justified by the available data.

Class criteria, if properly derived and supported, can constitute valid scientific assessments of potential risk/safety and can be used in establishing appropriate standards. Conversely, the development of a class criteria from an insufficient data base can lead to serious errors in underestimating or overestimating risk/safety and should be rigorously avoided. Although scientific judgment has a proper if not totally explicable role in the development of class criteria, such criteria will be useful and defensible only if they are based on adequate data and scientific reasoning rather than intuition. The lack of data on dissimilarity cannot be used as the basis of a class criteria. Further, the definition of sufficient data on similarities in physical, chemical, pharmacokinetic, or toxicologic properties to justify a class criteria may vary remarkably depending on the degree of superficial structural similarity and the gravity of the perceived risk. Consequently, it is imperative that the criterion derivation section of each document in which a class criterion is recommended explicitly address each of the key issues discussed above and define, as clearly as possible, the limitations of the proposed criteria and the type of data necessary to generate a compound-specific criterion.

Class criteria should be corrected when sufficient data become available to derive a compound-specific criterion that protects against the biological effect of primary concern. The availability of a good subchroni study would not result necessarily in the abandonment of a class criteria based upon potential carcinogenicity.

The inability to derive a valid class criteria does not and should not preclude regulation of a compound or group of compounds based upon concern for potential human health effects. The failure to recommend a criterion is simply a statement that the degree of concern cannot be quantified from the available data and risk assessment methodology.

Issue 2

Comment summary: To what extent can "guilt by association" be used to derive a cancer-based criteria for a compound which has been tested for carcinogenicity with negative results [e.g., bis(2-chloroisopropyl) ether in the Chloroalkyl Ethers Ambient Water Quality Criteria Document].

Response: As stated in the response to Issue 1, "guilt by association" is only an extremely limited role in criteria derivation process.

B. Organoleptic Criteria

Issue 3

Comment summary: Whenever organoleptic criteria are derived, corresponding toxicity based criteria should be derived if possible.

Response: The Agency agrees. Since organoleptic criteria are not based on toxicologic information and have no direct relationship to potential adverse human health effects, both organoleptic and toxicity based criteria are provided whenever possible.

Issue 4

Comment summary: The quality of organoleptic criteria should be assessed in terms of experimental design and statistical analysis.

Response: The revised methodology recognizes the limitations of most organoleptic data:

> With very few exceptions, the publications which report taste and odor thresholds are cryptic in their descriptions of test methodologies, number of subjects tested, concentration/response relationships, and sensory characteristics at specific concentrations above the threshold. Thus the quality of the data is usually worse than the toxicological data used for the setting of other criteria. Consequently, a clear critical evaluator of the available data on a compound's organoleptic characteristics should appear in the criteria document.

Issue 5

Comment summary: Criteria based on organoleptic properties should not be considered equal to criteria based on toxicologic effects.

Response: The revised methodology makes a clear distinction between organoleptic and toxicity based criteria. The use of the criteria in the regulatory process should reflect an appreciation of this distinction.

C. Naturally Occurring Compounds

Issue 6

Comment summary: Background levels should be defined in terms of the quality of the data base and geographical/seasonal variations.

Response: The documents summarize data on background levels of naturally occurring compounds and include information on seasonal and/or geographical variation when available.

Issue 7

Comment summary: A distinction should be made between natural and anthropogenic background.

Response: An attempt is made, with extreme difficulty, in the exposure section of the documents to differentiate between natural and anthropogenic background. However, background levels cannot be used directly to modify the criteria. By definition, criteria should not consider current levels of exposure but are estimates of safe level or incremental risk level exposures. Background levels, both natural and anthropogenic, should be considered if the criteria are used to promulgate standards.

Issue 8

Comment summary: What is the minimum data base needed to define a compound as essential?

Response: As indicated in the revised methodology, elements will be accepted as essential if the National Academy of Sciences (NAS) Food and Nutrition Board or a comparably qualified group declares them as such. Elements not yet determined to be essential, but for which supportive data on "essentiality" exists, were recommended to be reviewed by a joint EPA/NAS committee.

Issue 9

Comment summary: How can essentiality be used to modify a criteria?

Response: The following additions have been made to the revised methodology in response to this question:

In order to be useful in modifying toxicity/carcinogenicity based criteria, essentiality must be quantified either as a recommended daily allowance (RDA) or minimum daily requirement (MDR). These levels must be compared to estimated daily doses associated with the adverse effect of primary concern. The difference between the RDA or MDR and the daily doses causing a specified risk level for carcinogens or acceptable daily intake (ADI) for non-carcinogens defines the "window" of daily doses from which the criteria should be derived.

Because errors are inherent in defining both essential and maximum tolerable levels, the criteria should be derived from dose levels near the center of such a dose range. The decision to use either the MDR or RDA will be guided by the size of the window and the quality of the essentiality and toxicity estimates.

The modification of criteria by consideration of essentiality must include all routes of exposure. If water is a significant source of the MDR or RDA, the criteria must allow for attainment of essential intake. Conversely, even when essentiality may be attained from non-water sources, standard criteria derivation methods may be adjusted if the derived criterion represents a small fraction of the ADI or MDR. On a case-by-case basis, the modification in the use of the guidelines may include the use of different safety factors for non-carcinogens or other modifications which can be explicitly justified.

D. Use of NOAELs/NOELs

Issue 10

Comment summary: NOELs and related effect terms should be defined more clearly in the methodology.

Response: In the revised methodology, the following additions have been made to clarify the use of these terms:

In developing guidelines for deriving criteria based on non-carcinogenic responses, five types of response levels are considered:

NOEL—No-Observed-Effect-Level
LOEL—Lowest-Observed-Effect-Level
NOAEL—No-Observed-Adverse-Effect-Level
LOAEL—Lowest-Observed-Adverse-Effect-Level
FEL—Frank-Effect-Level

In the above terms, adverse effects are defined as any effect resulting in functional impairment and/or pathological lesions that may affect the performance of the whole organism, or which contributes to a reduced ability to respond to an additional challenge. The word lowest refers to the incidence of the effect in the tested population. It should be noted that LOELs, NOAELs, and LOAELs refer to exposure levels or dosage zones which are experimentally defined by upper and lower exposure levels. NOELs and FELs, however, are not defined at the lower and upper exposure levels, respectively.

Issue 11

Comment summary: Considerations of experimental design should be more explicitly/quantitatively considered in the criteria derivation process.

Response: The development of a rigid system for considering experimental design in criteria derivation would limit the use of scientific judgment. The section of the methodology dealing with the derivation of toxicity based criteria has been extensively revised to allow for the maximum use of scientific judgment in selecting safety factors based on both the quality of the individual study and the weight of the supporting scientific data.

E. Safety or Uncertainty Factors

Issue 12

Comment summary: Can the guidelines for applying safety factors be clarified or developed in greater detail to minimize inconsistencies without impairing scientific judgment?

Response: The following additions have been included in the methodology to allow for the use of greater judgment in the application of safety factors, while also requiring more explicit justification for the use of any uncertainty factor:

The justifications for the various safety factors can become very restrictive if they are not employed with care and judgment. This is the case especially in those instances where the data do not completely fulfill the conditions for one category of uncertainty factor and appear to be intermediate between two categories. Given the uncertainties in the entire process, it is more appropriate to set the operative uncertainty factor at some intermediate value on a logarithmic scale (e.g., 32, being halfway between 10 and 100 on a logarithmic scale). If intermediate values for uncertainty factors are more representative of actual conditions, then they are used.

In the selection of the uncertainty factor approach, "no indication of carcinogenicity" is interpreted as the absence of carcinogenic data from animal studies or human epidemiology. Short-term carcinogenicity screening tests are considered in the criteria documents, and are used in the derivation of numerical criteria and are used to rule out the uncertainty factor approach.

Because of the high degree of judgment involved in the selection of a safety factor, the criteria derivation section of each document must provide a detailed discussion and justification for both the selection of the safety factor and the data for which it is applied. This discussion should reflect a critical review of the total data base. Factors to be considered include: number of animals tested, parameters tested, species tested, quality of controls, dose levels, route, dosing schedules, etc. An effort should be made to differentiate between coherent results which form a toxicologically valid data base and data which may be spurious in nature.

Issue 13

Comment summary: What, if any, safety factor should be used when deriving criteria from a threshold limit value (TLV).

Response: The safety factor used when deriving criteria from a TLV must depend on the quality of the data base on which the TLV is based. considerations of uncertainties involved in extrapolating data from inhalation to oral exposures, and the quality of the additional supporting data.

F. Related NOAEL Issues

Issue 14

Comment summary: Can/should concentration response curves representing a "full range of effects" be used in deriving criteria?

Response: No available system for utilizing concentration response curves in representing a full range of effects for deriving criteria has been developed. If such a system does become available, it will be assessed by the Agency.

Issue 15

Comment summary: When more than one method is available to derive a non-carcinogen criteria (e.g., 2-year chronic, 90-day, TLV), can guidelines be given for selecting the most appropriate method?

Response: As indicated in the revised methodology, criteria can be based on several different types of data (e.g., studies on humans or experimental animals, subchronic or chronic exposure periods, oral or inhalation exposure routes, TLVs or similar standards). Specific guidelines for selecting a particular study or approach have not been recommended because of the many judgmental factors which are involved. As indicated in the methodology, the criteria derivation section must specifically state the reasons for selecting the approach and study used to derive the criteria.

Issue 16

Comment summary: The approach used to derive criteria for non-carcinogens may not adequately address the question of whether children are at greater risk than adults.

Response: When specific data are available on women or children as groups at increased risk, it should be stated in the document and discussed in the criteria derivation section, but should be used to modify the criteria only if sufficient specific data are available. This is a highly judgmental decision which must be made on an individual case.

Issue 17

Comment summary: Criteria based on carcinogenic effects might not be adequate to protect humans from mutagenic, teratogenic, or other toxic effects.

Response: With very few exceptions, criteria based on carcinogenicity are probably protective for other toxic effects. However, alternative criteria can be derived based on non-carcinogenic effects on a case-by-case basis if there is any doubt of the level of protection offered by the cancer based criteria.

G. Alternative Approaches to the Development of Criteria for Non-Carcinogens

Issue 18

Comment summary: Is there a reasonable way to use multiple NOEL/NOAELs to derive criteria?

Response: The revised methodology clearly indicates that all toxicity must be considered in deriving criteria and multiple NOELS/NOAELs are used. A detailed mathematical approach using multiple NOEL/NOAEL data has not been developed or accepted by the scientific community.

Issue 19

Comment summary: Is there a reasonable way to use dose/response data to derive criteria?

Response: Mathematical models for deriving non-cancer based criteria are available. However, they have not gained wide acceptance in human risk assessment. Until various models have been reviewed in greater detail, the Agency uses the current approach, based on that recommended by the National Academy of Sciences, as the most appropriate.

Issue 20

Comment summary: Confidence intervals or a range should be used in deriving criteria.

Response: A workable method for using confidence intervals in deriving non-cancer based criteria has not been developed. Given the many uncertainties involved in this process, the use of confidence intervals could be misleading in simply considering problems in statistical variation without considering problems in species to species conversion. Safety factors are an accepted procedure and are used to consider both problems in statistical variability as well as problems in species to species conversions and individual susceptibility.

H. Exposure

Issue 21

Comment summary: Should non-cancer criteria be based on all sources of exposure because they are derived from estimates of ADIs (acceptable daily intake) which define *total* daily acceptable doses for man?

Response: The methodology has been revised so that estimates of total exposure can be considered in deriving criteria. Estimates of water and fish consumption are used to derive the criteria. However, the criteria levels can be modified by considering all routes of exposure in the standard-setting process. This approach may be particularly desirable because exposure conditions will probably vary markedly on a regional basis.

Issue 22

Comment Summary: If sufficient data are not available on all sources of exposure, can any reasonable assumptions be made to factor in all sources of exposure or can/should an additional "uncertainty" factor be used?

Response: When no reasonable estimate can be made of contributions from non-fish diet and from air, it can be assumed that one-half of the exposure comes from water and fish and one-half comes from other sources. This is equivalent to using an additional safety factor of 2. It is recognized that the inability to quantify all sources of exposure adds an additional element of uncertainty to the criteria.

I. General Issues

Issue 23

Comment Summary: With the exception of recommending "good scientific judgment," can specific guidelines be given for accepting or rejecting a study or set of studies as a data base for criteria derivation?

Response: Specific guidelines cannot be given for accepting or rejecting studies. Scientific judgment must be exercised in view of the magnitude of the total evidence on the chemical or chemicals under consideration. Chronic data and appropriate exposure routes are most desirable.

Issue 24

Comment Summary: Is there a need to individualize the criteria derivation process so that the "nature of the toxic agent and its mechanism of action" can be more explicitly considered? If so, how can this be accomplished?

Response: The criteria derivation process does consider as specifically as possible the nature of the toxic agent and, when known, the mechanism of action.

Issue 25

Comment Summary: Is the Stokinger-Woodward model adequate for converting inhalation dose data to "equivalent oral doses," or should a more sophisticated approach be used?

Response: The derivation of water quality criteria from inhalation data is an admittedly tenuous process. The following guidelines have been added to the methodology:

Estimating equivalencies of dose/response relationships from one route of exposure to another introduces an additional uncertainty in the derivation of criteria. Consequently, whenever possible, ambient water quality criteria should be based on data involving oral exposures. Even with oral data, differences in dosing schedules and vehicles can be problematic. If oral data are insufficient, data from other routes of exposure may be used in deriving water quality criteria.

Inhalation data, including TLVs or similar values, are the most common alternative to oral data. Estimates of equivalent doses can be made on the basis of extensive pharmacokinetic data for oral and inhalation routes, on the basis of measurements of absorption efficiency from ingested or inhaled chemical, or on the basis of comparative excretion data when the metabolic pathways can be established to be equivalent after oral or inhalation dosing. When sufficient pharmacokinetic data are available, the use of accepted pharmacokinetic models provides the most satisfactory approach for dose conversions. However, if the pharmacokinetic data are marginal or of questionable quality, pharmacokinetic modeling is inappropriate and may result in an artifical sense of exactitude.

The Stokinger and Woodward (1958) approach, or similar models which are based on assumptions of breathing rate and absorption efficiency, can be used as alternatives when data are not sufficient to justify pharmacokinetic principles. Consequently, in using the Stokinger and Woodward or related models, the uncertainties inherent in each of the assumptions and the basis of each assumption should be clearly stated in the derivation of the criteria.

The use of data involving other routes of exposure to derive water quality criteria should not be ruled out. However, as with inhalation data, an attempt should be made to use accepted toxicologic and pharmacokinetic principles to estimate equivalent oral doses. If simplifying assumptions are used, their bases and limitations must be clearly specified.

Because of the uncertainties involved in extrapolating from one route of exposure to another and the consequent limitations that this may place on the derived criteria, the decision to disallow such extrapolation and recommend no criterion is highly judgmental and must be made on a case-by-case basis. Such a decision should balance the quantity and quality of the available data against a perceived risk to the human population if no criteria is derived.

Issue 28

Comment Summary: Can/should criteria be qualitatively or quantitatively ranked in terms of their scientific strength of validity? How could such a ranking system be developed?

Response: The Agency is presently assessing the quality of the data base supporting individual criteria. This will eventually result in the development of a ranking system of all the priority pollutants.

IV. Response to Public Comments on Methodology to Derive Water Quality Criteria

The Carcinogen Assessement Group (CAG) and the Environmental Criteria and Assessment Office-Cincinnati (ECAO-Cin.) of the U.S. Environmental Protection Agency (EPA) has reviewed in detail the public comments on EPA's methodology to derive water quality criteria for carcinogens. Since the majority of the comments are concerned with the low-dose extrapolation procedure and since they are closely related to each other, an appendix is presented which summarizes our new procedure to derive water quality criteria and the rationale for selecting the procedure and compares the new with the old procedure. Much of the criticism has been directed toward utilization of the one-hit linear model for estimation of the risk. After considerable input by a peer review of outside scientists, the multistage model developed by Kenneth Crump has been adopted in place of the one-hit model extrapolation. The Appendix describes the new multistage hit model. Further responses to the individual comments are being presented below.

A. The One-Hit Model

Issue 1

Comment summary: Several comments criticize the one-hit model as arbitrary, inappropriate, simplistic, unrealistic, inaccurate, not universally accepted, and/or overly conservative.

Response: The Agency has adopted a new procedure for deriving water quality criteria which is conceptually similar to, but operationally more systematic than the one-hit procedure used previously by the Agency. Although the criteria calculated by the new procedure are not appreciably different than those calculated by the old procedure as demonstrated in the appendix, most of the general criticisms do not apply to the new procedure.

Issue 2

Comment summary: Comments pointed out that the EPA has declined to use the one-hit model under the federal pesticide laws for heptachlor and chlordane.

Response: The commentor is correct that the one-hit model was not used in the chlordane-heptachlor suspension hearings in 1975. However, in the cancellation hearings, which were held after the formation of the Carcinogen Assessment Group and the adoption by the Agency of the Interim Cancer Assessment Guidelines and in the proposed water quality criteria, one-hit extrapolation model was used for risk estimation. In the current final water quality documents the "linearized" multistage model is used; the comparison between these two approaches in the appendix to those comments shows that the chlordane and heptachlor data have the largest upward curvature in the dose-response curve of all the carcinogens in the water quality list. For this reason the new approach reduces the risk for chlordane and heptachlor more than for the other compounds. This example shows how the new extrapolation procedure compensates for the "overly conservative" results of the one-hit approach in cases where the dose-response data is sharply concave upward at low doses.

Issue 3

Comment summary: The EPA's choice of this model because ". . . it gives greater risk estimates than other plausible models" (page 15978 of March 15, **Federal Register**) was criticized as being a policy/political/social statement rather than a scientific defense.

Response: See the appendix for reasons for selecting linear, non-threshold models.

Issue 4

Comment summary: The statement that this model was endorsed by IRLG (1979) was felt to have limited meaning because this document has not yet been reviewed and because the document is merely a reiteration of policy.

Response: The model was not selected on the endorsement of IRLG. See appendix.

Issue 5

Comment summary: In the methodology (page 15978, column 1, first full paragraph of the March 15, **Federal Register**), this model is scientifically defended as being consistent with three basic concepts in chemical carcinogenesis:

a. The Linearity of the Dose-response Curve for Mutagens—This is challenged on the following points:

The shape of the dose response curve in the low dose region cannot be determined.

Not all assay systems give linear dose-response patterns.

Some Ames tests are linear because the liver microsomes are added in a fixed amount and thus ". . . the laws of first order kinetics require a linear response to the variation in concentrations of the test substance as it is mediated by the activator."

b. Chemicals which are Mutagens are Likely to Induce Cancer—This is challenged on the basis that not all mutagens cause cancer.

c. Epidemiology Studies on Radiation, Cigarettes, and Aflatoxin show a Linear Dose-response Pattern—This is challenged on the following points:

Radiation carcinogenicity cannot be applied to chemical carcinogenicity because they act by different mechanisms.

Not all radiation dose-response data is linear.

Smoking data are compounded by difficulties with cocarcinogens and other exposures.

Aflatoxin data rely purely on estimated exposures.

Response: (a) The commentor points out that even in mutagenesis test systems there is a level of mutagenic response that is too small to be detected and that below this level the shape of the dose-response curve cannot be measured. While this is true, the Agency's point is that the mutagenesis data available are fundamentally consistent with a linear no-threshold mechanism of action. Another commentor has misinterpreted the mutagenesis dose-response data. As presented by the original authors, the data show some residual mutagenic activity at zero dose. This is interpreted erroneously as being a threshold below which no response occurs. Another commentor supports the Agency's contention that the mutagenesis dose-response relationship is linear by giving a possible explanation for the linearity.

(b) The fact that chemicals which are mutagenic are "likely" to induce cancers does not imply that "all" mutagens cause cancer. Furthermore, those mutagens which were not shown experimentally to be carcinogenic could not be accepted unequivocally as non-carcinogenic because of the uncertainty in the study outcome.

(c) Both chemicals and radiation cause DNA damage and subsequent interference with the normal functioning of DNA, although the mechanisms for causing this damage are different for radiation and chemicals.

Issue 6

Comment summary: Several comments stated that the possibility of thresholds for at least some chemical carcinogens is not unreasonable, should be addressed in greater detail and/or cannot be resolved at this time. The possibility of assuming a threshold was recommended for the following compounds: chloroform, PCBs, acrylonitrile, hexachlorocyclohexane, chlorinated benzenes, and chlorinated ethanes.

Response: Currently there is no satisfactory method for estimating the low-dose carcinogenic risk to "epigenetic" chemicals. Until the mechanisms for such action are understood on a case-by-case basis to the point of being able to justify a specific extrapolation procedure, the linear, no-threshold concept will be assumed to be valid. The "linearized" multistage approach now used result in lower risks than the older "one-hit" approach for compounds having a sharp upward curvature.

For the specific chemicals referred to in Issue 6, no evidence was presented in support of a carcinogenic threshold dose except for chloroform. Commentors state that chloroform induces an increased rate of cell proliferation, which they implicitly equate with carcinogenesis, at high doses because of a cytotoxic response which is unrelated to direct DNA interaction and which therefore is not expected to occur at low doses. Three pieces of evidence are cited in support of that position: (a) chloroform is not mutagenic in the Ames tests; (b) at doses below 15 mg/kg/day, mice show no excess rate of DNA synthesis in kidney and liver tissue. This excess is expected for a cytotoxic response leading to cell proliferation; (c) Roe et al (1979) on the basis of responses in four strains of mice, has established a no-carcinogenic effect level of 17 mg/kg/day, whereas the positive NCI experiment used by EPA for the water criterion was carried out at 200–400 mg/kg/day.

Before the existence of a threshold for chloroform can be established several issues need to be resolved: (a) are the no-effect levels in the DNA synthesis studies and in Roe's observations real phenomona or only artifacts occurring simply because the limit of detection in these studies was being reached? (b) The relation between the cellular proliferation, which is alleged to be manifested by increased DNA synthesis, and carcinogenesis is unclear, since in the mouse strains used by NCI kidney tumors do not occur and liver tumors do, whereas in the experiments cited by a commentor both liver and kidney exhibit DNA synthesis.

Issue 7

Comment summary: A distinction should be made between genetoxic and epigenetic carcinogens based on mutagenicity data. These comments imply that a threshold model would be more appropriate for epigenetic carcinogens.

Response. While it is true that most carcinogens do interact with DNA, there are some compounds, such as phorbol esters in mouse skin studies and phenobarbital in rat liver, which are incomplete carcinogens by themselves, but require another substance to initiate or promote their action. In these studies the effects are unrelated to DNA interactions and apparently involve important recovery processes. This newly-developing field is not yet well enough understood to justify the use of a particular dose-response extrapolation model.

Issue 8

Comment summary: Another group of comments vigorously opposed the non-threshold assumption used in the one-hit model. Criticism of the non-threshold assumption were most extensively articulated by commentors which contended that the non-threshold assumption is:

Contrary to experience and logic, to what is known of biological systems, and to existing scientific data and is a product of the desire to obtain a simple and easy-to-use method for criteria derivation.

A related comment contended that thresholds are apparent for mutagens and therefore—given the presumed relationship of carcinogenicity to mutagenicity—thresholds should be postulated for carcinogens.

Response: Commentors state that the linear non-threshold model is: (a) contrary to experience and logic; (b) contrary to what is known about biological systems; (c) contrary to existing scientific data and (d) an approach based on faith that could not be disproved by any facts.

(a) The linear non-threshold model does not imply, as suggested by a commentor, either that (a) cancer is inevitable in the general public or in heavily exposed industrial workers or that (b) all substances are carcinogenic. It simply states that the probability of a person getting cancer is proportional to the amount of carcinogen to which he is exposed.

(b) First order reaction processes are common in biological systems especially in mutagenesis.

(c) Dr. Bingham's article did not advocate a sigmoid dose-response curve in preference to a linear curve, as stated by the commentor. She stated that several environmental factors can alter the dose-response relationship, and would thereby change the curve whichever way it was described. In fact, her main point was that "until we understand more about the primary carcinogenic insult and its progression, predicting or estimating thresholds is risky." The Agency agrees with this conclusion.

(d) The Agency agrees that it would be extremely difficult to use negative epidemiology data as proof that a carcinogenic threshold exists for a compound having positive animal results.

Issue 9

Comment summary: Several comments critized the one-hit model because it does not fit some experimental data as well as other models. This was illustrated for heptachlor, chlordane, and aflatoxin and chlorinated ethanes.

Response: The new extrapolation method overcomes the difficulty in fitting the model to the data because the multistage model has enough flexibility to fit any montonically increasing dose-response relationship. See also the response to Issue 16.

Issue 10

Comment summary: The application of the model was also criticized because it disregards data at all but one dose level and fails to consider the results of other experiments.

Response: The new procedure does not have these shortcomings. See appendix.

Issue 11

Comment summary: The highest potency factor to the exclusion of all other data should not be used in generating criteria because this process does not involve maximum-likely risk estimates.

Response: In judging which of several animal studies to use as the basis for the quantitative risk estimate, the quality of each study is considered as well as the numerical slope factor. As explained in the preamble, an experiment with a small number of animals is rejected in favor of a larger experiment if the two have a similar dose-response relationship. A similar rejection is also made if an experiment is judged to be unreliable for other reasons. Because of the strain, species, and sex differences, it is considered improper to calculate an average response across all animal species and designate this average as the carcinogenic potency for animals in general.

Issue 12

Comment summary: ". . . no experiment, however large and well run, could ever reduce these estimates (criteria)."

Response: In judging which of several animal studies to use as the basis for the quantitative risk estimate, the quality of each study is considered as well as the numerical slope factor. As explained in the preamble, an experiment with a small number of animals is rejected in favor of a larger experiment if the two have a similar dose-response relationship. A similar rejection is also made if an experiment is judged to be unreliable for other reasons. Because of the strain, species, and sex differences it is considered improper to calculate an average response across all animal species and designate this average as the carcinogenicity potency for animals in general.

Issue 13

Comment summary: The EPA method is insensitive to reproducibility of the results, results at lower doses, and the number of animals per dose group.

Response: In judging which of several animal studies to use as the basis for the quantitative risk estimate, the quality of each study is considered as well as the numerical slope factor. As explained in the preamble, an experiment with a small number of animals is rejected in favor of a larger experiment if the two have a similar dose-response relationship. A similar rejection is also made if an experiment is judged to be unreliable for other reasons. Because of the strain, species, and sex differences, it is considered improper to calculate an average response across all animal species and designate this average as the carcinogenic potency for animals in general.

Issue 14

Comment summary: Several examples are given of the failure of the one-hit model to predict cancer rates in humans based on epidemiologic studies:

Analyses of data on: chloroform, carbon tetrachloride, tetracholoroethylene, aflatoxin, chlordane, arsenic, and beryllium.

In a summary of analyses of DDT, dieldrin, and aflatoxin, it is indicated that the one-hit model predicts an incidence of 153,000 liver cancers per year but that the observed response rate from all chemicals in only 3,000 to 4,000 per year. A similar analysis is made of pollution exposure-cancer rates in the Sacramento River area.

Response: For chloroform, carbon, tetrachloride, and tetrachloroethylene the analysis assumed that all of the workers were exposed at the TLV levels for their entire lifetime. In reality most workers are not exposed continuously to levels as high as the TLV and most work for only a few years at these jobs. This procedure overestimates the average lifetime exposure by at least a factor of 10 and the risk estimates for the workers are too high because of exposure assumptions used by the commentor rather than solely because of an overestimated slope factor.

For aflatoxin the commentor showed that the multistage model fits the observed human data more closely than the one-hit model. Therefore, that analysis partially justifies the revised procedure, although this compound is not on the water quality list.

The criterion for arsenic was based on human data, which was linear with dose. However, none of the negative epidemiology studies in areas with high drinking water levels of arsenic was inconsistent with the model developed on the basis of the Taiwan skin cancer data.

Commentors estimated that the annual number of cancer cases caused by beryllium intake is about 14,000. They gave no reason why this number is considered excessive considering that 400,000 cases per year are observed from all causes.

Issue 15

Comment summary: Based on the above types of analyses, several comments recommended that epidemiologic data be used to test and/or modify risk estimates.

Response: The Agency agrees that good epidemiological data should be used to estimate or modify risk estimates. The Agency always preferred using epidemiological data to the animal data in deriving water quality criteria.

Issue 16

Comment summary: Some comments suggest that selection of a particular model should be left open and subject to the nature of the experimental data and epidemiologic or metabolic information.

Response: The Agency does not agree that the selection of a particular model should be left open and subject to the nature of the experimental data for the following reasons. When behavior of the dose-response curve at low doses is not sufficiently understood, it is more appropriate to predetermine the low-dose extrapolation model. Considering the fact that all the mathematically analytic functions such as most of the parametric dose-response curves could be approximated by polynomials which are dominated by the higher order terms in the high-dose range, whereas they are vanishingly small in the low-dose regions it is not surprising to see that different dose-response models could fit well a set of high dose data while their low-dose extrapolations differ drastically. Therefore, the selection of the extrapolation model should be based on knowledge of carcinogenic mechanisms (even though limited and debatable) rather than being determined solely by the high dose behavior of the dose-response curve.

Issue 17

Comment summary: Other comments suggested that the one-hit model should be used only in the absence of data suggesting that other models give a better fit.

Response: See response to Issue 16 and the appendix.

Issue 18

Comment summary: Two comments recommend that several models used for analysis along with appropriate confidence intervals would more objectively reflect the state of scientific knowledge.

Response: The inclusion of several arbitrary models in order to get a range of risk estimates would add no additional scientific information while at the same time would create confusion and thereby undermine the utility of risk estimates. The model chosen by the Agency is regarded as giving a plausible upper limit to the risk.

Issue 19

Comment summary: A general discussion of alternative models is given in some of the comments. Specific models recommended include: Logistic; Probit; Multi-hit; Mantel and Bryan; Weibull; and Pharmacokinetic.

Response: The inclusion of several arbitery models in order to get a range of risk estimates would add no additional scientific information while at the same time would create confusion and thereby undermine the utility of risk estimates. The model chosen by the Agency is regarded as giving a plausible upper limit to the risk.

B. Use of Confidence Intervals

Issue 20

Comment summary: Confidence intervals or a range should be used in deriving criteria.

Response: The Agency feels that the statistical confidence intervals should not be used to express the range of uncertainty of the criteria because this range does not include major uncertainties which are not quantifiable, such as species differences in metabolism, diet, target organ specificity, and other biological variables.

C. Species Conversion Factor $(W_H - W_A)$⅓

Issue 21

Comment summary: Comments suggested that this factor may not be appropriate for carcinogens because: (a) DNA repair rates appear to be inversely proportional to body weight, and (b) mixed-function oxidase activity, which may activate carcinogens, is higher in rodents than in man. Examples were given indicating that man is less sensitive than experimental mammals to chloroform, aflatoxin, and vinyl chloride.

Response: Although some commentors discussed reasons why the species conversion factor, (70/W)⅓, may not be appropriate for particular compounds, no suggestion was made for an alternative method which would be valid in general. Commentors suggested that mixed-function oxidase activity is lower in humans than in rodents and that humans metabolize chloroform less completely than animals, but facts like these, even if quantified would have uncertain implications to carcinogenic potency in general because increased metabolic activity could both enhance carcinogenic potency by "inactivating" the agent.

The fraction of a compound (e.g. chloroform) unmetabolized may have no relation at all to the amount of active metablite formed. In the general method, the cube root factor is intended to account only for the body size difference between animal species as it relates to the availability of the chemical to the body tissues. Any specific knowledge available on metabolism differences would have to be incorporated as an additional factor if it could be directly related to cancer incidence. In general, mixed-function oxidase activity has no clear relation to cancer occurrence, therefore, cannot be included in the general approach.

The best apporach for checking the validity of the species conversion factor is to correlate carcinogenic potency of agents in animals with that in humans where suitable information is available. This was done in a preliminary fashion by Messelson (quoted by one commentor) and is currently being investigated by the Agency.

Issue 22

Comment summary: Data on comparative metabolism should be used, whenever possible, to modify the risk estimate.

Response: See Issue 21 for response to chloroform metabolism issue. The Agency acknowledges that species differences in metabolism should be considered in all cases where the data can be interpreted as being relevant to carcinogenicity. In the methodology description the appropriate place to incorporate this information is in the factor r, called the absorption fraction.

D. Time-To-Tumor Data

Issue 23

Comment summary: Some comments stated that the EPA's modification of the one-hit model does not consider the time-to-tumor concept.

Response: The time-to-tumor concept was incorporated in the one-hit procedure by using the model $P = 1 - \exp(-bd\,t^3)$ where t is the average fraction of a lifetime the tumor was observed and is also incorported into the current approach. If sufficiently well defined time-to-tumor data are available, a more refined model would be used.

Issue 24

Comment summary: Other comments contended that, because of the relationship between dose and latency, even potential carcinogens will not induce tumors in a normal lifespan. Examples were given for beryllium and arsenic.

Response: The arguments given in this comment do not invalidate the criteria which are associated with a lifetime risk of 10^{-6}. The arguments given in the comment proceed as follows:

Let F(d,t) be the probability of cancer by age t at exposure d. F is a monotonic increasing function of both variables t and d. Let d_e be the exposure associated with the lifetime risk of cancer 10^{-6} obtained by solving for d from the equation $F(d,t) = 10^{-6}$ and $t = 70$ which is taken as the average lifespan. Based on the arsenic risk assessment by the CAG the comment argues that at exposure $d_e = 0.002$ µg/liter (where d_e is associated with a lifetime risk of 10^{-6}), the median age would be 2,636 years before cancer can occur, where 2,636 is obtained by solving for t from the equation $F(d_e,t) = 0.5$.

Therefore, if the water concentration is 0.002 µg/l the risk at 70 years is 10^{-6} and at 2,636 years it would be 0.5. These are not inconsistent statements, as implied by the commentor.

Issue 25

Comment summary: One comment suggested that studies in which t is less than 0.75 may not be useful because of insufficient time for tumor development.

Response: The t^3 factor is necessary when the carcinogenic response is so strong that the animals die prematurely of tumors. This is true regardless of whether the median time of death from tumors is greater or less than three-fourths of their natural lifespan.

Issue 26

Comment summary: Another comment raised questions about the experimental difficulties of Druckery's work in precisely determining time-to-tumor development and the need to correct time-to-tumor data for the degree of malignacy of the tumor.

Response: The time-to-tumor data is used only when there was an early terminal sacrifice. In this case the full spectrum of tumor development is observable histologically and the difficulty of observing the precise time of tumor development is not encountered.

E. Mutagenicity Data

Issue 27

Comment summary: Mutagenicity data should be given greater weight to determine potential carcinogenicity especially when mammalian bioassays or epidemiology data are lacking.

Response: See response to Issue 28.

Issue 28

Comment summary: The commentor describes a method for using results from short-term tests, such as the Ames test or the hamster embryo *in vitro* transformation test, to perform quantitative carcinogenicity risk assessment.

Response: The Agency does not regard results from short term mutagenicity tests, even those from a test battery using several organisms, equivalent to chronic whole animal bioassays for carcinogenicity because of the inherent differences between the test systems utilized (i.e., bacteria and cell cultures versus whole animals, in which all the metabolic, distribution and excretion systems of the body are intact). Until correlations between the carcinogenicity and mutagenicity of agents become better understood and more widely accepted, and until the data base is more extensive, the Agency is not justified in making quantitative assessments of carcinogenicity based solely on mutagenicity test results and structure activity relationships. In decisions regarding the carcinogenicity of agents, the Agency currently uses short term bioassay tests only to support equivocal findings of long term animal bioassays and human studies.

F. Epidemiology Data

Issue 29

Comment summary: Epidemiology data on societies other than the U.S.A. should not be used because of "dissimilar and possibly controlling variables."

Response: The CAG feels that epidemiological data on societies other than the U.S.A. population can be used as long as care is taken in interpreting and using the data.

Issue 30

Comment summary: Citing criteria for arsenic and cadmium, the comment states that: "Valid epidemiological studies exploring a cause-and-effect relationship between exposure to a substance and disease must avoid a number of flaws: bias, confounding factors, and the confusion of chance associations with casual relationships. The epidemiological studies used by the Agency in criterion formulation fail to avoid these flaws."

Response: While nearly every epidemiologic study contains flaws in the scientific sense, a regulatory agency must interpret all data available, making judgments as to whether the studies were too flawed for proper conclusions. In determining the carcinogenicity of a substance, the Agency is sensitive to the need to find human populations who have been exposed to other agents also. The appearance of rare types of cancers and/or a dose-response trend, however, often provide(s) very positive evidence of carcinogenicity. Such is the case with the Taiwan drinking water survey. Here, where artesian well water with a high concentration of arsenic has been used for more than 60 years, a high correlation between amount of arsenic and skin cancer was found. In addition, the pre-cancerous skin conditions were pathonomic of arsenic exposure, so that there was little chance that the cancers were caused by another agent. Furthermore, the skin cancer is of a rare form that was virtually unknown in parts of Taiwan where the drinking water arsenic content was small. In addition, a positive association between arsenic level in drinking water and the prevalence of skin cancer has been reported in at least three other areas in the world.

Cadmium is an unusual situation in that five independent populations showed an excess of prostate cancer. Even though each study is inconclusive by itself for the reasons cited, a chance occurrence of this finding is exceedingly unlikely.

While the effect of many possible confounding factors, especially concomitant exposure to unknown chemicals, cannot be accurately determined, the Agency has the responsibility of estimating criteria levels with the best information available.

G. Qualitative Determination of Carcinogenicity

Issue 31

Comment summary: The commentor states that: "A substance is currently considered to be carcinogenic if it produces a statistically significantly higher than normal incidence of tumors in treated animals in a single test. Such a result is inconclusive, because of the problems of false positives.

Response: In establishing a false negative rate of $P<0.05$ the commentors correctly point out that the false positive rate is rather high. However, the careful review of other information about the compound reduces the effective false positive rate.

Issue 32

Comment summary: The decision to label a compound "a suspect human carcinogen and therefore a potential human carcinogen" based on tumorigenicity in experimental mammals has not been validated.

Several comments from the initial publication of the methodology made a similer criticism.

Response: Among public health authorities it is widely accepted that the positive results in chronic animal bioassays indicate that the agent poses a potential risk for human carcinogenicity. This attitude is thoroughly summarized in the IRLG report (Jour. Natl. Cancer Inst. 63: 241, 1979). In addition, a review by Tomatis (Am. Rev. Pharmacol. Toxicol. 79: 511, 1979) emphasized the value of rodent bioassays in predicting human carcinogenic risk.

Since 1976, (41 FR 21402) the EPA has been following the same regulatory philosophy in evaluating carcinogenic hazards. Therefore, contrary to the comments, the EPA has not been acting unilaterally without adequate public notice.

Issue 33

Comment summary: The commentor quotes a WHO publication: "It would be unwise to classify a substance as a carcinogen solely on the basis of a species or strain-specific increased incidence of tumors of a kind that occur spontaneously with high frequency."

Response: The CAG agrees partially with the comment. However, even if the spontaneous incidence is high, a statistically significant enhancement of the tumor incidence is of concern, and other evidence for the compound should be evaluated for consistency with that finding.

Issue 34

Comment summary: Citing PAH as an example, commentors state that the documents have been inconsistent in qualitative determinations of carcinogenicity.

Response: In cases such as PAH where one criterion has to be set for an entire class of compounds, the Agency does not state that each chemical in the class is a carcinogen, as implied by the commentor. Therefore, the PAH example cited by the commentor does not show that the Agency is inconsistent in classifying compounds as carcinogenic.

The intended interpretation of the criterion is that the risk is less than 10^{-5} whenever the total concentration of all PAH compounds in water is less than the criterion. In a hypothetical case where all of the PAH compounds in a sample are non-carcinogenic, the criterion would be too strict; however, this situation seldom occurs. In most cases where PAH is detected, a mixture of compounds occurs and in calculating the criterion the assumption is made that all components have the same carcinogenic potency as benzo-α-pyrene.

Issue 35

Comment summary: Bis(2-chloroisopropyl)ether (BCIE) yielded negative results in an NCI bioassay. Nonetheless, the cancer based criteria based on an upper limit of the true response rate was calculated because of the structural similarity of BCIE to other carcinogenic chloroalkyl ethers. The commentor states that this is inappropriate.

Response: As a response to the public comments, the Agency has changed its interpretation of data on bis(2-chloroisopropyl)ether (BCIE). It is no longer considered to be carcinogenic and, therefore, a criterion based on carcinogenic data is not calculated.

Issue 36

Comment summary: Using the criteria for chromium and asbestos as examples, the commentors state that data on inhalation carcinogenicity should not be used to derive criteria if oral carcinogenicity tests are negative.

Response: The criteria for chromium (Cr) was derived on a marginally significant digestive cancer incidence which occurred from inhalation exposure (Enterline epidemiology study). The digestive system cancer is assumed to be caused by chromium (Cr) which is removed from the respiratory system by mucociliary action and then swallowed. This is comparable to exposure to chromium in drinking water. Cr (VI) has not been adequately tested for its carcinogenic potential in animals; therefore, further studies to assess the carcinogenicity of Cr (VI) by the oral route would be desirable and necessary before it is concluded that oral tests are negative.

Asbestos has been shown to cause peritoneal mesothelioma in humans and is also associated with a significant increase in human gastrointestinal cancers. These are caused by inhaled asbestos. Since up to 99 percent of the inhaled asbestos is eventually swallowed, the Agency feels that asbestos-contaminated water could cause the same type of gastrointestinal cancers as inhaled asbestos.

H. Joint Action/Cocarcinogenicity

Issue 37

Comment summary: The commentors emphasized the potential importance of cocarcinogenicity and possible synergistic effects among carcinogens.

Response: The potential importance of cocarcinogenicity and possible synergistic effects among carcinogens has not been addressed by the CAG in deriving water quality criteria, since sufficient data is not available at this time to make decisive judgments related to these issues.

I. Site Specific vs. Total Tumors

Issue 38

Comment summary: No public comments specifically addressed this issue. However, the methodology committee should discuss the appropriateness of using data on total tumors for quantitative risk assessment.

Response: Since chemicals generally exert their carcinogenic effects at specific organ sites, the incidence of tumors at the responding sites is the most relevant information to consider in making either qualitative or quantitative evaluations of hazard. The instances where the tumor incidence at all sites combined is elevated, but no one site or group of sites is significantly increased, are regarded as weak evidence of carcinogenicity.

J. General Issues

Issue 39

Comment summary: Single unverified bioassays should not be used for establishing criteria for dichlorobenzene.

Response: The comment does not refer to carcinogenicity data since no carcinogenic information was available on dichlorobenzene.

Issue 40

Comment summary: Some comments expressed concern with the types of studies used to derive criteria. Another comment implies that only data published in referenced journals should be used. Two commentors recommend that explicit reasons be developed for accepting or rejecting studies.

Response: The evaluations of bioassay studies for carcinogenicity by the CAG is sufficiently detailed to be equivalent to that given in peer reviewed journals.

Issue 41

Comment summary: The EPA "has used animal studies without adequately considering the nature of the toxic agent and its mechanism of action, the conditions of exposure, or the physiological characteristics of the test organism."

Response: The Agency routinely considers all of the available toxicological data cited by the commentor and agrees that these factors are important.

Issue 42

Comment summary: Several comments questioned the appropriateness of using studies from one route of exposure—particularly inhalation—to establish criteria for ingestion.

Response: If a given chemical induced a carcinogenic effect by inhalation at a distant site, it is likely that the compound could also produce a carcinogenic effect by other routes of administration. Therefore, the Agency considers it appropriate to use inhalation data to derive criteria for ingestion, recognizing the difficulty of determining the dose.

Issue 43

Comment summary: Treating all of the proposed criteria as if they were based upon equally valid data is not scientifically sound. EPA must make explicit the nature, extent, and quality of the data utilized to estimate criteria.

Response: The Agency has indicated which criteria should be regarded as marginal based on the nature of the available data.

Issue 44

Comment summary: Criteria based on carcinogenic effects might not be adquate to protect humans from mutagenic, teratogenic, or other toxic effects.

Response: The U.S. EPA Office of Health and Environmental Assessment is currently developing guidelines for estimating the human risk to substances producing mutagenic, teratogenic, and reproductive effects.

Appendix

I. An Improved Procedure for Deriving Water Quality Criteria

As discussed in the methodology document (1981)[*] the Carcinogen Assessment Group (CAG) has adopted a new prodedure which is more systematic than the one-hit procedure used previously by the CAG for calculating the water quality criteria. The model selected for the low dose extrapolation is given by

$P(d) = 1 - \exp[-(q_0 + q_1 d + \ldots + q_k d^k)]$

At low doses, the upper confidence limit for the extra risk

$$A(d) = \frac{P(d) - P(o)}{1 - P(o)}$$

has the form

$$A_u(d) = 1 - \exp(-q_1^* d) \simeq q_1^* d.$$

That is, the risk $A_u(d)$ is always linerarly related to d at low doses. The constant q_1^* corresponding to the 95 percent upper confidence limit for A(d) is taken as the carcinogenic potency for calculating the water quality criteria.

Instead of extrapolating with the one-hit model based on the lowest dose group showing statistically significant response as previously used by the CAG, the new procedure is employed because of the following reasons: (1) the procedure is more systematic; (2) it invokes fewer arbitrary assumptions; (3) the assumption of the low-dose linearity is not essential in the use of the model, and, (4) it incorporates data from all of the dose groups which are consistent with the multistage model. At the same time, it is conceptually consistent with the linear non-threshold concept on which the one-hit procedure was based.

The Agency recognizes that there is no really solid scientific basis for any mathematical extrapolation model which relates carcinogen exposure to cancer risks at the extremely low level of concentration that must be dealt with in evaluating the environmental hazards. For practical reasons such low levels of risk cannot be measured directly either by animal experiments or by epidemiologic studies. We must, therefore, depend on our current understanding of the mechanisms of carcinogenesis for guidance as to which risk model to use. At the present time the dominat view of the carcinogenic process involves the concept that most agents that cause cancer also cause irreversible damage to DNA. This position is reflected by the fact that a very large proportion of agents that cause cancer are also mutagenic.

There is reason to expect the quantal type of biological response that is characteristic of mutagenesis is associated with a linear non-threshold dose-response relationship. Indeed, there is substantial evidence from mutagenesis studies with both ionizing radiation and a wide variety of chemicals that this type of dose-response model is the appropriate one to use. This is particularly true at the lower end of the dose-response curve; at higher doses, there can be an upward curvature probably reflecting non-threshold dose-response relationships. The linear non-threshold model is also consistent with the relatively few epidemiological studies of cancer responses to specific agents that contain enough information to make the evaluation possible (e.g., radiation induced leukemia, breast and thyroid cancer, and skin cancer induced by arsenic in drinking water, and liver cancer, induced by aflatoxin in the diet). There is also some evidence from animal experiments that is consistent with the linear non-threshold model (e.g., liver tumors induced in mice by 2-acetylaminofluorene in the large scale ED_{01} study at the National Center of Toxicological Research and the initiation stage of the two-stage carcinogenesis model in the rat liver and the mouse skin).

Because it has the best, albeit limited, scientific basis of any of the current mathematical extrapolation models, the linear non-threshold model has been adopted as the primary basis for risk extrapolation to low levels of the dose-relationship. The risk estimates made with this model should be regarded as conservative, representing the most plausible upper limit for risk, i.e., the true risk is not likely to be higher than the estimate but it could be smaller.

II. Comparison of the new Procedure with the Old (One-Hit) Procedure

The Agency had previously calculated the slope b based on the one-hit model P = 1-exp-bd, using only the data from the lowest dose group where the incidence rate is statistically significantly different from the control group (see Federal Register, Part V, Thursday, March 15, 1979). The point estimate b was taken as the carcinogenic potency for the compound. Unlike the new procedure, the upper confidence limit was not used because the CAG recognized that the one-hit model is usually conservative at low doses and thus the point estimate b of the slope was considered as an upper limit of the true carcinogenic potency. This ad hoc approach was used because it is simple and easy to understand.

Since b was considered an upper limit in an ad hoc sense, it would be interesting to compare the new procedure with the one-hit procedure by calculating the ratio of two carcinogenic potencies b/q_1^* for 21 chemical compounds in the Proposed Water Quality Criteria Documents which have data from at least three dose groups. Except for chlordane and heptachlor the new procedure agrees with the one-hit procedure within a factor of 2. When the one-hit procedure is modified (Table 1) the two procedures become comparable. Therefore, the old procedure could be used as a simple and quick way of estimating the carcinogenic potency.

Table 1.—*Ratio of Carcinogenic Potencies*

Chemicals	b/q_1^*	
Chlordane	3.33	[1] (0.83)
Heptachlor	2.50	[1] (0.78)
Carbon tetrachloride	1.47	
PAH	1.36	
HCB	1.19	
1,2-Dichloroethane	1.18	
Acrylonitrile	1.10	
Hexachloroethane	1.06	
2,4,6-Trichlorophenol	.96	
Trichloroethylene	.95	
Hexachlorobutadiene	.88	
Chloroform	.81	
1,1,2,2-Tetrachloroethane	.75	
1,1,2-Trichloroethane	.70	
TCDD	.66	
2,4-Dinitrotoluene	.63	
Vinyl chloride	.63	
Toxaphene	.56	
Aldrin	.56	
Bis(chloromethyl)ether	.53	
Hydrazobenzene	.50	

[1] The parenthesized value is the ratio b/q_1^* when b is calculated based on the 95 percent upper confidence limit (one sided) for the incidence rate in the next lowest dose group, instead of using the incidence rate of the lowest dose group showing statistically significantly different from the control group. This modification was recommended when the tumorigenic responses exhibit sharp upward curvature with low doses.

AMERICAN INSURANCE ASSOCIATION:

PRELIMINARY PAPER ON PROPOSED HAZARDOUS SUBSTANCE VICTIM COMPENSATION LEGISLATION

I. INTRODUCTION

The American Insurance Association is a trade association composed of more than 160 publicly owned insurance companies providing property and casualty coverages. The Association's members provide the majority of general commercial liability insurance in the United States. It is likely that the members of the American Insurance Association will be asked to provide insurance for those subject to liability for hazardous substance compensation. A market for such insurance can develop only if the compensation liabilities to be insured are both reasonably predictable and affordable. The members of the American Insurance Association, and other insurers, have responded in the past to the emerging environmental liabilities; new coverages have been developed and competitively marketed. Thus, the American Insurance Association has an interest in seeing that the liability system as it develops is reasonable, equitable and insurable.

This Paper expresses the position of the American Insurance Association in response to state and federal legislative proposals concerning "hazardous substance" liability claims. Many of these bills are based in part on recommendations made by a majority of the

"Superfund Section 301(e) Study Group" (the "Study Group majority") in a Report dated September 1982 (the "Report") entitled Injuries and Damages from Hazardous Wastes -- Analysis and Improvements of Legal Remedies, submitted to the United States Congress pursuant to Section 301(e) of the Comprehensive Environmental Response, Compensation, and Liability Act of 1980 ("CERCLA"), P.L. 96-510.

II. EXECUTIVE SUMMARY

The law of torts, as implemented through our nation's courts, is the primary medium for resolving disputes as to compensation for claimants alleging injury from exposure to hazardous substances. The tort liability system as it has evolved over the centuries -- and as it continues to evolve today -- is designed to serve three functions: justice, compensation, and incentives for proper conduct. Ideally, a plaintiff will receive compensation in the courts only if it is just to require the defendant to pay, and if requiring such payments overall will tend to provide proper incentives for prudent behavior and to minimize the incidence and seriousness of such damage in the future.

Under traditional principles, a defendant whose fault or abnormally dangerous activity is determined to have caused an injury must compensate an injured claimant; such a determination is consistent with our notions of justice and fair play, and also serves as an incentive to that defendant and others, to do better in the future. Moreover, an injured plaintiff may not obtain compensation from parties randomly selected out of the general population who have not caused the injuries at issue and who have not engaged in any improper or abnormally dangerous activity; compensation is not provided in such a case because it would not be consistent with our notion of justice, would not penalize the parties actually at fault or encourage them and others to be more careful in the future.

The Study Group majority, and the sponsors of various bills subsequently introduced, have advocated radical departures from the present common law tort system to ease plaintiffs' burden of obtaining damages for personal injury or property loss allegedly resulting from exposure to certain hazardous substances. These proposals include devices such as:

1. A presumption that hazardous substances caused a plaintiff's injuries or disease where plaintiff cannot show that this is the case.

2. Absolute liability, without any regard to the presence or absence of fault on the part of the defendant.
3. The imposition of liability on a particular defendant far in excess of the harm that defendant caused, through the use of presumptions that a particular defendant's substance caused harm when no proof of that fact is available, and the use of joint and several liability.
4. The use of administrative remedies partially or completely funded by a tax on certain industries, which falls on good and bad actors equally and removes any incentives for proper conduct.
5. The imposition of retroactive liability.
6. The use of an administrative "compensation" scheme as an add-on to potentially unlimited tort liability, thus providing both widespread recoveries under relaxed standards of proof, and no limitation on the amount of recoveries that are available.

The American Insurance Association opposes such radical proposals because they detract from the combined ideals of justice, compensation and incentives for proper conduct that are the basis of the present tort system, and because it has not been demonstrated that such legislation is necessary or will improve the present system.

The proposals made thus far have the potential of providing awards for every case of cancer, tumor, genetic damage, and other diseases of the type claimed to result from "exposure" to hazardous substances. The cost of the proposed legislation would run into tens of billions of dollars per year for American industries -- a cost far in excess of any harm that has been demonstrated to be caused by hazardous substances, as opposed to the many other factors that affect our everyday lives and health.

Enactment of the specific proposals recommended by the Study Group majority and others, in addition to providing costly and unfair presumptions of causation not warranted by scientific or other evidence, would remove all incentives for industry to use due care in handling hazardous substances, since everyone would be penalized (through absolute, joint and several liability and through taxes) without any regard to fault or lack of fault. Thus the goal of preventing future harm would be abandoned in favor of an overbroad system of after-the-fact compensation. Moreover, the use of an add-on system of administrative recovery in addition to a system of unlimited courtroom recovery would constitute perhaps the most expensive and cumbersome compensation system that could possibly be devised.

The American Insurance Association believes that the proposals, which combine staggering costs, unlimited and unpredictable liability, and the abandonment of the traditional requirements of fault and causation, would be uninsurable, unaffordable, unjust and unwise.

III. THE STUDY GROUP MAJORITY'S RECOMMENDATIONS

Because most of the proposed legislation suffers from the same generic problems that are inherent in the Study Group majority's Report, a brief summary of the Report is included here.

The Study Group was comprised of twelve lawyers, three each appointed by the Presidents of the American Bar Association, American Law Institute, American Trial Lawyers Association, and the National Association of (State) Attorneys General. No medical, scientific, epidemiological, economics, industrial or underwriting experts were included in the Study Group.

The Study Group majority recommended that a two-tier recovery system be established. Tier One would provide an administrative remedy administered by the states but governed by federal law. (Report at 206).* Tier Two -- which would also be available even if a claimant first received a Tier One administrative award --

---

* Citations in this form refer to the pagination of Volume One of the Report as printed by the Government Printing Office, Serial No. 97-12. Volume Two contains lettered appendices to the Report.

would consist of the judicial tort-claim process, modified to make recovery of damages (including damages for pain and suffering, and punitive damages) far easier for plaintiffs.* Vehement dissents from these proposals were recorded in the individual comments of certain Study Group members, especially Chief Judge (ret.) Charles D. Breitel and George Clemon Freeman, Jr.**

Tier One

Tier One administrative remedies as recommended by the Study Group majority would permit recovery of full medical costs (without limit) and 2/3 of lost wages (up to a fixed monthly limit). Death benefits would also be paid to family members who had relied on the decedent for support. (Report at 206, 234).

Tier One administrative recoveries would be based in many cases upon a presumption of causation:

> "If the claimant in an administrative compensation proceeding proves:

---

* Through the use of joint and several liability, broader strict liability principles, liberal joinder rules and a more liberal statute of limitations. (Report at 255-60).

** Comments by Charles D. Breitel, Study Group Member (Report at 295); Comments of George Clemon Freeman, Jr. (Report at 305)

> 1) that the source involved in the claim was engaged at the time of exposure in the production, transportation or disposal of hazardous wastes; and
>
> 2) that the claimant was exposed to such hazardous waste by proximity, contact, ingestion, inhalation, or by some other form of exposure; and
>
> 3) that the claimant suffered death or the kind of injury or disease which is known to result from such exposure
>
> then the following rebuttable presumptions should arise:
>
> (a) that the exposure to the hazardous waste generated, transported or disposed of, by or in the source, contributed to the death, injury or disease of the claimant; and
>
> (b) that the source by or in which such hazardous wastes were generated, transported or disposed of was responsible for the claimant's exposure and for the resulting death, injury or disease." (Report at 213-14 (indentation added)).

A claimant would not be required to demonstrate any fault on anyone's part in order to recover. (Report at 196, 209).

The Study Group majority made no study of the expected or potential costs of its proposed program. It did recommend that the fund out of which these administrative recoveries would be paid be provided initially through a tax on industry. (Report at 245). Further funding would be provided by subrogated agency claims against the owner, operator, generator, transporter, or other "alleged responsible party" after the agency had paid a claimant. (Report at 246). Such subrogated claims by the agency would be made on the same basis as a claimant's original claim -- *i.e.*, including the presumption of causation and lack of any required proof of fault; subrogated claims would not require proof that an owner, operator, generator, or transporter, etc., knew or should have known of the hazard. (Report at 246-47). Thus, a defendant's liability would be nearly absolute.

Tier Two

A Tier One administrative award would *not* bar a claimant from pursuing further damages in court under Tier Two. The agency granting a Tier One award would be reimbursed from any court award. The Study Group majority recommended that the courts be empowered to assess costs against a plaintiff who had previously obtained an administrative award, if the plaintiff failed to receive an award in court at least 25% larger than that granted by the agency. Such cost assessment, however, would not be mandatory. (Report at 197-98).

The Study Group majority recommended that the judicial process adopt a very liberal statute of limitations (based not only on discovery of the injury or disease but also on discovery of the cause of the injury or disease), liberal joinder rules, and joint and several liability for each defendant who has "contributed" to the injury, above some de minimis level. (Report at 255-58).

IV. DEFECTS IN THE PROPOSALS

A. Proponents' Failure to Demonstrate a Need for Radical Change

The proposals of the Study Group majority and others have been put forward despite the complete absence of evidence that large groups of plaintiffs exist with injuries caused by hazardous substances who will not be compensated by the present common law tort system. In the absence of any such showing, the American Insurance Association opposes legislation that would so radically alter traditional common law remedies and would render uninsurable those who would be subject to the new liabilities.

The lack of any reliable scientific basis underlying these calls for legislative reform is admitted in the Report:

> "The discussion of legal issues relating to injuries from hazardous wastes must proceed in a setting of factual and scientific uncertainty because, at this time, in mid-1982, it is impossible to determine the number of persons who

> have been injured or who could be injured by exposure to such sites." (Report at 21, footnote omitted).

Study Group Member George C. Freeman, Jr. in a letter dated March 2, 1982 (included in Volume Two of the Report) noted:

> "We have very little reliable information about how much truly toxic wastes are out there and how many persons may or may not have been exposed to them in circumstances that have caused, or are likely to cause, death, serious bodily injury or disease.
>
> * * *
>
> If relatively few people have in fact been injured by (or even exposed to) toxics, the fact that few cases for damages have been successfully brought should not be regarded as evidence that the current law is inadequate or unfair." (Id.)

Premature public outcry is not unprecedented in the field of hazardous substance legislation. In 1980 the Environmental Protection Agency released a study purporting to show chromosome defects among residents near the Love Canal. Based in large part on this study, more than 700 people were evacuated from the area by the federal government; a public outcry was launched and CERCLA was passed later the same year. Subsequent reports, however, reveal that this study "was so poorly designed that it should never have been undertaken."[*] A subsequent study released on May 17, 1983, by the Centers for Disease Control found no increase in chromosomal abnormalities among Love Canal residents (including 17 such residents who had participated in the original study) when compared to a comparable control group.[**] This newest study also noted that other "[e]xtensive studies at the Love Canal dump site in Niagara Falls, New York, giving particular attention to reproductive abnormalities and to cancer, have thus far defined no firm evidence of increased disease incidence or mortality . . . ."[***]

---

[*] Boffey, "Study of Love Canal Finds No Direct Link to Genetic Disease", *New York Times*, May 18, 1983, at A1, col. 6. No comparable control group was used in the original study.

[***] CDC Study at 1. Similarly, there is no evidence that the tort system has failed in the oft-cited Environmental Law Institute study entitled *Six Case Studies of Compensation for Toxic Substances Pollution: Alabama, California, Michigan, Missouri, New Jersey, and Texas* (Senate Comm. on Environ. and
(Footnote continued)

Given this background, legislatures should be cautious and not rush headlong into enacting overbroad "reforms." For example, in September 1981 the State of California established a Hazardous Substance Compensation Account (Cal. Health & Safety Code §§ 25300-95) to provide compensation "for loss caused by a release, in California, of a hazardous substance" if the release was from an unknown source or an unknown liable party, or if the liable party could not be found, or was judgment proof. As of March 1983, not a single direct claim had been asserted against the fund.* Despite publicity concerning the lack of claims made against the fund,** at

---

(Footnote *** continued from previous page) Public Works, 96th Cong., 2d Sess., Serial No. 96-13, Comm. Print, June 1980) (hereinafter "Six Case Studies"). Of the six cases studied -- which six were chosen specifically because they were believed to demonstrate "substantiality of harm" and not on any random basis -- only two included any evidence of serious personal injuries due to chemical exposures, and certain injured persons received compensation in each of those two instances. This two-month study heavily reflected the personal views of the authors, but failed to afford those views an evidentiary support.

* See Hazardous Waste Management Council, Compensation: An Analysis of Hazardous Waste Facility Insurance Requirements and Alternatives 28 (January 1983).

** "California Cleanup Fund Has Money Begging," New York Times, Monday, March 21, 1983, at A12, col.6.

the present time less than a dozen claims have been filed.

In view of these facts, North Carolina has recently adopted a more cautious approach. The 1982 Annual Report and Special Reports of the North Carolina Governor's Waste Management Board, while recommending certain limited changes in the application of strict liability principles under the tort law system, rejected an administrative remedy or any presumption of causation. (Id. at 53-56). With respect to administrative remedies:

> "The Board concluded that it is premature at this time to assume that the volume or complexity of hazardous waste liability cases will be so great that the general court system cannot handle them adequately." (Id. at 56).

B. Proponents' Failure to Consider the Staggering Costs of Their Overinclusive Proposals

It would be disastrous to structure a radical new "solution" in such a way as to eradicate the traditional tort law requirements that a plaintiff show a defendant was at fault and caused the harm complained of.* Such a "solution" would, in effect, require the chemical and oil industries to pay the costs of cancers, tumors, genetic damage, joint pains, headaches and other diseases or symptoms every time a claim of "exposure" to toxic waste was lodged, even if (as would almost always be the case) the claimant's disease resulted from a combination of other causes such as normal environmental or genetic factors unrelated to exposure to toxic waste. (See further discussion of the specific legal principles below).

---

* Moreover, any "solution" that abandons these elementary principles might have serious ramifications for tort law in other areas, which no one intended to "reform."

For example, consider the present cancer statistics - just one disease that might result from exposure to hazardous substances. In 1983, an estimated 440,000 Americans will die of cancer, and an estimated 855,000 people will be diagnosed as having cancer.* Statistics show that more than 20% of the total deaths among Americans resulted from some form of cancer -- the second highest cause of death, after heart disease.** Yet, it has been estimated that approximately 2% (and no more than 5%) of cancer deaths are caused by air, water and food pollution in all its forms;* 1% or less may result specifically from exposure to pollutants found in hazardous waste sites.** However, the Study Group's proposal, echoed in many of the pending legislative proposals, would permit recovery by anyone who can claim non-occupational "exposure" to hazardous waste dumps and whose ailment cannot be demonstrated not to have resulted from such exposure -- an impossible burden for a defendant to meet, as more fully discussed below. Such a skewed system would certainly involve many times the number of recoveries than would be warranted by the small percentage of diseases arguably "caused" by hazardous substances.

---

* E. Silverberg & J. Lubera, Cancer Statistics, 1983 10 (reprinted from Ca-A Journal for Clinicians, Vol. 33, No. 1, 1983 (American Cancer Society).

** Figures for 1978 (the last available year). Cancer Statistics, 1983, supra, at 11.

In light of these facts, the cost of the Study Group majority's overinclusive "solution" would be staggering. Just as with other types of compensation programs begun in the 1960s and early 1970s the costs can be expected to balloon to truly massive proportions. See "Toxic-Liability Bills Plant a Time Bomb of Entitlement Costs," The Wall Street Journal, Friday, June 3, 1983, p. 20, col. 3; Office of Management and Budget, Compensation for Toxic Substances Exposure (May 19, 1983). The experience under the federal Black Lung Benefits Act provides an apt warning:

---

* See R. Doll & R. Peto, The Causes of Cancer: Quantitative Estimates of Avoidable Risks of Cancer in the United States Today, 66 J. Nat'l Cancer Inst. 1192, 1245-50. 1256 (1981); Technology Assessment Board, 97th Cong., Assessment of Technologies for Determining Cancer Risks from the Environment 91 (June 1981).

** Comments of Jim J. Tozzi at a conference on May 7, 1983 concerning Office of Management and Budget-sponsored Inter-Agency Study of Toxic Torts.

> "The Black Lung Act provides an example of what can happen when a compensation system is not well thought out. A General Accounting Office report issued in January 1982 found that 84 percent of claims were paid without adequate medical evidence.
>
> The result: In 1969, Congress estimated that the total program would cost between $40 million and $385 million. By 1972, costs to the federal government alone amounted to $33 million per month. In 1979, such costs amounted to $1.5 billion and reached $2 billion in 1982. The total cost of the program, including benefits paid directly by industry, is unknown."*

As a result, in 1981 Congress eliminated many of the presumptions of causation in the Black Lung Act because they had "led to an excessive number of claims and vastly greater expenditures than had been anticipated." (Report at 228). Black Lung Act costs are expected to level off or slightly decrease over the next few years.* Nonetheless, one critical presumption remains -- a rebuttable presumption that certain identified diseases were work-related if the employee could show 10 years of employment. Consequently, costs will not decline very quickly, and in fact continued to rise in 1982.**

---

* J.B. Browning (Chemical Manufacturers Association), Public Compensation: A Chemical Industry Perspective 9 (April 5, 1983); see Problems Relating to the Insolvency of the Black Lung Disability Trust Fund: Hearings Before the Subcomm. on Oversight of the Comm. on Ways and Means of the House of Representatives, 97th Cong., 1st Sess. 2-15, 159-88 (1981).

The Black Lung Act is very limited in scope; costs for a sweeping hazardous substance program would be enormous, given the broad presumptions, unlimited awards and huge administrative costs inherent in the pending proposals.

To obtain a rough concept of this cost, assume that the number of cases that would be filed for all the types of diseases which plaintiffs may claim could result from exposure to hazardous substances -- cancer, respiratory ailments, tumors, genetic defects, coronary disease, etc. -- might be so low as one-fourth of the diagnosed annual number of cases of cancer alone. Rounding downwards, such an assumption yields an incidence of approximately 200,000 claims filed per year.*

---

* Office of Management and Budget, Compensation for Toxic Substances Exposure, Chart 2 (May 19, 1983).

** Id. Further, the use of a presumption that a disease is work-related in the context of the Black Lung Act or workers' compensation statutes is inherently a limited one; the list of employees on the roster is finite and easily ascertainable. Such a presumption relating to hazardous substance exposure is open-ended, uncontrollable and potentially limitless in scope.

At this conservatively estimated rate of claims, and given the same average recovery in Tier One that is estimated for current workers' compensation cancer cases of $130,000 per award,** the Study Group's program would result in an annual cost of $26 billion in Tier One claims payments alone.*** Assuming allocated loss adjustment expenses (i.e., defense legal fees, etc.) of approximately 10% added to the total cost of these cases,* the annual bill in Tier One alone might be on the order of approximately $28 billion.

---

* In view of the claims of the Environmental Protection Agency ("EPA") and legislative proponents, this number of cases is entirely within the bounds of possibility. EPA has claimed there are over 80,000 sites in the nation with contaminated surface impoundments, 90% of which "are believed to pose at least a potential threat of ground water contamination." Technology Assessment Board, 98th Cong., Technologies and Management Strategies for Hazardous Waste Control 5 (March 1983). Under the Study Group majority's approach, residents around these sites showing "exposure" may be able to recover, even where such "exposure" did not actually cause their disease or injury.

** Source: National Council on Compensation Insurance. See Technical Appendix A.

*** I.e., 200,000 claims times $130,000 per award. To put this annual cost in perspective, it represents more than twice the total workers' compensation loss and loss expense incurred by private carriers and state funds in 1981 (almost $12 billion), and would

(Footnote continued)

Additional awards to plaintiffs in Tier Two would add massive costs such as pain and suffering awards, attorneys' fees and litigation expenses. To the extent this estimate is conservative in its assumptions, it follows that the actual cost of the program will run even higher.

To require that this extraordinary cost -- far in excess of any proven level of injuries caused -- be shouldered by a few American industries would seem very

---

(Footnote *** continued from previous page) add 7.0% to the inflation rate of chemical and petroleum product prices (given 1982 sales of $371 billion), along with a similar effect on the prices of all other goods and services that incorporate these products, if an industry tax were passed through to consumers.

* The National Council on Compensation Insurance figures showed allocated loss adjustment expenses of 10%, but it is reasonable to expect that for cases proceeding on through Tier Two litigation, such expenses would be three to four times higher. The Study Group majority's proposal provides no abatement in these transaction costs, since plenary court lawsuits are not barred; indeed, the Study Group's proposal merely adds the administrative costs to the present system.

unwise, especially in the face of foreign competition which would not be burdened by similar costs. See Letter dated March 10, 1982 by Study Group Member George C. Freeman, Jr. (included in Volume 2 of the Report). In addition, as the cost of complying with the law rises, the incentive to engage in illicit, secret dumping or to employ other illegal means of waste disposal rises.* Further, to assume that such an extraordinarily costly scheme is insurable, or worse yet to dismiss the issue with the Study Group majority's assertion that:

---

* Concern has already been expressed that organized crime may be involved in the garbage and waste disposal industry. See, e.g., "Corruption Cited in Waste Business," New York Times, Sunday, May 1, 1983, at A52, col. 4; "Attorney Denies Dumping, Mob Connection," UPI Regional News story, Friday, April 29, 1983; "Poison Dump Stirs Alarm in Poconos," New York Times, Sunday, April 24, 1983, at A20, col. 1. As the New York Times reported last year in connection with the conviction of Russell W. Mahler:

> "New York can handle only 60 percent of the 1.4 million tons of industrial waste that companies in the state produce annually, and the pressure to get rid of some of it by illegal means is tremendous, according to state officials. 'If you pay the price, you can dispose of hazardous waste, but the price can be prohibitive,' said Jeremiah B. McKenna, counsel to the State Senate's Select Committee on Crime."

Chavez, "Toxic Waste Entrepreneur," New York Times, Thursday, May 27, 1982, at D1, col. 1.

> "insurability is not the sole or even the dominant factor that ought to determine whom the law protects and how,"*

is to court disaster. If no insurance were written to cover these risks, or if industry is unable to afford the premiums, there would be no effective means of spreading the enormous cost of the proposed system while at the same time offering the incentives to careful conduct that are traditionally provided by variable commercial insurance rates. Without insurance, it is unclear that our vital industries would even be able to meet this level of risk without jeopardizing their very existence. Unfortunately, this is precisely the perilous course which the Study Group majority, and proposed state and federal legislation modelled on its recommendations, would have us adopt.

---

* Report at 185. See Letter dated May 17, 1982 from George C. Freeman, Jr. (included in Volume Two of the Report), which questioned the availability of insurance to cover the Study Group's proposals.

C. Proponents' Failure to Consider the Ramifications of the Specifics of Their Proposals

1. The Presumption of Causation

The heart of both the Study Group's Report and many of the legislative proposals introduced is a presumption that diseases contracted by an "exposed" person were caused by that exposure. But in fact, such diseases have a multiplicity of possible causes, of which hazardous substance exposure may be one of the least significant when compared with diet and certain habits (such as smoking).* The Study Group majority's attempt to legislate science, without regard to the actual facts that are available, is echoed in the vast majority of the bills that have been submitted to state and federal legislatures.**

** See, e.g., Massachusetts H. 5179, § 7(a); S.917, § 5(c)(3); S.946, § 3(b); H.R. 2330, § 102(a); cf. Minn. Stat. § 115B.07. Indeed, Senator Mitchell's proposal in S.946, after providing a "rebuttable presumption", goes on to state:

> "Evidence as to the physical weakness or personal habits of the individual on whom

(Footnote continued)

It may be impossible for a defendant to prove lack of causation from an exposure, given the long latency period for many toxic waste related diseases. Plaintiff, and not defendant, is in possession of all the facts concerning the onset of disease and the symptoms involved, personal diet and habits that might be the cause of the disease, and all background information concerning plaintiff's history and exposure to this or other hazardous substances. None of this information is public, unlike much of the information about hazardous substances in dump sites collected by the federal government under CERCLA. See, e.g., 42 U.S.C. § 9603(c).

Given ordinary human sympathies, a burden to disprove causation would be much harder for a defendant to sustain than it would be for a claimant to prove causation affirmatively. Thus, industry members would become virtual guarantors for the costs of all diseases and

---

(Footnote ** continued from previous page)

> the claim is based shall not be used to rebut the presumption created by this paragraph."

Thus, for example, a person who contracted lung cancer after an exposure to hazardous substances would presumably recover under this formulation on the basis of the exposure, no matter how heavy a smoker he is. Smoking, however, might be many times the more significant contributory factor.

genetic defects occurring in an indeterminate population that lives, works, and vacations in, and perhaps even passes through, the vicinity of every hazardous waste site, without any real regard for whether the harms claimed were actually caused by the hazardous substances, or whether they resulted from or were primarily contributed to by other causes.

Insurance industry representatives and members of the Study Group itself also expressed concern that, despite a lack of any recommendation so providing, the presumption of causation available to claimants in a Tier One administrative proceeding would likely be imported into Tier Two by the courts,* resulting in full recoveries (including pain and suffering damages) to a large number of plaintiffs without proof of causation. This concern is heightened by examples such as the Minnesota Environmental Response and Liability Act (the "Minnesota Act"), passed in May 1983, which provides in Minn. Stat. § 115B.07 for restrictions on directed verdicts -- a provision that amounts in practice to a presumption.* This *de facto* presumption is by its terms made applicable to actions brought under the Minnesota Act "*or any other law* to recover damages for death, personal injury, or disease arising out of the release of a hazardous substance . . . ." *Id*. (emphasis added).

---

* Report at 175, 264-65; Comments of Study Group Member Charles D. Breitel (Report at 300); Comments of Study Group Member George Clemon Freeman, Jr. (Report at 318).

2. Liability Without Regard to the Defendant's Fault or Lack of Fault

The Study Group majority recommended that all consideration of fault be eliminated entirely in both Tier One and Tier Two proceedings.** Even the attenuated fault concepts embodied in the "strict liability" provisions of the Restatement (Second) of Torts § 519-52 would be disregarded by the Study Group majority.

---

* Minn. Stat. § 115B.07 prohibits a directed verdict for the defendant on the issue of causation if plaintiff "produces evidence sufficient to enable a reasonable person to find that" (a) the defendant is responsible for the release of the hazardous substance; (b) the plaintiff was exposed; (c) "the release could reasonably have resulted" in the amount and duration of plaintiff's exposure; and (d) "the death, injury, or disease suffered by the plaintiff is caused *or significantly contributed to* by exposure to the hazardous substance in an amount and duration experienced by the plaintiff." The statute continues:

> "*Evidence to a reasonable medical certainty that exposure to the hazardous substance caused or significantly contributed to the death, injury or disease is not required* for the question of causation to be submitted to the trier of fact." *Id*. (Emphasis added).

** Report at 196, 209, 260, 265-66.

The Second Restatement applies a strict liability standard to abnormally dangerous activities. At the same time, it:

> "cautions against defining a type of activity as 'abnormally dangerous' in and of itself, however, and advocates considering the activity in light of surrounding circumstances on the facts of each case. This, in essence, shifts consideration from the nature of the activity to the nature and extent of the risk."

Clark-Aiken Co. v. Cromwell-Wright Co., 323 N.E.2d 876, 887 (Mass. 1975) (stated with respect to the Tentative Draft of the Second Restatement). Section 520 of the Second Restatement provides:

> "In determining whether an activity is abnormally dangerous [and thus gives rise to strict liability], the following factors are to be considered:
>
> (a) Whether the activity involves a high degree of risk of some harm to the person, land or chattels of others;
>
> (b) Whether the gravity of the harm which may result from it is likely to be great;
>
> (c) Whether the risk cannot be eliminated by the exercise of reasonable care;
>
> (d) Whether the activity is not a matter of common usage;

> (e) Whether the activity is inappropriate to the place where it is carried on; and
>
> (f) The value of the activity to the community."*

Thus, the Second Restatement requires a court to consider whether an activity is necessary to society and is being carried on in an appropriate location, among other things, before finding it to be "abnormally dangerous" and imposing "strict liability" for injuries that result from such an activity.

The Study Group majority, however, would impose strict liability without first considering all the circumstances. The Study Group majority stated:

> "Formulations of strict liability that balance the hazard of the activity against its utility and its appropriateness to the locale import considerations of negligence that entail significant barriers to the recovery of damages for injuries from exposure to hazardous wastes. To remove these barriers, the application of a theory of strict liability is needed that focuses on the nature of the hazardous waste activity itself, and on the magnitude of the risk." (Report at 260).

The trend in tort law today is not toward absolute liability such as was recommended by the Study Group majority, but rather toward more limited "strict liability" concepts based on the Second Restatement.* Today the overwhelming majority of states that have considered Section 520 of the Second Restatement have utilized its factors in determining cases.**

---

* Under the case law, disposal of hazardous waste has not uniformly been found to be abnormally or inherently dangerous. See Ewell v. Petro Processors of Louisiana, 364 So.2d 604 (La. Ct. App. 1978).

This acceptance of the Second Restatement's factors is based upon sound considerations. These same factors are, in part, the criteria used by underwriters to determine insurance premium rates for a particular insured. Absolute liability, without any regard to proper conduct, on the other hand, leaves no room for consideration of fault, and provides no incentive for companies to behave well in handling their hazardous substances. An absolute liability system would penalize necessary industries conducted in a reasonable manner just as heavily as marginally useful, irresponsibly conducted activities; careful conduct would become irrelevant. The balanced approach of the Second Restatement should not now be abandoned in favor of an ill-considered stampede to an absolute liability standard.

Port of Seattle, 80 Wash. 2d 59, 491 P.2d 1037 (1971); Peneschi v. National Steel Corp., 295 S.E.2d 1 (W.Va. 1982). But see New Jersey v. Ventron Corp., 182 N.J. Super. 210, 440 A.2d 455 (App. Div. 1981).

3. Imposition of Excessive Liability on Non-Responsible Defendants

The use of absolute liability without regard to fault is particularly far-reaching in light of the Study Group majority's recommendation that defendants be jointly and severally liable in a court proceeding. (Report at 257-58). Thus, a very prudent manufacturer who merely had the misfortune to place his waste in the same site as another, who acted intentionally or even criminally, could be held liable for the entire judgment. If the negligent enterprise cannot be found, or is judgment proof, the prudent manufacturer will be forced to bear the entire liability without recourse despite careful and proper behavior.

This situation is exacerbated further by the presumption proposed by the Study Group majority. Under that presumption, for example, a claimant might simply prove his exposure to "Substance X" and that a particular manufacturer deposited "Substance X" in the dump site the claimant asserts is the source of the contamination affecting him. In a subrogated liability proceeding against the manufacturer, liability would be found unless the manufacturer meets a burden of showing that somebody else's "Substance X" was the source of the contamination. If there was a lack of historical evidence, as may often be the case, such a burden could not be maintained. Thus, a perfectly prudent, careful and non-responsible party who dealt in "Substance X" might ultimately bear a liability for harm it never caused, but which was instead caused by the irresponsible activities of another person. The unpredictability of this liability, coupled with its potentially huge amount, would make it extremely difficult to insure.

4. The Initial Funding Tax and Further Removal of Incentives for Careful Handling of Hazardous Substances

The proposal that a compensation program should be initially funded through taxes on industry* would place an impossibly high burden on domestic industries already faced with stiff foreign competition unburdened by such expenses. See Comments of Study Group Member George Clemon Freeman, Jr. (Report at 311-14). Funding by such a generic tax burden prevents an enterprise from reducing its cost by prudent behavior.

> "The Study Group claimed that the costs of injuries should be carried by the industry or enterprise that creates them 'because efforts to reduce the cost will result in greater care, more safety and protection of the public' . . . [see Report at 248]. Though this generalization is often true, it is an inappropriate justification of the proposed tax.
>
> The Study Group's rationale is wrong on at least two counts. First, a tax on industry output provides little or no incentive for any single enterprise to reduce its liability. A firm does not reduce its tax burden by taking due care to avoid hazardous waste damages; therefore, such a funding mechanism simply does not act as a deterrent. Secondly, the fund is only applied to exposures that have either happened in the past or for which there is no responsible party; obviously, it is impossible to deter this type of exposure and, consequently, the tax provides no appropriate incentives. . . ."**

---

* Report at 245.

(Footnote(s) ** will appear on following pages)

Such a tax would eliminate the use of commercial insurance, thus further removing any incentive to handle hazardous substances properly, and eliminating a valuable social mechanism of industrial self-regulation.

Insurance is a method of assessing and spreading risk, which has proven to be efficient in determining proportionate potential liability. Each insurer, in competition with all other insurers, puts itself at risk based upon its determination of an insured's potential liability. Using underwriting criteria that include not only statistical data but also loss control and loss prevention expertise, an insurer makes a determination as to which facilities or activities it will insure. In so doing, insureds that may treat or deal with the same quantity and type of toxic substances may be charged different premiums for their coverages because of judgments made by underwriters that reflect tangible and intangible qualities ranging from record keeping, to attitude toward loss control, to the level of personnel dealing with loss control and prevention.

** National Economic Research Associates, Inc., The Role of Economics in Tort Law Reform, (Draft Memorandum by F. Dunbar), at 10-11 (November 8, 1982).

Myriad factors, together with the personal experience of the underwriters, will determine the effectiveness of the underwriting process. This process is totally unlike a tax system, which treats the facilities disposing of the same or similar quantity or type of toxic substance in an identical manner, as though they were identical. The insurance mechanism, operating in conjunction with a sound tort system, provides carefully honed financial incentives to proper behavior and injury prevention, which can never be duplicated by a tax-based system.

5. Retroactivity

> "[I]f regulation under RCRA is effective, there is hope that there will be few cases of injury from hazardous waste in years to come. The recommendation for the compensation remedy is based on the possibility and concern that past hazardous waste disposal practices may have created a backlog of injuries and exposures that the legal system will need to clean up." (Report at 195).

With these words, the Study Group majority focused its attention on the issue of retroactive liability, relying heavily upon the speculative "possibility" that past practices "may have created" an as yet unidentifiable "backlog" of cases for the legal system to "clean up."

The pitfalls for the insurance industry of creating new, massive, retroactive liability for past practices are well known. The imposition on insurers of new obligations beyond those contemplated by the parties to the insurance contracts could be devastating to the entire insurance industry. Insurers have collected their premiums and set aside reserves based upon the law as the parties understood it at the time of contract. It is neither just nor sound practice to expand these obligations by legislative fiat. Further, as to future underwriting, the idea that such a massive liability might be created at any future date would certainly chill the most courageous underwriter. This type of sudden liability expansion is more likely to deter the growth of insurance markets than it is to provide a financially sound system of injury compensation; it would therefore defeat its own objectives.

The Study Group majority itself was aware of the problem that an overtly retroactive liability scheme would present; it attempted to circumvent retroactivity to some extent. While its recommended scheme would allow a number of retroactive claims by claimants* against the

---

* Claims could be filed within three years of discovery, whether discovery occurred before or after passage of the implementing legislation. (Report at 209). Further, since discovery of injury might take place many years after the initial exposure to (Footnote continued)

administrative agency (Report at 209-10), it would permit subrogated claims against industry members only for injuries or damages caused by exposure to "wastes disposed of, transported or spilled _after_ the adoption of this proposal. . . ." (Report at 246). However, this is not an effective remedy to the problem of retroactive liability. Industry would end up footing the bill retroactively anyway because, under the Study Group majority's recommendations, unsubrogated claims would be paid through a tax on industry. In all fairness, if society decides to pay such retroactive costs, society in general should foot the bill, rather than attempting to load it unfairly on a small segment of its members.

Further, as we have seen, "toxic torts" may often involve diseases that take as long as 20 or 30 years to develop; claimants may have been exposed to a combination of substances deposited by a number of different companies both before and after implementing legislation is passed. It might be virtually impossible to sort out injury resulting from substances deposited both

---

(Footnote * continued from previous page)
toxic waste, many claims -- and certainly the most catastrophic ones -- would in effect be "retroactive."

before and after the cut-off date, or from substances deposited by different companies. Subrogation suits would thus become an expensive nightmare of claims and cross-claims.* Alternatively, legislative proposals such as the Minnesota Act have permitted suits retroactively unless there is proof that "the substance was placed . . . in or on the facility wholly before" a cutoff date -- in Minnesota the date is set at January 1, 1980.** But for activities that continued after the cutoff date, the Minnesota Act provides extensive retroactive liability as a practical matter, and also fails to solve the problem of cross-claims, thus creating the worst possible "solution."

6. Add-On Remedies

> "[F]ree access to the plenary tort action after the claimant had already had a compensation award on Tier One would be prohibitively expensive from the insurance point of view. A system which called for a binding election between the tort remedy and the compensation remedy

---

* The continued or increased use of joint and several liability of defendants in Tier Two lawsuits would also presumably result in a tangle of cross-claims for contribution in the courts.

** Minn. Stat. § 115B.06(1)(b). The Minnesota Act also provides an additional defense if the substance was deposited prior to January 1, 1973 and defendant's activity was not an "abnormally dangerous" one. Minn. Stat. § 115B.06.

> would be more readily insurable." (View Expressed to the Study Group, Report at 174).

Administrative remedies, in order to be practical, have traditionally involved a trade-off: relaxed standards of proof and easier awards must be balanced by a limitation on the amount recovered. Despite its claims that Tier One is modelled on workers' compensation (Report at 195), the traditional quid pro quo associated with such a compensation system has not been adopted by the Study Group majority's recommendation. Instead, the Study Group majority:

> "adopted the worst of both worlds: an administrative compensation system with liberal evidentiary standards and generous benefits, as well as continued availability of traditional tort law." Office of Management and Budget, Compensation for Toxic Substances Exposure 13 (May 19, 1983).

By providing an administrative recovery with reduced evidentiary burdens for plaintiffs, while doing nothing to provide either a bar or a binding election against further tort claims in court, the Report has gone far beyond the workers' compensation model it claims to follow. Since plaintiffs will typically be seeking large "pain and suffering" awards, which they would not receive in Tier One, the incentive to "go for it" in court would be high. A plaintiff could use his Tier One administrative recovery to fund a subsequent lawsuit in court, thus (in effect) causing the likely defendants to pay the cost of suits against themselves.

The Study Group majority's sole attempt to limit the use of both Tiers by plaintiffs was to permit (but not require) a judge to impose court and expert witness costs on the plaintiff if the plaintiff fails to recover at least 25% more in court than he did in the Tier One administrative proceeding.*

> "Such an assessment, to be made at the discretion of the judge in the plenary court proceeding, is to take into account whether the plaintiff's action was brought in good faith, with a view of avoiding frivolous and duplicatory proceedings." (Report at 202).

In reality, it is doubtful that such costs would be assessed with any frequency. Plaintiffs will usually be individuals of limited means suing defendants who are large corporations; as a practical matter, it would be a rare case in which a judge would find plaintiff's pleading sufficiently frivolous to warrant the imposition of a cost sanction.

---

* A Joint Statement of dissenting Study Group members proposed that once an administrative award was given, claimant should be required to submit to a hearing in court to determine if a lawsuit is warranted, before being allowed to proceed with the lawsuit itself. (Report at 286). Even that system, however, involving yet another hearing, would proliferate legal proceedings and transaction costs. In this regard, consider the view expressed by Study Group Member Jeffrey O'Connell (Report at 354-55) that the three-proceeding structure proposed by the Study Group (i.e., administrative claim, subrogated claim, claimant's lawsuit) was excessive. Mr. O'Connell nonetheless joined in the Joint Statement.

With much to gain and virtually nothing to lose, it is unlikely that many plaintiffs would be deterred from going forward in both Tiers. Thus the Study Group majority's proposal would simply increase the administrative costs of the system overall by adding the Tier One proceedings and administrative costs to the present proceedings and costs of court litigation continued in Tier Two. Such an expensive, cumbersome system lacks any logical support.

V. CONCLUSION

The recommendations of the Study Group majority, and the legislative proposals based on those recommendations, are both unfair and unwise. It makes little sense to rush into such a radical "solution," involving so many pitfalls and draw-backs, as well as staggering costs well in excess of the harm caused. Instead, concerted effort should be devoted to the prevention of such problems in the future, by rigorous enforcement of existing laws, such as the Clean Air Act, Clear Water Act, and RCRA, and by retention of the incentives for proper conduct inherent in the tort system.

In addition, funding should be increased for professionally-conducted studies to determine in a rigorous way what causal links exist between exposure to hazardous substances and the harms claimed to result from such exposure. Once science has established what causal connections exist, there will be little need for Congress or state legislatures artificially to ordain such connections by legislative fiat, or to require compensatory payments from those who are not at fault and not the responsible parties. The American Insurance Association suggests that dispassionate scientific inquiry, coupled with traditional tort law principles assigning liability to those at fault who caused the harm, is the best and most rational means of achieving a just, economic, insurable and workable compensation system for injuries caused by hazardous waste.

TECHNICAL APPENDIX A

Estimation of Average Claim Costs for Workers' Compensation Cancer Cases

The National Council on Compensation Insurance (NCCI) has estimated the current average cost of a worker's compensation cancer claim to be $130,000 based on data for claims which have already been filed, as explained below.

Worker Benefits

A review of reported workers' compensation cancer cases showed that the typical claimant was a fifty year old male who lived for three years after he became disabled and incurred medical expenses approximately equal to his wage loss benefits during that period. The costs of these claims were calculated using current wage rates so that no adjustment for inflation was made.

Survivor Benefits

Existing rules allow for the worker's widow to continue receiving benefits after his death for a duration of up to ten years unless she dies or remarries prior to that time, whereupon benefits cease. Widow's benefits were limited according to these rules using standard mortality tables and the results of an NCCI remarriage study which provided distributions, by age, of the number of women expected to die or remarry in each subsequent year.

COMMENTS OF THE
AMERICAN INSURANCE ASSOCIATION
SUBMITTED BY
M. PATRICIA CASEY TO THE
SUBCOMMITTEE ON INVESTIGATIONS & OVERSIGHT
OF THE
COMMITTEE ON PUBLIC WORKS & TRANSPORTATION
HOUSE OF REPRESENTATIVES
CONCERNING
TOXIC WASTE VICTIM COMPENSATION
HEARINGS OF NOVEMBER 8 & 9, 1983

The American Insurance Association was pleased to be present at the testimony concerning the activities of states on hazardous waste legislation and concerning the scientific problems involved in the compensation issue. It is pleased to present its comments on the testimony heard by the Subcommittee.

The American Insurance Association is a trade association composed of 170 publicly owned insurance companies providing property and casualty coverages. The Association's members provide the majority of general commercial liability insurance in the United States. It is likely that members of the American Insurance Association will provide insurance for those subject to liability for hazardous substance compensation.

Our members have been instrumental in helping to shape the financial regulations under the Resource Conservation & Recovery Act and have been represented at the state legislative level also. A market for insurance to cover liabilities from pollution incidents can develop only if the liabilities to be insured are reasonably predictable and affordable. Since the members of the American Insurance Association have responded in the past to emerging liabilities, the Association is interested in proposals concerning new liabilities.

The American Insurance Association applauds the efforts of the Subcommittee on Investigations & Oversight to review the activities at the state level. In the past two years, our Association has seen that state legislative activity has expanded greatly in this area in response in part to the increased awareness of the public to the dangers of hazardous substances. The laws in Minnesota, California and North Carolina are representative of the significant interest and hard work by those state legislators.

Insurers can underwrite only liabilities which manifest some degree of predictability. They do not insure unlimited exposures. Yet currently, very little data on pollution claims, their frequency and severity, exists to assist underwriters in assessing the risk.

Given the problems involved in underwriting pollution coverages, the members of the American Insurance Association and other insurers strongly opposed the enactment of Minnesota's Environmental Response & Liability Act about which Representative Long testified on November 8. Our Association urged the Governor to veto Minnesota's Environmental Response & Liability Act in a letter dated May 2, 1983 (copy attached). T. Lawrence Jones, President of the American Insurance Association, in that letter wrote:

> "Our member companies, as well as the insurance industry as a whole, have responded to the need for coverage for environmental harms through the environmental impairment liability coverage. Our Association has been heavily involved with the consideration of environmental issues at state and federal levels. We are strongly supportive of enforcement of laws to

> protect our environment and our public's health. We believe absolutely that prevention of harm to the environment is essential. During the past two years, our member companies have responded to the new challenge; they have entered the environmental liability market, and developed new insurance policies, including a policy covering gradual contamination. They have aggressively marketed this coverage."

He objected to the extensive liability provisions which would severely curtail the developing insurance market for environmental harms. He noted:

> "Among other provisions, the Conference Committee proposals contain a presumption of causation so vague and sweeping that it would eliminate the predictability of claims against specific insureds needed by underwriters. The Conference Committee proposal would also retroactively apply a standard of strict, joint and several liability for unprecedented personal injury and property damage without limits. Even the federal Superfund, which contains extensive liability provisions for property damages, provides for maximum limits of liability."

Further, he informed the Governor that:

> "Our member companies have informed me that should the Conference Committee proposals become law, many of them will consider severely restricting their current policies in the State of Minnesota. Because of the effect of unpredictability and unlimited liability which this legislation would have on the market, companies at all willing to write this coverage may have to make it so expensive as to be prohibitive, especially for small and medium sized customers."

Since that time, some companies have already decided they will not provide this coverage. Other companies are reviewing their position. We do not know of any company that currently provides coverage under Minnesota's enactment.

The American Insurance Association feels that it is important to correct some of the misperceptions of our industry contained in Representative Long's testimony. Ms. Long quoted extensively from William Mahoney, Vice President of the brokerage company Marsh & McLennan, from a presentation he made on May 23, 1983. At that time, Mr. Mahoney stated that the capacity for coverage of pollution liabilities was not a problem and that it was indicated that the "entire insurance industry - from the primary placement up through the excess layers - will be ready and willing to accept pollution liability insurance risks." Mr. Mahoney was speaking about the general market for pollution, particularly gradual pollution coverages, and his remarks were not intended to characterize the market in Minnesota after the enactment of the Minnesota Environmental Response & Liability Act.*

The Minnesota Environmental Response & Liability Act represents a significant expansion of tort law liabilities. The liabilities under that Act are extensive as well as ill-defined. As you are aware, insurers need to know the boundaries of their liabilities in order to properly price the risk, to reserve sufficient loss amounts, and naturally to attempt to provide some profit for the benefit of their shareholders. Two provisions of the Minnesota law present such formidable obstacles to our underwriters that we urge you not to consider proposing similar provisions in any federal proposal.

First, the cause of action created by that legislation will allow the award of almost unlimited damages using the standard of strict, joint and several liability on a retroactive basis. While the law states [illegible] personal injury cause of action cannot be sought if the release or threatened release occurred "wholly before" the effective date of July 1, 1983, the law as we read it is almost indefinitely retroactive. It will be difficult for any defendant to prove, particularly with regard to groundwater contamination, when a release or threat of release began or had wholly occurred. Also, since the law contains a provision under which the judge appears able to assign accrual of the cause of action at almost any point, this adds to the concern about the retroactive application.

---

* In a telephone conversation on November 21, 1983 with Mr. Mahoney, he stated that he "never addressed the victim's compensation act at all," and that his remarks were taken out of context by Ms. Long. He said he was only addressing the issue of availability of environmental impairment liability coverage for those companies seeking to purchase insurance.

The second problem for insurers is the provision relating to causation. The November 8 and November 9, 1983 hearings before your Subcommittee contained many references to the issue of causation. This issue is of paramount concern to insurers as it triggers the involvement of the insurance industry. We noted that some speakers on November 8 urged enactment of legislation to weaken the burden of proof of causation. Insurers are gravely concerned about the weakened causation provisions in the Minnesota law. Section 7 of that Minnesota law would prohibit a judge from directing a verdict against a plaintiff if the plaintiff could show that he was exposed to "the" hazardous substance, that the release "could" have resulted in the plaintiff's exposure, and that the injury was caused or significantly contributed to by exposure to "the" substance. This section amounts to a presumption of causation in favor of the plaintiff.

As Leslie Cheek, Vice President of Crum & Forster, pointed out to the Minnesota legislators, there is no requirement that plaintiff's exposure was to the particular hazardous substance of the particular defendant. Further, that provision states that "evidence to a reasonable medical certainty that exposure to the hazardous substance caused or significantly contributed to the death, injury or disease is not required for the question of causation to be submitted to the trier of fact." Mr. Cheek, in his testimony to the Minnesota legislature, pointed out that this opens the question of what, if anything, is required as the plaintiff's burden of proof on the issue of causation. As the damages for which a plaintiff could sue include not only medical expenses and loss of income but any loss of past or future profits, any damages for pain and suffering, as well as damages to the national resources, insurers are justifiably concerned about their exposures if they try to provide pollution coverage.

We submit that intelligent efforts to define environmental liabilities in a reasonable manner will result in an insurance market which can assist in the compensation of individuals harmed through hazardous substances. Our industry has an interest in marketing pollution coverages and is in fact trying to grapple with some of the complexities in this area through task forces and intra and inter-industry research.

Our industry is complex and many faceted. Statements are easily taken out of context. As an example, Ms. Long called your attention to the paper prepared by R. J. Taylor of the brokerage company Fred S. James and seemed to cite it as presenting a favorable view of the Minnesota Act. That study merely compared the then proposed Minnesota bill to the Federal Superfund. While that study stated that it is important to keep in mind that not all liability created under the Federal Superfund is currently insurable, it concluded that the enactment of state legislation such as the Minnesota bill will not "in itself make insurance coverage unavailable to all risks within the state" (report at pages 4 and 17). This does not constitute a representation that insurance under that law would be available and affordable.

The American Insurance Association believes that in fact, the coverage is not.

The American Insurance Association appeared before the North Carolina Governor's Waste Management Board to discuss liability issues relating to the hazardous waste industry. Their 1982 Annual Report with recommendations showed that members of the Board had studied the issues in depth. Notably, with respect to the issue of concern to your Subcommittee, the Board concluded that it was premature at this time "to assume that the volume or complexity of hazardous waste liability cases will be so great that the general court system cannot handle them adequately (report at page 56). Further, the Board noted that implementation of a stringent regulatory program should reduce the potential for injuries. AIA supports this regulatory conclusion.

The Subcommittee is to be commended for its attempts to have present scientists involved with hazardous substances from the Centers for Disease Control, the National Institute for Occupational Safety & Health, and the National Science Foundation, as well as for its open-mindedness toward the opinions of the chemical industries such as those represented on November 9 by Union Carbide and the Atlantic Richfield Companies.

Insurance is indeed only a part of the solution to the problem involving hazardous substances and compensation for losses. Yet, as Mr. Kusch of Atlantic Richfield pointed out, it is not an insignificant factor in considering how to compensate persons, property and the environment. Accordingly, we would urge you to consider the limitations of our industry as well as the desire of our industry to provide a market for compensation. The American Insurance Association appreciates the opportunity to be involved in the legislative process. We previously forwarded to you our position paper in response to the 301(e) study developed with the assistance of Sheila Birnbaum of New York University and we would be pleased to answer any questions that you might have at any time.

Respectfully submitted,

M. Patricia Casey

AMERICAN INSURANCE ASSOCIATION
85 JOHN STREET
NEW YORK, N.Y. 10038
(212) 669-0400

VIA POST OFFICE EXPRESS MAIL

May 2, 1983

The Honorable Rudy Perpich
Governor
State of Minnesota
State Capitol
St. Paul, Minnesota 55155

Dear Sir:

I am President of the American Insurance Association, a trade association of 165 stock property and casualty insurers. Many of our members do business in Minnesota. They greatly value their Minnesota clients.

Our member companies, as well as the insurance industry as a whole, have responded to the need for coverage for environmental harms through the environmental impairment liability coverage. Our Association has been heavily involved with the consideration of environmental issues at state and federal levels. We are strongly supportive of enforcement of laws to protect our environment and our public's health. We believe absolutely that prevention of harm to the environment is essential. During the past two years, our member companies have responded to the new challenge; they have entered the environmental liability market, and developed new insurance policies, including a policy covering gradual contamination. They have aggressively marketed this coverage.

However, underwriters currently have little data available because this coverage is brand new. They must base the premium charged on their best analysis of the risk, and the existing parameters of common law liability.

Reliable reports of the proposed provisions from the Joint Conference Committee pertaining to H.F. 76 and S.F. 220 indicate that the Minnesota Legislature is seriously considering enacting a novel liability structure for those engaged in the hazardous waste industry. If enacted, it will severely curtail the young insurance market which is now forming to cover environmental harms.

Among other provisions, the Conference Committee proposals contain a presumption of causation so vague and sweeping that it would eliminate the predictability of claims against specific insureds needed by underwriters. The Conference Committee proposal would also retroactively apply a standard of strict, joint and several liability for unprecedented personal injury and property damage without limits. Even the federal Superfund, which contains extensive liability provisions for property damages, provides for maximum limits of liability.

The issue of compensation for bodily injury and property damage arising from hazardous waste related incidents is of national importance. It is being considered and debated by academicians, state and local councils, national task forces, and industry. The scientific analysis of the problem and its extensiveness is only just beginning. Nevertheless, insurers have been willing to enter the market despite not knowing the full dimensions of the issue because they so far found market conditions sufficiently reasonable to underwrite.

Our member companies have informed me that should the Conference Committee proposals become law, many of them will consider severely restricting their current policies in the State of Minnesota. Because of the effect of unpredictability and unlimited liability which this legislation would have on the marker, companies at all willing to write this coverage may have to make it so expensive as to be prohibitive, especially for small and medium sized customers.

When you receive this bill, we strongly urge that you veto it.

Sincerely,

T. Lawrence Jones
President

Proceedings
American Medical Association
House of Delegates December 1981

REPORTS OF COUNCIL ON SCIENTIFIC AFFAIRS

The following reports, A–G, were presented by William D. Dolan, M. D., Chairman:

A. HEALTH EFFECTS OF "AGENT ORANGE" AND DIOXIN CONTAMINANTS

(Reference Committee E, page 282)

HOUSE ACTION: ADOPTED

The American Medical Association's Council on Scientific Affairs, in response to a request from the Medical Student Section, has reviewed the medical evidence regarding the toxicity and long-term health effects of Agent Orange and its associated contaminant 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD). This Executive Summary, which was prepared by the Council on Scientific Affairs Advisory Panel on Toxic Substances,* summarizes the findings in its Technical Report on the subject, which is available on request.

BACKGROUND

During the latter stages of the United States' involvement in Vietnam, herbicidal mixtures of 2,4-dichlorophenoxyacetic acid (2,4-D) and 2,4,5-trichlorophenoxyacetic acid (2,4,5-T), otherwise identified by the military as Agent Orange, were sprayed over certain areas of Vietnam for the express purpose of defoliating the jungle and destroying one of the enemy's means of concealment. Similar spray programs have been used in the United States as a means of forestry management. For the past thirty years, mixtures of 2,4-D and 2,4,5-T have been used extensively by the home-owner and farmer for ridding lawns and agricultural acreage of unwanted broadleaf vegetation. Large numbers of persons have been exposed to varying amounts of 2,4-D and/or 2,4,5-T, as well as the contaminant 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD), in the normal course of employment.

Also over these years, there has been a number of industrial incidents wherein workers, as well as civilian populations, have been subjected to accidental exposure to these compounds. There are now pending a number of litigious actions and government regulatory responses that are based upon alleged adverse health effects from such exposures.

The most serious of these allegations by Vietnam veterans and persons who were involved in accidental industrial exposures assert that Agent Orange, or compounds of a like nature, may have caused malignant tumors, sterility, spontaneous abortions, birth defects, disfiguring skin diseases and other illnesses. In spite of the voluminous data on the biological effects of the phenoxy-type pesticides and the associated chlorinated dioxins, there is still very little substantive evidence for the many claims that have been made against these compounds. Data from experimental animals do indicate that TCDD is a toxic material; however, while suggestive, the animal data are not necessarily applicable to man. Still, a number of those exposures to TCDD of industrial and general populations that have occurred have been sufficiently well documented to offer some insight into the effect of TCDD on man.

Agent Orange, or Herbicide Orange, was a label given by the U. S. military forces to a 50:50 mixture of the n-butyl esters of 2,4-D and 2,4,5-T together with a minor amount (1%) of the free acid of 2,4,5-T and varying amounts of the contaminant TCDD. Agents Green, Pink and Purple also were used as defoliants by the military forces from 1962 through 1964; a time when very few American troops were committed to the field. Another formulation, Herbicide Orange II, was similar to Agent Orange except that the isooctyl ester of 2,4,5-T was substituted for the n-butyl ester of 2,4,5-T. In addition to Agent Orange, other spray defoliants used in Vietnam included Herbicide White, whose active ingredient was picloram (or the tri-isopropanolamine salt of 4-amino-3,5,6-trichloropicolinic acid). This substance is very persistent in the environment and highly carcinogenic in rats and mice. Lesser amounts of Herbicide Blue, which contained sodium cacodylate* (26%) and cacodylic acid (5%), were used. Though the long-term effects in humans of either or both of these compounds is uncertain, picloram and cacodylic acid should be considered along with the above agents that were encountered in Vietnam.

---

*John R. Beljan, M. D.; Nelson S. Irey, M. D.; Wendell W. Kilgore, Ph. D.; Kazuo Kimura, M. D., Ph. D.; Raymond R. Suskind, M. D.; Jaroslav J. Vostal, M. D., Ph. D.; R. H. Wheater, M. S., Secretary

TCDD may form as a by-product of the synthesis of 2,4,5-trichlorophenol (TCP), a precursor of 2,4,5-T, when 1,2,4,5-tetrachlorobenzene is subjected to alkaline hydrolysis at elevated temperature and pressure. If the reaction temperature is allowed to go above 180° C, the sodium-2-hydroethoxide (formed from the ethylene glycol solvent and caustic soda) decomposes exothermically and promotes the dimerization of sodium trichlorophenate to TCDD. The presence of TCDD as a contaminant of 2,4,5-trichlorophenol was discovered in 1957, when workmen involved in the manufacture of TCP developed chloracne.

About twenty years ago, commercially available 2,4,5-T contained anywhere from 1 to 70 ppm of TCDD. When the industry became aware of the contaminant's existence and toxicity, production operations were monitored and altered to reduce the level. Current manufacturing operations are able to control the amount of TCDD in commercial 2,4,5-T formulations to less than 0.01 ppm (with occasional batches as high as 0.05 ppm), a level believed to be non-hazardous to humans and other organisms. Data relating to an acceptable maximum level are presently under regulatory review by FIFRA (Federal Insecticide, Fungicide and Rodenticide Act); the recommended maximum concentration is now placed at 0.1 ppm.

Commercial formulations of 2,4,5-T and 2,4-D were used safely in agriculture for over thirty years with no recognizable evidence of carcinogenicity or birth defects in humans. Those adverse effects that did occur from massive doses of either pure 2,4-D or pure 2,4,5-T were manifested soon after the exposure, and the victims recovered with no signs of long-term damage. When the first symptoms were to present months or years after the last exposure to these compounds, it was evident another causal agent had to be responsible. That agent was later suspected to be TCDD. Though closely related chemically to 2,4,5-T, 2,4-D is not generally contaminated with TCDD.

BIOLOGICAL EFFECTS

Two of the more pronounced biological effects of some of the clorinated dioxins are their tendency to cause chloracne (especially, in the rabbit, nude mouse, monkey and man) and the accumulation of fluid (ascites) in the pericardium and peritoneal cavity of chicks.

Chloracne in man is typified by comedones in a malar distribution; the pre- and postauricular portions are often accompanied by hirsutism and sometimes by melanosis and a secondary inflammation. The disease was first described in 1899; its cause was discovered in 1918 to be due to contact with certain clorinated hydrocarbons. Chloracne has now become one of the more common forms of occupational dermatitis. Other acute toxic reactions to dioxin include liver and renal damage, porphyria cutanea tarda, hyperpigmentation, hirsutism, polyneuropathies (e.g., sensory impairments and weakness in lower extremities) and neurasthenic or depressive syndromes. Thus far, long-term effects, except for persistent chloracne, have not been seen.

Chloracne is not caused by 2,4,5-T and 2,4-D per se; if the condition occurs upon exposure to either or both of these compounds, it is most likely that the contaminant TCDD is responsible. Chloracne usually appears within 2 to 3 weeks after the first exposure. Mild chloracne clears up within several months after cessation of exposure; severe chloracne, on the other hand, has been known to persist for as long as thirty years following the last exposure. Persons more responsive are those who are prone to develop acne vulgaris. If one's exposure to TCDD is severe enough, cysts form and, on occasion, inflammation and scarring will occur. If there is no medical history of chloracne, then the likelihood of a significant exposure to, or adverse health effects from, TCDD is remote. Hence, chloracne is the clinical marker of TCDD exposure.

Chronic exposures to TCDD lead to degeneration of the liver and thymus in experimental animals; one sensitive index of exposure is atrophy of the thymus. Porphyria, altered levels in serum enzymes and weight loss are also observed. Major organs to be affected are the liver, blood forming organs and the reticulo-endothelial system. Progressive weight loss, the first clinical sign of toxicity in the monkey, may be accompanied by alopecia, facial edema and a dry, scaly dermatitis over the rest of the body.

---

*Sodium cacodylate is the sodium salt of cacodylic acid (hydroxydimethylarsine oxide)

The metabolism of TCDD in man is unknown, and for the present there is only limited information available on the metabolic pathways and metabolites that may occur in other mammals. TCDD is distributed equally among the fat and liver of mammals, to a lesser extent in the kidneys, and is eliminated via the feces. Samples of fat from beef cattle and samples of milk from cows that had grazed on 2,4,5-T-treated pasture or rangeland, in addition to human milk from an area where 2,4,5-T herbicides were used repeatedly over a period of twenty years, had small to undetectable (not more than 10 ppt) amounts of TCDD.

No clearly defined mutagenic effect has been observed in vitro with TCDD. TCDD does induce genetic changes by the Ames test with S typhimurium and E coli but not with repair-defective strains; there is no evidence (from dominant lethal and cytogenetic evaluations in rodents) that such changes occur in whole animals.

Of perhaps more relevance to man are the in vitro studies on mammalian cells – i.e., HeLa; Balb-3T3, normal mouse fibroblasts; SV101, virus (SV40) – transformed 3T3 mouse fibroblasts; human foreskin fibroblasts; and normal human lymphocytes. No significant growth inhibition in the cell cultures nor discernible ultrastructural changes have been observed by electron microscopy.

The teratogenicity and fetotoxicity of TCDD were discovered in 1969, in the course of a study on the biological activity of 2,4,5-T. The sample being used was later found to be contaminated with TCDD. The incidence of cleft palate was greater in two particular mouse strains (C57BL/6 and AKR), while the C57BL/6 mouse and the rat developed a higher incidence of cystic kidney. All doses given the rat led to gastrointestinal hemorrhage in the fetus. The increased ratio of fetal liver to body weight in the mouse suggested that TCDD was fetotoxic in this particular species.

A majority of studies using high doses of 2,4,5-T with 0.1 ppm of TCDD or less showed cleft palate in mice, but no other species, and embryotoxicity in the mouse, rat, hamster, sheep, monkey and rabbit. There is no scientific evidence that 2,4-D, 2,4,5-T or TCDD has caused reproductive difficulties or hazards in the human. No conclusive evidence is yet available that phenoxy herbicides or TCDD are mutagenic or teratogenic in man.

TCDD can induce cancer or serve as a cancer promoter in some strains of rats and mice. In contrast to some other chemical carcinogens, the carcinogenicity is always accompanied by considerable systemic toxicity.

From an environmental view, TCDD breaks down rapidly on leaves of plants, in water and on the surface of soil, especially through the action of sunlight. In soil it generally has a half-life of about 230 days; some soil microorganisms can degrade it, especially if other chlorinated hydrocarbons are present.

EXPERIENCE IN MAN

One of the most extensive human experiences with the adverse effects of TCDD in man involves the residents of Seveso, Italy. In July of 1976, TCDD was accidentally released from the ICMESA* trichlorophenol synthesis plant when a safety disk in a steam-heated reactor vessel ruptured. The plume of reactor contents, including TCDD, rose 160 feet above the factory and fell in a cone-shaped pattern about a mile long and a half-mile wide. This is the largest single population to have been exposed to the compound. Over 37,000 persons were potentially exposed to varying doses.

Two years after the incident occurred, the acute and mid-term health effects were assessed; the mild chloracne, which occurred mainly in a small group of children, healed quickly. Subclinical peripheral nerve impairment was reported; there was also some liver involvement, but without apparent functional disorder. Neither immunoresponse nor susceptibility to infectious diseases was altered.

---

*Industrie Chimiche Meda Societa Anonima

The most recent progress report on the long-term epidemiologic survey of the residents of the Seveso area emphasizes the preliminary nature of their findings and reiterates the conclusions of prior investigators. Except for the skin, no organs or body functions were impaired. No derangement of gestation, no fetal lethality and loss, no gross malformations, no growth retardation at term and no cytogenetic abnormalities have yet occurred.

The first of several accidental releases of TCDD and other dioxins, attending the manufacture of 2,4,5-trichlorophenol (TCP) or 2,4,5-T occurred in 1949 in the United States. At least 11 other industrial accidents or exposure incidents have occurred since then, both here and abroad. To date, an estimated 579 workers are known to have been exposed, including 156 employees in the ICMESA plant at Seveso.

CURRENT STUDIES

There are now a number of studies underway by agencies of the U. S. government and industry, which may resolve questions on the kinds and extent of human damage from exposure to low levels of TCDD:

> Through its Department of Environmental and Drug-Induced Pathology, the Armed Forces Institute of Pathology (AFIP) is examining biopsy and autopsy tissue of all Vietnam veterans. To date, only 152 cases have been assessed: the dominant diseases are epidermal inclusion cysts and chronic, non-specific dermatitis. If any malignancies were to have been induced by TCDD, they should be appearing by now, yet there have been no unusual morphological features nor clustering of tumors by diagnosis or site as to implicate Agent Orange.
>
> A soft-tissue sarcoma study also has been proposed that will be conducted jointly by the Armed Forces Institute of Pathology and the National Cancer Institute.
>
> The Air Force, through Project Ranch Hand, will administer and examine the 1,200 personnel who were involved in the actual handling and spraying of Agent Orange. They, and the control population of 20,000, are to be followed over the next twenty years.
>
> The University of California, Los Angeles, was awarded a contract by the Veterans Administration for the design of an epidemiologic study of Vietnam veterans.
>
> Approximately 45,000 Vietnam veterans who expressed concern about the hazards of Agent Orange have been examined by the VA; data on 25,000 of these men have been placed in a special Agent Orange Registry, which may serve later to identify them and to provide medical information as well as indications of health trends over the long term.
>
> The Chloracne Task Force was established to sift out those cases of dermatitis that either resemble or are truly chloracne. Cases of the former type will be reexamined by dermatologists who have an expert knowledge of the disease. Thus far, there are only 700 cases of "skin conditions" out of the total of 3,500 filed claims for damage from Agent Orange.

RECOMMENDATIONS:

The Council on Scientific Affairs recommends that:

1. The above studies on exposed, or allegedly exposed, persons continue to be supported and, if feasible, enlarged to include the cooperative engagement of all internationally known exposure data, as recommended by the International Agency for Research on Cancer (IARC).

2. All physicians be alerted through AMA publications to the classical signs of chloracne and the possible signs and adverse effects of TCDD exposure. They should be encouraged to enlist in the present efforts to identify and treat those persons who have had serious exposures to TCDD, and to cooperate in the collection of vital information that is needed for the ongoing human epidemiologic studies.

James

AVAILABILITY OF POLLUTION LIABILITY INSURANCE UNDER PROPOSED STATE SUPERFUND LEGISLATION

Prepared by: Rodney J. Taylor, J.D., P.E., CPCU
Vice President
National Services Division
Fred. S. James & Co., Inc.
230 West Monroe Street
Chicago, Illinois 60606
(312) 726-4080

March 25, 1983

AVAILABILITY OF POLLUTION LIABILITY INSURANCE UNDER PROPOSED STATE SUPERFUND LEGISLATION

A. INTRODUCTION

This report considers the impact which enactment of proposed state legislation to establish environmental response, cleanup and liability programs similar to the federal Comprehensive Environmental Response, Compensation, and Liability Act of 1980 (Superfund) may have on the availability and cost of insurance coverage for pollution liability. More specifically, Minnesota Bill H.F. No. 76, known as the "Environmental Response and Liability Act" was reviewed to determine whether its provisions create new sources of potential liability which differ sufficiently from those which exist under current state and federal environmental laws and from those present under common law to present a problem from the standpoint of insurability. Of course, the issue of whether insurance coverage can be obtained for a given risk is only one of the many factors which the legislature considers in deciding whether a particular piece of legislation should or should not be enacted. But state congressmen are sensitive to the impact which proposed legislation will have on business and industry within the state and in light of the current depressed economy, they do not want to enact measures which will cause their state to lose industry to other regions where less restrictive laws apply. If a certain piece of legislation contains provisions which could result in substantial liability to industry, the legislature will be interested in whether the potential liability can be managed by the purchase of insurance coverage.

H.F. No. 76, if enacted, is legislation which could result in substantial liability on the part of those industries affected by its provisions. This group of affected industries is relatively large since it includes any organization or entity that uses, generates, stores, treats or disposes of hazardous substances or is otherwise responsible for the release of such materials into the environment. The potential liability could also be relatively large since H.F. No. 76 provides for the cleanup of spilled materials, the payment of claims for personal injury and property damage, including claims for the loss of use of property and loss of profits, and relocation of persons threatened by a release. The recent cases involving pollution liability indicate that the exposure from such claims can run into hundreds of millions of dollars.

The question of what impact proposed legislation may have upon the availability of pollution liability insurance is not an easy one to address. Regardless of what logical process one applies to make such a determination, there are factors which affect the marketplace which cannot be adequately considered in advance of the actual enactment of the new law. The insurance market is not static, changes in interest rates, underwriting losses and natural disasters may change the operating philosophies of the insurance companies overnight. With the existing "soft" market for most liability coverages, it may be possible to insure certain risks today, but not be able to guarantee the availability of insurance in the future.

In considering whether Minnesota H.F. No. 76 would have a significant impact on the ability of industry within the state to purchase pollution liability insurance, it seemed logical to consider how much "new" liability would be created by enactment of this legislation and to analyze the factors considered by underwriters in offering environmental damage coverages to see which might be affected by the provisions of the proposed legislation. One way to evaluate the "new" liability is to compare Minnesota H.F. No. 76 with the federal Superfund legislation, which has been in effect since 1980. This is done in Section B of this report which also notes the liability which exists at common law where it would apply in addition to or instead of Superfund.

It is important to keep in mind that not all liability created by Superfund is currently insurable under Comprehensive general liability (sudden) or environmental impairment liability (gradual) insurance policies. Noteworthy exclusions include the cost of cleanup of non-owned sites where the insured has disposed of materials and damage to or cleanup of the insured's premises. It is important to recognize that insurance cannot solve all of the problems associated with the disposal of hazardous substances. The current crisis in waste disposal in this country is a complex problem brought about by many factors including decades of improper disposal practices. These problems will only be resolved by decades of attention to correcting past errors and a significant financial commitment to restoring what has already been damaged. Insurance for pollution liability may be a part of the solution to these problems, but it obviously is only a small part.

B. DIFFERENCES BETWEEN NATIONAL "SUPERFUND" AND MINNESOTA ENVIRONMENTAL RESPONSE & LIABILITY ACT (H.F. NO. 76)

1. Of greatest significance is the fact that H.F. No. 76 creates a cause of action by third parties alleging property damage, personal injury and environmental damage as a result of a

release or threatened release of a hazardous substance, pollutant or contaminant by a responsible person. Under "Superfund", the government may cleanup a spill or site from which a hazardous substance is released (or where a release is threatened) and recover the costs of removal and remedial actions but there is no new right on the part of third persons to bring an action against the person responsible for the release.

a. Section 5 of H.F. No. 76 allows recovery of the following:

  1.) Actual economic loss, including:

    a.) Injury to or destruction of real or personal property, including relocation costs;

    b.) Loss of use of real or personal property; and

    c.) Loss of past or future profits resulting from injury to or destruction of real or personal property. (Without regard to ownership).

2.) All damages for death or personal injury or disease, including:

a.) Medical expenses, rehabilitation, costs of burial expenses;

b.) Loss of past or future profits resulting from personal injury or disease; and

c.) Damages for physical impairment, loss of earning capacity or other pain and suffering.

b. These costs may, of course, be sought in a common law action, but the liability would not necessarily be strict, joint and several as is provided for in Subdivision 1 of Section 5.

2. The recovery of removal and remedial costs provided for in Section 4 of H.F. No. 76 is stated to be strict, joint and

several. Under Superfund, the EPA has been operating under the assumption that liability is strict, joint and several, but this is not specifically stated.

a. The "persons responsible" section of H.F. No. 76 (Section 3, Sub. 1) appears to be equivalent to the liability section of the Superfund Legislation (Section 107 (a)) in other respects.

b. Under Superfund, Section 107 (c) (1) limits liability of responsible persons, except for removal costs, to amounts specified - $50,000,000 for most land-based treatment, storage or disposal facilities. The damages to natural resources and economic damages, including loss of use of property and loss of profits are unlimited under H.F. No. 76, as well as remedial and removal costs.

1.) From a practical standpoint, the common law cases seeking recovery for environmental damage are not limited either. For example, if all claims being sought against Hooker Chemical for releases at Niagara Falls, New York were successful, the company would owe $26.4 billion to third parties claiming personal injury, property damage and other economic or non-economic loss. There are, of course, ways to insure risks which can produce unlimited liability through specifying limits and self-insured retentions in the policy which are acceptable to the underwriters.

2.) Defenses available to a responsible party (Act of God, act of war or act of a third party) are the same under H.F. No. 76 (Section 4, Sub. 6) as under Superfund (Section 107 (b)).

3. Section 107 (c) (3) of Superfund allows imposition of punitive damages in an amount up to three times the costs incurred by the Fund as a result of any release or threatened release where the responsible person fails to provide removal or remedial action upon order of the President. Section 17 of H.F. No. 76 provides for a civil penalty of not more than $10,000 per day for each day that the responsible person

fails to take response actions or fails to make reasonable progress in completing response actions requested.

4. H.F. No. 76 provides a retroactive cut-off date, making the liability provisions applicable only to a release or threatened release which occurs on or after July 17 1983, including a release which began before that date and continues afterwards. (Section 13). There is also a limitation on the application of strict liability for releases where the responsible person can establish that the hazardous substance involved was placed in the facility on or before April 1, 1982 and that the imposition of strict liability would be unfair. These limitations are not especially helpful from the standpoint of underwriters considering insuring this risk since most gradual releases are continuous and when they result in a claim are still continuing. Even where strict liability is not applicable, liability based on common law grounds and subject to normal defenses may still be established. This potentially extends the underwriters' liability far back to past operations when the risk was neither clearly understood nor adequately evaluated.

a. This backward extension of liability for past operations under H.F. No. 76 is no different from that

X

under Superfund, except that the liability under H.F. No. 76 includes third party actions which are not provided for under Superfund.

b. There is a potential problem for CGL underwriters under H.F. No. 76 for claims brought under an occurrence-basis policy where the causal connection between an exposure and injury was not established at the time of a sudden and accidental release, but is later determined. With the statute of limitations provision of H.F. No. 76 (Section 10) allowing a claim brought within six years from when the plaintiff discovers a causal connection between the injury, disease or loss and the release of a hazardous substance, this could, for example, result in a claim against the underwriter on an occurrence-basis CGL policy where a release occurred in 1965 or before, but the disease does not manifest itself until 1980 or later and a causal connection is not established until 1983. The claim could be brought any time through 1989.

c. Gradual pollution policies (EIL) are being offered only on a claims-made basis, which means that the current insurer accepts responsibility for all claims which manifest themselves after inception of the current policy period, regardless of when the release took place so long as it continues into the policy period. The liability provisions of H.F. No. 76 should not be any more difficult to underwrite than common law gradual pollution liability, at least with respect to the retroactive liability feature.

d. "Remedy" and "remedial action" definitions are the same in H.F. No. 76 (Section 2, Sub. 14) and Superfund (Section 101, Paragraph 24). Both provide for remedial actions including storage, confinement, perimeter protection, clay cover, neutralization, cleanup, recycling, reuse, etc., and the permanent relocation of residents, businesses and community facilities.

e. "Remove" and "removal activities" under both H.F. No. 76 (Section 2, Sub. 15) and Superfund (Section 101, Paragraph 23) include provisions of alternative water supplies in addition to cleanup and removal of released hazardous substances. In both, this liability is unlimited.

5. The "Apportionment" provision of Section 8 allows a person found jointly and severally liable under H.F. No. 76 to seek apportionment from other parties who may also be liable for a release or threatened release. This is not addressed specifically in Superfund since strict liability is not a part of the Superfund legislation.

   There is nothing new about the concept of apportionment. It is a common law principle which is allowed in any case where joint and several liability is found and a recovery is sought by the claimant from one or more, but not all parties found liable. This feature of H.F. No. 76 should not have a negative impact on the interest of underwriters in offering gradual pollution coverage to risks in Minnesota.

6. Section 7 of H.F. No. 76 prohibits a directed verdict on the issue of causation and permits the trier of fact to draw the inference that death, injury or disease was caused or significantly contributed to by the release of a hazardous substance if it is established that:

13

a. the substance was released from a facility under circumstances which could reasonably result in exposure of the person to the substance;

b. the person was exposed to a hazardous substance which is the same as that released from the facility;

c. the person suffered death, injury or disease which is known to be caused or significantly contributed to by the hazardous substance to which the person was exposed and by the amount and duration of the exposure.

While this provision has no parallel in Superfund, it should not present a serious problem for liability underwriters considering offering gradual pollution coverage in Minnesota. * The provision only prohibits a directed verdict on the issue of causation where the conditions outlined are met and allows, but does not require an inference that there is a causal link between the release of a hazardous substance and death, injury or disease where the other conditions are present. Since Paragraph (c) requires that the death, injury or disease is known to be caused or significantly contributed

14

to by the substance involved in concentrations and for durations actually encountered, the applicability of Section 7 should be quite limited. Most diseases, injuries and deaths are only thought to be caused or contributed to by exposures to toxic substances and the proof of causation in fact is not an easy burdle to overcome.

*

7. Section 15, Subdivision 2 requires recording a special notice of potential hazards on the title of any real property where hazardous substances have been deposited. The use of such land is also restricted to activities which do not disturb the integrity of the storage facility. This provision provides for civil penalties of up to $100,000 for violations of the recording requirement and makes the property owner, who fails to record an affadavit, responsible for any release or threatened release from the facility.

   a. This provides potentially new causes of action for property owners with respect to alienated properties. There have, however, already been actions in which real estate contracts have been rescinded as a result of an owner's failure to disclose that the site had been used for disposal of hazardous substances. The common law grounds for such an action include breach of an implied warranty of fitness for a specific purpose and negligent misrepresentation, as well as willfull concealment of material information concerning the site.

C. ANALYSIS OF FACTORS CONSIDERED IN OFFERING INSURANCE FOR ENVIRONMENTAL EXPOSURES INCLUDING THE LIABILITY ARISING UNDER THE PROVISIONS OF MINNESOTA H.F. NO. 76

Underwriters considering the insuring of environmental exposures associated with either the gradual or sudden release of harmful substances, evaluate the following factors to determine whether a risk is insurable and, if it is, what such coverage will cost:

1. Type and quantity of hazardous substances used, generated, treated, stored or disposed of by the prospective insured;
2. How these materials are being used, stored, transported, transferred and disposed of;
3. Whether operations involving hazardous materials are properly segregated from other non-hazardous activities;
4. Whether employees are well trained in how to handle hazardous

14

substances and in responding to emergency situations involving a release or threatened release;

5. The attention given to engineering factors designed to prevent a release and to contain materials which may be released;

6. Attention given to preplanning for emergencies involving hazardous substances, including the availability of neutralizing and absorbing materials;

7. Past history of the prospect with respect to environmental claims and violations of environmental regulations;

8. Environmental pathways by which harmful substances can migrate from the insured premises to the property of others; and

9. The nature and proximity of the surrounding population and its sensitivity to damage as a result of exposure to the materials used or generated by the insured.

Whether liability arises under common law theories of negligence, nuisance, trespass and use of ultrahazardous substances or any of] * the dozens of statutes designed to protect the environment is not the major consideration of the underwriter. A well-run facility that scores high in the analysis of the factors outlined above will, in all probability, be insurable now and in the future. On the other hand, a facility which cannot demonstrate a high level of concern for protection of the environment, attention to engineering details and sound management may not currently be insurable and will most probably not be in the future (or will be able to purchase coverage only at a cost which will be prohibitive). The enactment of state legislation such as Minnesota Bill H.F. No. 76 will not, in itself, make insurance coverage unavailable to all risks within the state. It may, however, enter into the underwriter's consideration of a specific facility, and may have an effect on the availability or price of coverage for that site.

Of special concern in this matter of insurability is the commercial waste disposal facility. The limitations of liability for persons involved in transporting household refuse (Section 4, Sub. 4 and Section 5, Sub. 3) and for municipalities (Section 26) will help to make environmental impairment coverage available for private parties and governmental agencies involved in disposal of domestic refuse where landfill or incinerator facilities are well designed and well maintained. There will, however, still be a problem in insuring facilities which have been in operation for many years and where current monitoring cannot assure underwriters that no harmful substances are migrating from the site. This should not be affected in a significant manner by the liability provisions of H.F. No. 76, since pollution insurance for these facilities is difficult to obtain even in the absence of a state superfund law.

Hazardous waste disposal, treatment or storage facilities will have even more stringent engineering requirements placed upon them as prerequisites to obtaining pollution insurance than domestic waste disposal sites. The liability of these facilities will be insurable only where the owners/operators can assure underwriters that the operation is well designed, operated in accordance with acceptable engineering practices and maintained in like-new condition. Insurance for these facilities will be relatively expensive, but it would be even in the absence of H.F. No. 76. Underwriters of gradual pollution coverage for these facilities are probably equipped to properly evaluate the risk of claims arising from a release from the site. There may, in the future, be a much more careful review of the hazardous waste facility by the CGL underwriter who provides coverage for sudden and accidental releases than has been attempted in the past, and it may be necessary to provide this coverage on a claims-made rather than an occurrence basis to assure an adequate market for the risk.

For generators of hazardous substances, the passage of H.F. No. 76 will not have as much of an impact on the availability or cost of gradual or sudden and accidental pollution liability insurance as will be experienced by hazardous waste treatment, storage and disposal facilities. This is primarily because of the exclusion of coverage in the gradual pollution policy for the cost of cleanup of third party sites (waste disposal facilities owned by others) and of the cost of cleanup of the insured's own facilities. With these items excluded, the risks which are being transferred to the underwriter are much easier to deal with and much more like those which already exist at comon law than is the case with a facility which is in the business of treating, storing or disposing of hazardous wastes.

D. CONCLUSION

All of this theoretical analysis of what may occur if a certain piece of legislation is enacted is of interest to public officials who are considering how to encourage sound management of operations which use hazardous substances and to businessmen who must live with the rules which are created to respond to the public's desire for a safe and pleasant environment. No worthwhile objective such as those sought by S.F. No. 76 can be accomplished wihtout a cost - ultimately borne, not by the state or business, but by the consumers of the products of our industrial enterprises. Insurance cannot provide a complete assurance that citizens of a state will be protected against the consequences of releases of harmful substances into the environment or that the companies who are responsible for a release will be able to pay for all of the damages which may result from their operations. The cost of such assurances can only be guarenteed by the public itself, when that public places a higher value on a clean environment than on other amenities which compete for the limited resources available.

Insurance for environmental liability can, at best, only attempt to redistribute the costs associated with releases of hazardous substances among those who are subject to the risk of such release in a way which allows any one or more of these entities to absorb the cost of a loss without suffering ruinous financial consequences. Collectively, all such companies which have a hazardous materials exposure will spend more to transfer this risk to insurers than they would to pay the costs as they are incurred, but the sharing mechanism will allow the substitution of a known current cost for uncertain future liability. This, like all other insurable risks, will be of interest to underwriters only if they can take in more in premiums than they pay out in losses and expenses.

ENVIRONMENTAL RESPONSE FUND

CHAPTER 121

H.F.No. 76

An Act relating to the environment; establishing an environmental response, compensation and compliance fund to pay for removal and remedial action associated with certain hazardous substances

Underscoring and strikeouts are as shown in enrolled act

released into the environment and for other purposes; providing for liability for cleanup costs, personal injury, economic loss, and damage to natural resources resulting from releases of hazardous substances; providing for studies; imposing taxes, fees, and penalties; providing for injunctive relief; appropriating money; amending Minnesota Statutes 1982, sections 115A.24, subdivision 1; 466.01, by adding a subdivision; and 466.04, subdivision 1; proposing new law coded in Minnesota Statutes, chapter 116; proposing new law coded as Minnesota Statutes, chapter 115B; repealing Minnesota Statutes 1982, section 115A.24, subdivision 2.

Be it enacted by the Legislature of the State of Minnesota:

Section 1.

115B.01. Citation

Sections 115B.01 to 115B.24 may be cited as the Environmental Response and Liability Act.

Sec. 2.

115B.02. Definitions

Subdivision 1. **Application.** For the purposes of sections 115B.01 to 115B.20, the following terms have the meanings given them.

Subd. 2. **Act of God.** "Act of God" means an unanticipated grave natural disaster or other natural phenomenon of an exceptional, inevitable, and irresistible character, the effects of which could not have been prevented or avoided by the exercise of due care or foresight.

Subd. 3. **Agency.** "Agency" means the pollution control agency.

Subd. 4. **Director.** "Director" means the director of the pollution control agency.

Subd. 5. **Facility.** "Facility" means:

(a) Any building, structure, installation, equipment, pipe or pipeline (including any pipe into a sewer or publicly owned treatment works), well, pit, pond, lagoon, impoundment, ditch, landfill, storage container, motor vehicle, rolling stock, or aircraft;

(b) Any watercraft of any description, or other artificial contrivance used or capable of being used as a means of transportation on water; or

(c) Any site or area where a hazardous substance, or a pollutant or contaminant, has been deposited, stored, disposed of, or placed, or otherwise come to be located.

"Facility" does not include any consumer product in consumer use.

Subd. 6. **Federal superfund act.** "Federal Superfund Act" means the Comprehensive Environmental Response, Compensation and Liability Act of 1980, 42 U.S.C. Section 9601 et seq.

Subd. 7. **Fund.** "Fund" means the environmental response, compensation and compliance fund established under section 20.

Subd. 8. Hazardous substance. "Hazardous substance" means:

(a) Any commercial chemical designated pursuant to the Federal Water Pollution Control Act, under 33 U.S.C. Section 1321(b)(2)(A);

(b) Any hazardous air pollutant listed pursuant to the Clean Air Act, under 42 U.S.C. Section 7412; and

(c) Any hazardous waste.

"Hazardous substance" does not include natural gas, natural gas liquids, liquefied natural gas, synthetic gas usable for fuel, or mixtures of such synthetic gas and natural gas, nor does it include petroleum, including crude oil or any fraction thereof which is not otherwise a hazardous waste.

Subd. 9. Hazardous waste. "Hazardous waste" means:

(a) Any hazardous waste as defined in section 116.06, subdivision 13, and any substance identified as a hazardous waste pursuant to rules adopted by the agency under section 116.07; and

(b) Any hazardous waste as defined in the Resource Conservation and Recovery Act, under 42 U.S.C. Section 6903, which is listed or has the characteristics identified under 42 U.S.C. Section 6921, not including any hazardous waste the regulation of which has been suspended by act of Congress.

Subd. 10. Natural resources. "Natural resources" has the meaning given it in section 116B.02, subdivision 4.

Subd. 11. Owner of real property. "Owner of real property" means a person who is in possession of, has the right of control, or controls the use of real property, including without limitation a person who may be a fee owner, lessee, renter, tenant, lessor, contract for deed vendee, licensor, licensee, or occupant; provided that:

(1) A lessor of real property under a lease which in substance is a financing device and is treated as such under the United States Internal Revenue Code, common law, or statute, is not an owner of the real property;

(2) A public utility holding a public utility easement is an owner of the real property described in the easement only for the purpose of carrying out the specific use for which the easement was granted; and

(3) Any person holding a remainder or other nonpossessory interest or estate in real property is an owner of the real property beginning when that person's interest or estate in the real property vests in possession or that person obtains the unconditioned right to possession, or to control the use of, the real property.

Subd. 12. Person. "Person" means any individual, partnership, association, public or private corporation or other entity including the United States government, any interstate body, the state and any agency, department or political subdivision of the state.

Subd. 13. **Pollutant or contaminant.** "Pollutant or contaminant" means any element, substance, compound, mixture, or agent, other than a hazardous substance, which after release from a facility and upon exposure of, ingestion, inhalation, or assimilation into any organism, either directly from the environment or indirectly by ingestion through food chains, will or may reasonably be anticipated to cause death, disease, behavioral abnormalities, cancer, genetic mutation, physiological malfunctions (including malfunctions in reproduction) or physical deformations, in the organisms or their offspring.

"Pollutant or contaminant" does not include natural gas, natural gas liquids, liquefied natural gas, synthetic gas usable for fuel, or mixtures of such synthetic gas and natural gas.

Subd. 14. **Public utility easement.** "Public utility easement" means an easement used for the purposes of transmission, distribution, or furnishing, at wholesale or retail, natural or manufactured gas, or electric or telephone service, by a public utility as defined in section 216B.02, subdivision 4, a cooperative electric association organized under the provisions of chapter 308, a telephone company as defined in section 237.01, subdivisions 2 and 8, or a municipality producing or furnishing gas, electric, or telephone service.

Subd. 15. **Release.** "Release" means any spilling, leaking, pumping, pouring, emitting, emptying, discharging, injecting, escaping, leaching, dumping, or disposing into the environment which occurred at a point in time or which continues to occur.

"Release" does not include:

(a) Emissions from the engine exhaust of a motor vehicle, rolling stock, aircraft, watercraft, or pipeline pumping station engine;

(b) Release of source, byproduct, or special nuclear material from a nuclear incident, as those terms are defined in the Atomic Energy Act of 1954, under 42 U.S.C. Section 2014, if the release is subject to requirements with respect to financial protection established by the federal nuclear regulatory commission under 42 U.S.C. Section 2210;

(c) Release of source, byproduct or special nuclear material from any processing site designated pursuant to the Uranium Mill Tailings Radiation Control Act of 1978, under 42 U.S.C. Section 7912(a)(1) or 7942(a); or

(d) Any release resulting from the application of fertilizer or agricultural or silvicultural chemicals, or disposal of emptied pesticide containers or residues from a pesticide as defined in section 18A.21, subdivision 25.

Subd. 16. **Remedy or remedial action.** "Remedy" or "remedial action" means those actions consistent with permanent remedy taken instead of or in addition to removal actions in the event of a release or threatened release of a hazardous substance, or a pollutant or contaminant, into the environment, to prevent, minimize or eliminate the release in order to protect the public health or welfare or the environment.

"Remedy" or "remedial action" includes, but is not limited to:

(a) Actions at the location of the release such as storage, confinement, perimeter protection using dikes, trenches, or ditches, clay cover, neutralization, cleanup of released hazardous substances, pollutants or contaminants, or contaminated materials, recycling or reuse, diversion, destruction, segregation of reactive wastes, dredging or excavations, repair or replacement of leaking containers, collection of leachate and runoff, onsite treatment or incineration, provision of alternative water supplies, and any monitoring and maintenance reasonably required to assure that these actions protect the public health and welfare and the environment; and

(b) The costs of permanent relocation of residents and businesses and community facilities when the agency determines that, alone or in combination with other measures, relocation is more cost effective than and environmentally preferable to the transportation, storage, treatment, destruction, or secure disposition offsite of hazardous substances, or pollutants or contaminants, or may otherwise be necessary to protect the public health or welfare.

"Remedy" or "remedial action" does not include offsite transport of hazardous substances, pollutants or contaminants, or contaminated materials or their storage, treatment, destruction, or secure disposition offsite unless the agency determines that these actions:

(1) Are more cost effective than other remedial actions;

(2) Will create new capacity to manage hazardous substances in addition to those located at the affected facility, in compliance with section 116.07 and subtitle C of the Solid Waste Disposal Act, 42 U.S.C. Section 6921 et seq.; or

(3) Are necessary to protect the public health or welfare or the environment from a present or potential risk which may be created by further exposure to the continued presence of the hazardous substances, pollutants or contaminants, or contaminated materials.

Subd. 17. Remove or removal. "Remove" or "removal" means:

(a) The cleanup or removal of a released hazardous substance, or a pollutant or contaminant, from the environment;

(b) Necessary actions taken in the event of a threatened release of a hazardous substance, or a pollutant or contaminant, into the environment;

(c) Actions necessary to monitor, test, analyze, and evaluate a release or threatened release of a hazardous substance, or a pollutant or contaminant;

(d) Disposal or processing of removed material; or

(e) Other actions necessary to prevent, minimize, or mitigate damage to the public health or welfare or the environment, which may otherwise result from a release or threatened release.

"Remove" or "removal" includes, but is not limited to, security fencing or other measures to limit access, provision of alternative water supplies, temporary evacuation and housing of threatened individuals not otherwise provided for, action taken pursuant to the Federal Superfund Act, under 42

U.S.C. Section 9604(b), and any emergency assistance which may be provided under the Disaster Relief Act of 1974, 42 U.S.C. Section 5121 et seq.

Subd. 18. Respond or response. "Respond" or "response" means remove, removal, remedy, and remedial action.

Subd. 19. Water. "Water" has the meaning given to the term "waters of the state" in section 115.01, subdivision 9.

Sec. 3.

115B.03. Responsible person

Subdivision 1. General rule. For the purposes of sections 115B.01 to 115B.20, and except as provided in subdivisions 2 and 3, a person is responsible for a release or threatened release of a hazardous substance, or a pollutant or contaminant, from a facility if the person:

(a) Owned or operated the facility: (1) when the hazardous substance, or pollutant or contaminant, was placed or came to be located in or on the facility; (2) when the hazardous substance, or pollutant or contaminant, was located in or on the facility but before the release; or (3) during the time of the release or threatened release;

(b) Owned or possessed the hazardous substance, or pollutant or contaminant, and arranged, by contract, agreement or otherwise, for the disposal, treatment or transport for disposal or treatment of the hazardous substance, or pollutant or contaminant; or

(c) Knew or reasonably should have known that waste be accepted for transport to a disposal or treatment facility contained a hazardous substance, or pollutant or contaminant, and either selected the facility to which it was transported or disposed of it in a manner contrary to law.

Subd. 2. Employees and employers. When a person who is responsible for a release or threatened release as provided in subdivision 1 is an employee who is acting in the scope of his employment:

(a) The employee is subject to liability under section 115B.04 or 115B.05 only if his conduct with respect to the hazardous substance was negligent under circumstances in which he knew that the substance was hazardous and that his conduct, if negligent, could result in serious harm.

(b) His employer shall be considered a person responsible for the release or threatened release and is subject to liability under section 115B.04 or 115B.05 regardless of the degree of care exercised by the employee.

Subd. 3. Owner of real property. An owner of real property is not a person responsible for the release or threatened release of a hazardous substance from a facility in or on the property unless that person:

(a) was engaged in the business of generating, transporting, storing, treating, or disposing of a hazardous substance at the facility or disposing of waste at the facility, or knowingly permitted others to engage in such a business at the facility;

(b) knowingly permitted any person to make regular use of the facility for disposal of waste;

(c) knowingly permitted any person to use the facility for disposal of a hazardous substance;

(d) knew or reasonably should have known that a hazardous substance was located in or on the facility at the time right, title, or interest in the property was first acquired by the person and engaged in conduct by which he associated himself with the release; or

(e) took action which significantly contributed to the release after he knew or reasonably should have known that a hazardous substance was located in or on the facility.

For the purpose of clause (d), a written warranty, representation, or undertaking, which is set forth in an instrument conveying any right, title or interest in the real property and which is executed by the person conveying the right, title or interest, or which is set forth in any memorandum of any such instrument executed for the purpose of recording, is admissible as evidence of whether the person acquiring any right, title, or interest in the real property knew or reasonably should have known that a hazardous substance was located in or on the facility.

Any liability which accrues to an owner of real property under sections 115B.01 to 115B.15 does not accrue to any other person who is not an owner of the real property merely because the other person holds some right, title, or interest in the real property.

An owner of real property on which a public utility easement is located is not a responsible person with respect to any release caused by any act or omission of the public utility which holds the easement in carrying out the specific use for which the easement was granted.

Sec. 4.

115B.04. Liability for response costs and natural resources; limitations and defenses

Subdivision 1. **Liability.** Except as otherwise provided in subdivisions 2 to 12, and notwithstanding any other provision or rule of law, any person who is responsible for a release or threatened release of a hazardous substance from a facility is strictly liable, jointly and severally, for the following response costs and damages which result from the release or threatened release or to which the release or threatened release significantly contributes:

(a) All reasonable and necessary response costs incurred by the state, a political subdivision of the state or the United States;

(b) All reasonable and necessary removal costs incurred by any person; and

(c) All damages for any injury to, destruction of, or loss of natural resources, including the reasonable costs of assessing such injury, destruction, or loss.

Subd. 2. **Liability for pollutant or contaminant excluded.** There is no liability under this section for response costs or damages which result from the release of a pollutant or contaminant.

Subd. 3. **Liability for a threatened release.** Liability under this section for a threatened release of a hazardous substance is limited to the recovery by the agency of reasonable and necessary response costs as provided in section 115B.17, subdivision 6.

Subd. 4. **Liability of political subdivisions.** The liability of a political subdivision under this section is subject to the limits imposed under section 466.04, subdivision 1.

Subd. 5. **Transportation of household refuse.** A person who accepts only household refuse for transport to a treatment or disposal facility is not liable under this section for the release or threatened release of any hazardous substance unless he knew or reasonably should have known that the hazardous substance was present in the refuse. For the purpose of this subdivision, household refuse means garbage, trash, or septic tank sanitary wastes generated by single or multiple residences, hotels, motels, restaurants and other similar facilities.

Subd. 6. **Defense to certain claims by political subdivisions and private persons.** It is a defense to a claim by a political subdivision or private person for recovery of the costs of its response actions under this section that the hazardous substance released from the facility was placed or came to be located in or on the facility before April 1, 1982, and that the response actions of the political subdivision or private person were not authorized by the agency as provided in section 115B.17, subdivision 12. This defense applies only to response costs incurred on or after July 1, 1983.

Subd. 7. **Defense for intervening acts.** It is a defense to liability under this section that the release or threatened release was caused solely by:

(a) An act of God;

(b) An act of war;

(c) An act of vandalism or sabotage; or

(d) An act or omission of a third party or the plaintiff.

"Third party" for the purposes of clause (d) does not include an employee or agent of the defendant, or a person in the chain of responsibility for the generation, transportation, storage, treatment, or disposal of the hazardous substance.

The defenses provided in clauses (c) and (d) apply only if the defendant establishes that he exercised due care with respect to the hazardous substance concerned, taking into consideration the characteristics of the hazardous substance in light of all relevant facts and circumstances which he knew or should have known, and that he took precautions against foreseeable acts or omissions and the consequences that could foreseeably result from those acts or omissions.

Subd. 8. **Intervening acts of public agencies.** When the agency or the federal environmental protection agency assumes control over any release or threatened release of a hazardous substance by taking removal actions at the site of the release, the persons responsible for the release are not liable under sections 115B.01 to 115B.15 for any subsequent release of the hazardous substance from another facility to which it has been removed.

Subd. 9. **Releases subject to certain permits or standards; federal post-closure fund.** It is a defense to liability under this section that:

(a) The release or threatened release was from a hazardous waste facility as defined under section 115A.03, for which a permit had been issued pursuant to section 116.07 or pursuant to subtitle C of the Solid Waste Disposal Act, 42 U.S.C. Section 6921 et seq., the hazardous substance was specifically identified in the permit, and the release was within the limits allowed in the permit for release of that substance;

(b) The hazardous substance released was specifically identified in a federal or state permit and the release is within the limits allowed in the permit;

(c) The release resulted from circumstances identified and reviewed and made a part of the public record of a federal or state agency with respect to a permit issued or modified under federal or state law, and the release conformed with the permit;

(d) The release was any part of an emission or discharge into the air or water and the emission or discharge was subject to a federal or state permit and was in compliance with control rules or regulations adopted pursuant to state or federal law;

(e) The release was the introduction of any hazardous substance into a publicly owned treatment works and the substance was specified in, and is in compliance with, applicable pretreatment standards specified for that substance under state and federal law; or

(f) Liability has been assumed by the federal post-closure liability fund under 42 U.S.C. Section 9607(k).

Subd. 10. **Natural resources.** It is a defense to liability under this section, for any injury to, destruction of, or loss of natural resources that:

(a) The natural resources were specifically identified as an irreversible and irretrievable commitment of natural resources in an approved final state or federal environmental impact statement, or other comparable approved final environmental analysis for a project or facility which was the subject of a governmental permit or license; and

(b) The project or facility was being operated within the terms of its permit or license.

Subd. 11. **Rendering assistance in response actions.** It is a defense to liability under this section that the response costs or damages resulted from acts taken or omitted in preparation for, or in the course of rendering care, assistance, or advice to the director or agency pursuant to section 115B.17 or in accordance with the national hazardous substance response plan pursuant to the Federal Superfund Act, under 42 U.S.C. Section 9605, or at the direction of an on-scene coordinator appointed under that plan, with respect to any release or threatened release of a hazardous substance.

Subd. 12. **Burden of proof for defenses.** Any person claiming a defense provided in subdivisions 6 to 11 has the burden to prove all elements of the defense by a preponderance of the evidence.

Sec. 5.

115B.05. Liability for economic loss, death, personal injury and disease; limitations and defenses

Subdivision 1. **Liability.** Except as otherwise provided in subdivisions 2 to 10, and notwithstanding any other provision or rule of law, any person who is responsible for the release of a hazardous substance from a facility is strictly liable, jointly and severally, for the following damages which result from the release or to which the release significantly contributes:

(a) All damages for actual economic loss including:

(1) Any injury to, destruction of, or loss of any real or personal property, including relocation costs;

(2) Any loss of use of real or personal property;

(3) Any loss of past or future income or profits resulting from injury to, destruction of, or loss of real or personal property without regard to the ownership of the property; and

(b) All damages for death, personal injury, or disease including:

(1) Any medical expenses, rehabilitation costs or burial expenses;

(2) Any loss of past or future income, or loss of earning capacity; and

(3) Damages for pain and suffering, including physical impairment.

Subd. 2. **Liability for pollutant or contaminant excluded.** There is no liability under this section for damages which result from the release of a pollutant or contaminant.

Subd. 3. **Certain employee claims not covered.** Except for a third party who is subject to liability under section 176.061, subdivision 5, there is no liability under this section for the death, personal injury or disease of an employee which is compensable under chapter 176 as an injury or disease arising out of and in the course of employment.

Subd. 4. **Liability limitations.** The liability of a political subdivision under this section is subject to the limits imposed under section 466.04, subdivision 1.

Subd. 5. **Transportation of household refuse.** A person who accepts only household refuse for transport to a treatment or disposal facility is not liable under this section for the release or threatened release of any hazardous substance unless he knew or reasonably should have known that the hazardous substance was present in the refuse. For the purpose of this subdivision, household refuse means garbage, trash, or septic tank sanitary wastes generated by single or multiple residences, hotels, motels, restaurants and other similar facilities.

Subd. 6. **Defense for intervening acts.** It is a defense to liability under this section that the release or threatened release was caused solely by:

(a) An act of God;

(b) An act of war;

(c) An act of vandalism or sabotage; or

(d) An act or omission of a third party or the plaintiff.

"Third party" for the purposes of clause (d) does not include an employee or agent of the defendant, or a person in the chain of responsibility for the generation, transportation, storage, treatment, or disposal of the hazardous substance.

The defenses provided in clauses (c) and (d) apply only if the defendant establishes that he exercised due care with respect to the hazardous substance concerned, taking into consideration the characteristics of the hazardous substance in light of all relevant facts and circumstances which he knew or should have known, and that he took precautions against foreseeable acts or omissions and the consequences that could foreseeably result from those acts or omissions.

Subd. 7. **Intervening acts of public agencies.** When the agency or the federal environmental protection agency assumes control over any release or threatened release of a hazardous substance by taking removal actions at the site of the release, the persons responsible for the release are not liable under sections 115B.01 to 115B.15 for any subsequent release of the hazardous substance from another facility to which it has been removed.

Subd. 8. **Releases subject to certain permits or standards; federal post-closure fund.** It is a defense to liability under this section that:

(a) The release or threatened release was from a hazardous waste facility as defined under section 115A.03, for which a permit had been issued pursuant to section 116.07 or pursuant to subtitle C of the Solid Waste Disposal Act, 42 U.S.C. Section 6921 et seq., the hazardous substance was specifically identified in the permit, and the release was within the limits allowed in the permit for release of that substance;

(b) The hazardous substance released was specifically identified in a federal or state permit and the release is within the limits allowed in the permit;

(c) The release resulted from circumstances identified and reviewed and made a part of the public record of a federal or state agency with respect to a permit issued or modified under federal or state law, and the release conformed with the permit;

(d) The release was any part of an emission or discharge into the air or water and the emission or discharge was subject to a federal or state permit and was in compliance with control rules or regulations adopted pursuant to state or federal law;

(e) The release was the introduction of any hazardous substance into a publicly owned treatment works and the substance was specified in, and is in compliance with, applicable pretreatment standards specified for that substance under state and federal law; or

(f) Liability has been assumed by the federal post-closure liability fund under 42 U.S.C. Section 9607(k).

Subd. 9. Rendering assistance in response actions. It is a defense to liability under this section that the damages resulted from acts taken or omitted in preparation for, or in the course of rendering care, assistance, or advice to the director or agency pursuant to section 115B.17 or in accordance with the national hazardous substance response plan pursuant to the Federal Superfund Act, under 42 U.S.C. Section 9605, or at the direction of an on-scene coordinator appointed under that plan, with respect to any release or threatened release of a hazardous substance.

Subd. 10. Burden of proof for defenses. Any person claiming a defense provided in subdivisions 6 to 9 has the burden to prove all elements of the defense by a preponderance of the evidence.

Sec. 6.

115B.06. Application to past actions

Subdivision 1. Application of section 115B.05 and additional defense. (a) A defendant in an action under section 115B.05 has the additional defense provided in subdivision 2 for damages caused or significantly contributed to by the release of a hazardous substance from a facility if the defendant shows that the substance was placed or came to be located in or on the facility wholly before January 1, 1973.

(b) Section 115B.05 does not apply to any claim for damages arising out of the release of a hazardous substance which was placed or came to be located in or on the facility wholly before January 1, 1960.

Subd. 2. Additional defense. For a defendant who has made the showing required in subdivision 1, clause (a), it is a defense to liability under section 115B.05 that the activity by which the substance was kept, placed, or came to be located in or on the facility was not an abnormally dangerous activity. The determination of whether the activity was an abnormally dangerous activity shall be made by the court.

Sec. 7.

115B.07. Causation

In any action brought under section 115B.05 or any other law to recover damages for death, personal injury, or disease arising out of the release of a hazardous substance, the court may not direct a verdict against the plaintiff on the issue of causation if the plaintiff produces evidence sufficient to enable a reasonable person to find that:

(a) the defendant is a person who is responsible for the release;

(b) the plaintiff was exposed to the hazardous substance;

(c) the release could reasonably have resulted in plaintiff's exposure to the substance in the amount and duration experienced by the plaintiff; and

(d) the death, injury, or disease suffered by the plaintiff is caused or significantly contributed to by exposure to the hazardous substance in an amount and duration experienced by the plaintiff.

Evidence to a reasonable medical certainty that exposure to the hazardous substance caused or significantly contributed to the death, injury, or disease is not required for the question of causation to be submitted to the trier of fact.

Nothing in this section shall be construed to relieve the plaintiff of the burden of proving that the defendant is a person who is responsible for the release and of proving the causal connection between the release of the hazardous substance for which the defendant is a responsible person and the plaintiff's death, injury, or disease.

Sec. 8.

115B.08. Liability under section 115B.04; apportionment and contribution

Subdivision 1. Right of apportionment; factors. Any person held jointly and severally liable under section 115B.04 has the right at trial to have the trier of fact apportion liability among the parties as provided in this section. The burden is on each defendant to show how his liability should be apportioned. The court shall reduce the amount of damages in proportion to any amount of liability apportioned to the party recovering.

In apportioning the liability of any party under this section, the trier of fact shall consider the following:

(a) The extent to which that party's contribution to the release of a hazardous substance can be distinguished;

(b) The amount of hazardous substance involved;

(c) The degree of toxicity of the hazardous substance involved;

(d) The degree of involvement of and care exercised by the party in manufacturing, treating, transporting, and disposing of the hazardous substance;

(e) The degree of cooperation by the party with federal, state, or local officials to prevent any harm to the public health or the environment; and

(f) Knowledge by the party of the hazardous nature of the substance.

Subd. 2. Contribution. If a person is held jointly and severally liable under section 115B.04 and establishes his proportionate share of the aggregate liability, the provisions of section 604.02, subdivisions 1 and 2, shall apply with respect to contribution and reallocation of any uncollectible amounts.

Sec. 9.

115B.09. Liability under section 115B.05; comparative fault and contribution

The provisions of sections 604.01, 604.02, subdivisions 1 and 2, apply to any action for damages under section 115B.05, except that, if the percentage of fault attributable to a defendant is determined under section 604.01, the liability of the defendant shall be limited to two times that percentage of the damages recoverable in the action.

Sec. 10.

115B.10. No avoidance of liability; insurance and subrogation

An owner or operator of a facility or any other person who may be liable under sections 115B.01 to 115B.15 may not avoid that liability by means of any conveyance of any right, title, or interest in real property, or by any indemnification, hold harmless agreement, or similar agreement. Nothing in this section shall be construed:

(a) To prohibit any party who may be liable under sections 115B.01 to 115B.15 from entering an agreement by which that party is insured, held harmless or indemnified for part or all of that liability;

(b) To prohibit the enforcement of any insurance, hold harmless or indemnification agreement; or

(c) To bar any cause of action brought by a party who may be liable under sections 115B.01 to 115B.15 or by an insurer or guarantor, whether by right of subrogation or otherwise.

Sec. 11.

115B.11. Statute of limitations

No person may recover pursuant to sections 115B.01 to 115B.15 unless the action is commenced within six years from the date when the cause of action accrues. In determining when the cause of action accrues for an action to recover damages for death, personal injury or disease, the court shall consider factors including the following:

(a) When the plaintiff discovered the injury or loss;

(b) Whether a personal injury or disease had sufficiently manifested itself; and

(c) When the plaintiff discovered, or using due diligence should have discovered, a causal connection between the injury, disease, or loss and the release of a hazardous substance.

Sec. 12.

115B.12. Other remedies preserved

Nothing in sections 115B.01 to 115B.15 shall be construed to abolish or diminish any remedy or affect the right of any person to bring a legal action or use any remedy available under any other provision of state or federal law, including common law, to recover for personal injury, disease, economic loss or response costs arising out of a release of any hazardous substance, or for removal or the costs of removal of that hazardous substance. Nothing in sections 115B.01 to 115B.15 shall be construed to limit or restrict in any way the liability of any person under any other state or federal law, including common law, for loss due to personal injury or disease, for economic loss, or for response costs arising out of any release or threatened release of a hazardous substance from a facility regardless of the time at which a hazardous substance was placed or came to be located in or on the facility. The provisions of sections 115B.01 to 115B.15 shall not be considered, interpreted, or construed in any way as reflecting a determination, in whole or in part, of policy regarding the inapplicability of strict liability, or strict liability doctrines under any other state or federal law, including common law, to activities past, present or future, relating to hazardous substances, or pollutants or contaminants, or other similar activities.

Sec. 13.

115B.13. Double recovery prohibited

A person who recovers response costs or damages pursuant to sections 115B.01 to 115B.15 may not recover the same costs or damages pursuant to any other law. A person who recovers response costs or damages pursuant to any other state or federal law may not recover for the same costs or damages pursuant to sections 115B.01 to 115B.15.

Sec. 14.

115B.14. Award of costs

Upon motion of a party prevailing in an action under sections 115B.01 to 115B.15 the court may award costs, disbursements and reasonable attorney fees and witness fees to that party.

Sec. 15.

115B.15. Application of sections 115B.01 to 115B.14

Sections 115B.01 to 115B.14 apply to any release or threatened release of a hazardous substance occurring on or after July 1, 1983, including any release which began before July 1, 1983, and continued after that date. Sections 115B.01 to 115B.14 do not apply to a release or threatened release which occurred wholly before July 1, 1983, regardless of the date of discovery of any injury or loss caused by the release or threatened release.

Sec. 16.

115B.16. Disposition of facilities

Subdivision 1. **Closed disposal facilities; use of property.** No person shall use any property on or in which hazardous waste remains after closure of a disposal facility as defined in section 115A.03, subdivision 10, in any way that disturbs the integrity of the final cover, liners, or any other components of any containment system, or the function of the disposal facility's monitoring systems, unless the agency finds that the disturbance:

(a) Is necessary to the proposed use of the property, and will not increase the potential hazard to human health or the environment; or

(b) Is necessary to reduce a threat to human health or the environment.

Subd. 2. **Recording of affidavit.** Before any transfer of ownership of any property which the owner knew or should have known was used as the site of a hazardous waste disposal facility as defined in section 115A.03, subdivision 10, or which the owner knew or should have known is subject to extensive contamination by release of a hazardous substance, the owner shall record with the county recorder of the county in which the property is located an affidavit containing a legal description of the property that discloses to any potential transferee:

(a) That the land has been used to dispose of hazardous waste or that the land is contaminated by a release of a hazardous substance;

(b) The identity, quantity, location, condition and circumstances of the disposal or contamination to the full extent known or reasonably ascertainable; and

(c) That the use of the property or some portion of it may be restricted as provided in subdivision 1.

An owner must also file an affidavit within 60 days after any material change in any matter required to be disclosed under clauses (a) to (c) with respect to property for which an affidavit has already been recorded.

If the owner or any subsequent owner of the property removes the hazardous substance, together with any residues, liner, and contaminated underlying and surrounding soil, that owner may record an affidavit indicating the removal of the hazardous substance.

Failure to record an affidavit as provided in this subdivision does not affect or prevent any transfer of ownership of the property.

Subd. 3. Duty of county recorder. The county recorder shall record all affidavits presented to him in accordance with subdivision 2. The affidavits shall be recorded in a manner which will assure their disclosure in the ordinary course of a title search of the subject property.

Subd. 4. Penalties. (a) Any person who knowingly violates the provisions of subdivision 1 is subject to a civil penalty in an amount determined by the court of not more than $100,000, and shall be liable under sections 115B.04 and 115B.05 for any release or threatened release of any hazardous substance resulting from the violation.

(b) Any person who knowingly fails to record an affidavit as required by subdivision 2 shall be liable under sections 115B.04 and 115B.05 for any release or threatened release of any hazardous substance from a facility located on that property.

(c) A civil penalty may be imposed and recovered by an action brought by a county attorney or by the attorney general in the district court of the county in which the property is located.

(d) Any civil fines recovered under this subdivision shall be deposited in the fund.

Sec. 17.

115B.17. State response to releases

Subdivision 1. Removal and remedial action. Whenever there is a release or substantial threat of release from a facility of any pollutant or contaminant which presents an imminent and substantial danger to the public health or welfare or the environment or whenever a hazardous substance is released or there is a threatened release of a hazardous substance from a facility:

(a) The agency may take any removal or remedial action relating to the hazardous substance, or pollutant or contaminant, which the agency deems necessary to protect the public health or welfare or the environment. Before taking any action the agency shall:

(1) Request any responsible party known to the agency to take actions which the agency deems reasonable and necessary to protect the public health or welfare or the environment, stating the reasons for the actions, a reasonable time for beginning and completing the actions taking into account the urgency of the actions for protecting the public health or welfare or the environment, and the intention of the agency to take action if the requested actions are not taken as requested;

(2) Notify the owner of real property where the facility is located or where response actions are proposed to be taken, if the owner is not a responsible party, that responsible parties have been requested to take response actions and that the owner's cooperation will be required in order for responsible parties or the agency to take those actions; and

(3) Determine that the actions requested by the agency will not be taken by any known responsible party in the manner and within the time requested.

(b) The director may take removal action which he deems necessary to protect the public health or welfare or the environment if the director determines that the release or threatened release constitutes an emergency requiring immediate action to prevent, minimize or mitigate damage to the public health or welfare or the environment. Before taking any action the director shall make reasonable efforts in light of the urgency of the action to follow the procedure provided in clause (a).

No removal action taken by any person shall be construed as an admission of liability for a release or threatened release.

Subd. 2. Other actions. Whenever the agency or director is authorized to act pursuant to subdivision 1 or whenever the agency or director has reason to believe that a release of a hazardous substance, or a pollutant or contaminant, has occurred or is about to occur, or that illness, disease, or complaints thereof may be attributable to exposure to a hazardous substance, or a pollutant or contaminant, the agency or director may undertake investigations, monitoring, surveys, testing, and other similar activities necessary or appropriate to identify the existence and extent of the release or threat thereof, the source and nature of the hazardous substances, or pollutants or contaminants, and the extent of danger to the public health or welfare or the environment. In addition, the agency may undertake planning, legal, fiscal, economic, engineering, architectural, and other studies or investigations necessary or appropriate to plan and direct a response action, to recover the costs of the response action, and to enforce the provisions of sections 115B.01 to 115B.18.

Subd. 3. Duty to provide information. Any person who the agency has reason to believe is responsible for a release or threatened release as provided in section 115B.03, or who is the owner of real property where the release or threatened release is located or where response actions are proposed to be taken, when requested by the agency, or any member, employee or agent thereof who is authorized by the agency, shall furnish to the agency any information which he may have or may reasonably obtain which is relevant to the release or threatened release.

Subd. 4. Access to information and property. The agency or any member, employee or agent thereof authorized by the agency, upon presentation of credentials, may:

(a) Examine and copy any books, papers, records, memoranda or data of any person who has a duty to provide information to the agency under subdivision 3; and

(b) Enter upon any property, public or private, for the purpose of taking any action authorized by this section including obtaining information from any person who has a duty to provide the information under subdivision 3, conducting surveys or investigations, and taking removal or remedial action.

Subd. 5. Classification of data. Except as otherwise provided in this subdivision, data obtained from any person pursuant to subdivision 3 or 4 is public data as defined in section 13.02. Upon certification by the subject of the data that the data relates to sales figures, processes or methods of production unique to that person, or information which would tend to affect adversely the competitive position of that person, the director shall classify the data as private or nonpublic data as defined in section 13.02. Notwithstanding any other law to the contrary, data classified as private or nonpublic under this subdivision may be disclosed when relevant in any proceeding under sections 115B.01 to 115B.18, or to other public agencies concerned with the implementation of sections 115B.01 to 115B.18.

Subd. 6. Recovery of expenses. Any reasonable and necessary expenses incurred by the agency or director pursuant to this section, including all response costs, and administrative and legal expenses, may be recovered in a civil action brought by the attorney general against any person who may be liable under section 115B.04 or any other law. The agency's certification of expenses shall be prima facie evidence that the expenses are reasonable and necessary. Any expenses incurred pursuant to this section which are recovered by the attorney general pursuant to section 115B.04 or any other law, including any award of attorneys fees, shall be deposited in the fund and credited to a special account for additional response actions as provided in section 115B.20, subdivision 2, clause (b) or (d).

Subd. 7. Actions relating to natural resources. For the purpose of this subdivision, the state is the trustee of the air, water and wildlife of the state. An action pursuant to section 115B.04 for damages with respect to air, water or wildlife may be brought by the attorney general in the name of the state as trustee for those natural resources. Any damages recovered by the attorney general pursuant to section 115B.04 or any other law for injury to, destruction of, or loss of natural resources resulting from the release of a hazardous substance, or a pollutant or contaminant, shall be deposited in the fund and credited to a special account for the purposes provided in section 115B.20, subdivision 2, clause (f).

Subd. 8. Actions relating to pesticides or fertilizer or soil or plant amendments. When the commissioner of agriculture has reported an incident involving the release of pesticides under the provisions of section 18A.37 or the release of fertilizers or soil or plant amendments, and the agency determines that the incident constitutes a release of a hazardous substance, or a pollutant or contaminant, the agency shall authorize the commissioner, subject to the provisions of subdivision 13, to take any action which the agency would be authorized to take under subdivisions 1 to 4. Subject to the provisions of section 115B.20, subdivision 3, the agency shall reimburse the commissioner from the fund for the reasonable and necessary expenses incurred in taking those actions and may recover any amount spent from the fund under subdivision 6.

Subd. 9. Actions relating to occupational safety and health. The agency, director and the commissioner of labor and industry shall make reasonable efforts to coordinate any actions taken under this section and under sections 182.65 to 182.674 to avoid duplication or conflict of actions or requirements with respect to a release or threatened release affecting the safety of any conditions or place of employment.

Subd. 10. Actions relating to health. The agency and director shall make reasonable efforts to coordinate and consult with the commissioner of health in planning and directing response actions with respect to a release or threatened release affecting the public health. If the commissioner of health, upon the request of the agency, takes any actions authorized under this section, the agency shall reimburse the commissioner from the fund for the reasonable and necessary expenses incurred in taking those actions and may recover any amount spent from the fund under subdivision 6.

Subd. 11. Limit on actions by political subdivisions. When the agency or director has requested a person who is responsible for a release or threatened release to take any response action under subdivision 1, no political subdivision shall request or order that person to take any action which conflicts with the action requested by the agency or director.

Subd. 12. Authorization of certain response actions. For the purpose of permitting a political subdivision or private person to recover response costs as provided in section 115B.04, subdivision 6, the agency may authorize the political subdivision to take removal or remedial actions or may authorize the private person to take removal actions with respect to any release of a hazardous substance which was placed or came to be located in the facility before April 1, 1982. The authorization shall be based on application of the criteria in the rules of the agency adopted under subdivision 13 or, if the rules have not been adopted, under the criteria set forth in subdivision 13 on which the rules are required to be based. The authorization shall not be inconsistent with the criteria. This subdivision shall not be construed to prohibit a political subdivision or private person from taking removal or remedial actions without the authorization of the agency.

Subd. 13. Priorities; rules. By November 1, 1983, the agency shall establish a temporary list of priorities among releases or threatened releases for the purpose of taking remedial action and, to the extent practicable consistent with the urgency of the action, for taking removal action under this section. The temporary list, with any necessary modifications, shall remain in effect until the agency adopts rules establishing state criteria for determining priorities among releases and threatened releases. The agency shall adopt the rules by July 1, 1984. After rules are adopted, a permanent priority list shall be established, and may be modified from time to time, according to the criteria set forth in the rules. Before any list is established under this subdivision the agency shall publish the list in the state register and allow 30 days for comments on the list by the public.

The temporary list and the rules required by this subdivision shall be based upon the relative risk or danger to public health or welfare or the environment, taking into account to the extent possible the population at risk, the hazardous potential of the hazardous substances at the facilities, the potential for contamination of drinking water supplies, the potential for direct human contact, the potential for destruction of sensitive ecosystems, the administrative and financial capabilities of the agency, and other appropriate factors.

Sec. 18.

115B.18. Failure to take requested actions; civil penalties; action to compel performance; injunctive relief

Subdivision 1. Civil penalties. Any person responsible for a release or threatened release from a facility of a pollutant or contaminant which presents an imminent and substantial danger to the public health or welfare or the environment or for a release or threatened release of a hazardous substance from a facility shall forfeit and pay to the state a civil penalty in an amount to be determined by the court of not more than $20,000 per day for each day that the person fails to take reasonable and necessary response actions or to make reasonable progress in completing response actions requested as provided in subdivision 3.

The penalty provided under this subdivision may be recovered by an action brought by the attorney general in the name of the state in connection with an action to recover expenses of the agency under section 115B.17, subdivision 6, or by a separate action in the district court of Ramsey County. All penalties recovered under this subdivision shall be deposited in the fund.

Subd. 2. Action to compel performance. When any person who is responsible for a release or threatened release from a facility of a pollutant or contaminant which presents an imminent and substantial danger to the public health or welfare or the environment or for a release or threatened release of a hazardous substance from a facility, fails to take response actions or to make reasonable progress in completing response actions requested as provided in subdivision 3, the attorney general may bring an action in the name of the state to compel performance of the requested response actions. If any person having any right, title, or interest in and to the real property where the facility is located or where response actions are proposed to be taken is not a person responsible for the release or threatened release, the person may be joined as an indispensable party in an action to compel performance in order to assure that the requested response actions can be taken on that property by the responsible parties.

Subd. 3. Requests for response actions. A request for emergency removal action shall be made by the director. Other requests for response actions shall be made by the agency. A request shall be in writing, shall state the action requested, the reasons for the action, and a reasonable time by which the action must be begun and completed taking into account the urgency of the action for protection of the public health or welfare or the environment.

Subd. 4. Injunctive relief. The release or threatened release of a hazardous substance, or a pollutant or contaminant, shall constitute a public nuisance and may be enjoined in an action, in the name of the state, brought by the attorney general.

Sec. 19.

115B.19. Purposes of fund and taxes

In establishing the environmental response, compensation and compliance fund in section 115B.20 and imposing taxes in section 115B.22 it is the purpose of the legislature to:

(a) Encourage treatment and disposal of hazardous waste in a manner that adequately protects the public health or welfare or the environment;

(b) Encourage responsible parties to provide the response actions necessary to protect the public and the environment from the effects of the release of hazardous substances;

(c) Encourage the use of alternatives to land disposal of hazardous waste including resource recovery, recycling, neutralization, and reduction;

(d) Provide state agencies with the financial resources needed to prepare and implement an effective and timely state response to the release of hazardous substances, including investigation, planning, removal and remedial action;

(e) Compensate for increased governmental expenses and loss of revenue and to provide other appropriate assistance to mitigate any adverse impact on communities in which commercial hazardous waste processing or disposal facilities are located under the siting process provided in chapter 115A;

(f) Recognize the environmental and public health costs of land disposal of solid waste and of the use and disposal of hazardous substances and to place the burden of financing state hazardous waste management activities on those whose products and services contribute to hazardous waste management problems and increase the risks of harm to the public and the environment.

Sec. 20.

115B.20. Environmental response, compensation and compliance fund

Subdivision 1. Establishment. The environmental response, compensation and compliance fund is created as an account in the state treasury and may be spent only for the purposes provided in subdivision 2.

Subd. 2. Purposes for which money may be spent. Subject to appropriation by the legislature the money in the fund may be spent for any of the following purposes:

(a) Preparation by the agency for taking removal or remedial action under section 115B.17, including investigation, monitoring and testing activities, enforcement and compliance efforts relating to the release of hazardous substances, pollutants or contaminants under section 115B.17 or 115B.18;

(b) Removal and remedial actions taken or authorized by the agency or director under section 115B.17, including related enforcement and compliance efforts under section 115B.17 or 115B.18, and payment of the state share of the cost of remedial action which may be carried out under a cooperative agreement with the federal government pursuant to the Federal Superfund Act, under 42 U.S.C. Section 9604(c)(3) for actions related to facilities other than commercial hazardous waste facilities located under the siting authority of chapter 115A;

(c) Reimbursement to any private person for expenditures made before July 1, 1983 to provide alternative water supplies deemed necessary by the agency and the department of health to protect the public health from contamination resulting from the release of a hazardous substance;

(d) Removal and remedial actions taken or authorized by the agency or director under section 115B.17 including related enforcement and compliance efforts under section 115B.17 or 115B.18, and payment of the state share of the cost of remedial action which may be carried out under a cooperative agreement with the federal government pursuant to the Federal Superfund Act, under 42 U.S.C. Section 9604(c)(3) for actions related to commercial hazardous waste facilities located under the siting authority of chapter 115A;

(e) Compensation as provided by law, after submission by the waste management board of the report required under section 115A.08, subdivision 5, to mitigate any adverse impact of the location of commercial hazardous waste processing or disposal facilities located pursuant to the siting authority of chapter 115A;

(f) Planning and implementation by the commissioner of natural resources of the rehabilitation, restoration or acquisition of natural resources to remedy injuries or losses to natural resources resulting from the release of a hazardous substance;

(g) Inspection, monitoring and compliance efforts by the agency, or by political subdivisions with agency approval, of commercial hazardous waste facilities located under the siting authority of chapter 115A;

(h) Grants by the agency or the waste management board to demonstrate alternatives to land disposal of hazardous waste including reduction, separation, pretreatment, processing and resource recovery, for education of persons involved in regulating and handling hazardous waste;

(i) Intervention and environmental mediation by the legislative commission on waste management under chapter 115A; and

(j) Grants by the agency to study the extent of contamination and feasibility of cleanup of hazardous substances and pollutants or contaminants in major waterways of the state.

Subd. 3. **Limit on certain expenditures.** The director or agency may not spend any money under subdivision 2, clause (b) or (d) for removal or remedial actions to the extent that the costs of those actions may be compensated from any fund established under the Federal Superfund Act, 42 U.S.C. Section 9600 et seq. The director or agency shall determine the extent to which any of the costs of those actions may be compensated under the federal act based on the likelihood that the compensation will be available in a timely fashion. In making this determination the director or agency shall take into account:

(a) The urgency of the removal or remedial actions and the priority assigned under the Federal Superfund Act to the release which necessitates those actions;

(b) The availability of money in the funds established under the Federal Superfund Act; and

(c) The consistency of any compensation for the cost of the proposed actions under the Federal Superfund Act with the national contingency plan, if such a plan has been adopted under that act.

Subd. 4. **Revenue sources.** Revenue from the following sources shall be deposited in the environmental response, compensation and compliance fund:

(a) The proceeds of the taxes imposed pursuant to section 115B.22, including interest and penalties;

(b) All money recovered by the state under sections 115B.01 to 115B.18 or under any other statute or rule related to the regulation of hazardous waste or hazardous substances, including civil penalties and money paid under any agreement, stipulation or settlement but excluding fees imposed under section 116.12;

(c) All interest attributable to investment of money deposited in the fund; and

(d) All money received in the form of gifts, grants, reimbursement or appropriation from any source for any of the purposes provided in subdivision 2, except federal grants.

Subd. 5. **Recommendation by LCWM.** The legislative commission on waste management shall make recommendations to the standing legislative committees on finance and appropriations regarding appropriations from the fund.

Subd. 6. **Report to legislature.** By November 1, 1984, and each year thereafter, the agency shall submit to the senate finance committee, the house appropriations committee and the legislative commission on waste management a report detailing the activities for which money from the environmental response, compensation and compliance fund has been spent during the previous fiscal year.

Sec. 21.

115B.21. Taxes; definitions

Subdivision 1. **Application.** The definitions provided in this section and section 115B.02 apply to sections 115B.21 to 115B.24.

Subd. 2. **Commissioner.** "Commissioner" means the commissioner of revenue.

Subd. 3. **Generator.** "Generator" means a person who generates hazardous waste and who is required to disclose the generation of hazardous waste under the hazardous waste rules of the agency adopted under section 116.07.

Subd. 4. **Long term containment.** "Long term containment" means land disposal or storage for a period of more than one year.

Subd. 5. **Treatment.** "Treatment" means any material, technique or process designed to change the physical, chemical or biological character or composition of a hazardous waste in order to: (a) neutralize it; (b) render it nonhazardous or less hazardous; (c) render it safer to transport, store or dispose of; (d) make it amenable to storage; or (e) reduce its volume.

Subd. 6. **Wastewater treatment unit.** "Wastewater treatment unit" means a device which is part of a wastewater treatment facility subject to regulation pursuant to the federal Clean Water Act under 33 U.S.C. Section 1317 (b) or 1342.

Sec. 22.

115B.22. Hazardous waste generator tax

Subdivision 1. **Taxes imposed; exclusions.** Each generator of hazardous waste shall pay the taxes imposed by this section based upon the volume and destination of the hazardous wastes generated. The taxes imposed by this section do not apply to hazardous wastes destined for recycling or reuse including waste accumulated, stored, or physically, chemically, or biologically treated before recycling or reuse, to used crankcase oil, to hazardous waste which is generated as a result of any response action, or to hazardous waste which meets applicable pretreatment standards or compliance schedules and is discharged to a public sewage treatment works.

Subd. 2. **Long term containment without treatment.** Hazardous waste destined for long term containment without treatment shall be taxed at the rate of 32 cents per gallon of liquid or $32 per cubic yard of solid.

Subd. 3. **Long term containment after treatment.** Hazardous waste destined for long term containment after treatment shall be taxed at the rate of 16 cents per gallon of liquid or $16 per cubic yard of solid.

Subd. 4. Land treatment. Hazardous waste destined for treatment in or on the land shall be taxed at the rate of $32 per cubic yard.

Subd. 5. Other treatment. Hazardous waste destined for treatment, other than as provided in subdivision 6, to produce a material which is not hazardous, including treatment permitted by the agency in a sewage treatment works, or hazardous waste which is destined for destructive treatment by incineration shall be taxed at the rate of eight cents per gallon of liquid or $8 per cubic yard of solid.

Subd. 6. On-site wastewater treatment. The tax imposed under this section does not apply to hazardous waste which is destined for treatment in an on-site wastewater treatment unit to produce a material which is not hazardous before entering a public sewer system or waters of the state but the tax does apply to any residue of treatment which is a hazardous waste.

Subd. 7. Disposition of proceeds. The proceeds of the taxes imposed under this section including any interest and penalties shall be deposited in the fund.

Subd. 8. Review of tax by LCWM. After the waste management board submits the plan required under section 115A.11 to the legislative commission on waste management, the commission shall review the taxes and tax rates imposed under this section in light of the objectives and recommendations of the plan, and shall recommend to the standing tax committees of both houses of the legislature any changes in the taxes or tax rates which are needed to assist or encourage implementation of the strategies adopted by the state for management of hazardous waste.

Sec. 23.

115B.23 Severability

If any tax imposed under section 115B.22 is found to be invalid because of the purpose for which the proceeds were appropriated or made available under section 115B.20, subdivision 2, the proceeds of that tax shall not be appropriated or available for the objectionable purposes, but the tax shall continue to be imposed and the proceeds shall be appropriated and made available for other purposes provided in section 115B.20, subdivision 2.

Sec. 24.

115B.24. Tax administration and enforcement

Subdivision 1. Annual returns. Every generator of hazardous waste subject to taxation pursuant to section 115B.22 shall file a return relating to the tax due for the preceding calendar year with the commissioner of revenue by April 15 each year, in the form prescribed by the commissioner. Payment of the tax, to the extent not paid in full pursuant to subdivisions 2 and 3, shall be submitted with the return.

Subd. 2. Declarations of estimated tax. For 1983, every generator of hazardous waste required to pay a tax pursuant to section 115B.22 shall make a declaration of estimated hazardous waste generated for the last six months of calendar 1983 if the tax can reasonably be estimated to exceed

$500. The declaration of the estimated tax shall be filed by October 15, 1983. The amount of estimated tax with respect to which a declaration is required shall be paid in two equal installments by October 15, 1983 and January 15, 1984. For 1984 and subsequent years, every generator of hazardous waste required to pay a tax pursuant to section 115B.22 shall make a declaration of estimated hazardous waste generated for the calendar year if the tax can reasonably be expected to be in excess of $1,000. The declaration of estimated tax shall be filed by March 15. The amount of estimated tax with respect to which a declaration is required shall be paid in four equal installments on or before the 15th day of March, June, September, and December.

An amendment of a declaration may be filed in any interval between installment dates prescribed above but only one amendment may be filed in each interval. If an amendment of a declaration is filed, the amount of each remaining installment shall be the amount which would have been payable if the new estimate had been made when the first estimate for the calendar year was made, increased or decreased, as the case may be, by the amount computed by dividing

(1) the difference between (A) the amount of estimated tax required to be paid before the date on which the amendment was made, and (B) the amount of estimated tax which would have been required to be paid before that date if the new estimate had been made when the first estimate was made, by

(2) the number of installments remaining to be paid on or after the date on which the amendment is made.

The commissioner of revenue may grant a reasonable extension of time for filing any declaration but the extension shall not be for more than six months.

Subd. 2. **Failure to pay estimated tax.** (a) In case of any underpayment of estimated tax required by this section, except as provided in clause (b), there shall be added to the tax for the taxable year an amount determined at the rate specified in section 270.75, subdivision 4, upon the amount of the underpayment for the period of the underpayment.

For purposes of this subdivision, the amount of the underpayment shall be the excess of

(1) the amount of the installment, over

(2) the amount, if any, of the installment paid on or before the last date prescribed for payment.

The period of the underpayment shall run from the date the installment was required to be paid to whichever of the following dates is the earlier:

(1) April 15, or

(2) With respect to any portion of the underpayment, the date on which the portion is paid. For purposes of this paragraph, a payment of estimated tax on any installment date shall be considered a payment of any

previous underpayment only to the extent the payment exceeds the amount of the installment determined under this subdivision for the installment date.

(b) Notwithstanding the provisions of clause (a), the addition to the tax with respect to any underpayment of any installment shall not be imposed if the total amount of all payments of estimated tax made on or before the last date prescribed for the payment of the installment equals or exceeds the amount which would have been required to be paid on or before that date if the estimated tax were the lesser of:

(1) For 1985 and thereafter, the tax shown on the return of the taxpayer for the preceding year or, for 1984, twice the amount of the tax shown for 1983; or

(2) Eighty percent of the actual liability for the year.

Subd. 4. **Refunds of overpayments of estimated tax.** Refunds of overpayments of estimated tax shall be made as provided in section 290.936.

Subd. 5. **Exchange of information.** Notwithstanding the provisions of section 116.075, the pollution control agency may provide the commissioner of revenue with the information necessary for the enforcement of section 115B.22 and this section. Information disclosed in a return filed pursuant to this section is public. Information exchanged between the commissioner and the agency is public unless the information is of the type determined to be for the confidential use of the agency pursuant to section 116.075 or is trade secret information classified pursuant to section 13.37. Information obtained in the course of an audit of the taxpayer by the department of revenue shall be nonpublic or private data to the extent that it is not directly divulged in a return of the tax.

Subd. 6. **Payment by out-of-state generators.** A generator of any hazardous waste which is generated outside of this state and is transported into this state for long term containment or treatment as described in section 115B.22, subdivisions 2 to 5 shall pay the tax imposed by section 115B.22 at the first point at which the hazardous wastes are received by a person in this state for storage, treatment or long term containment. The tax shall be paid to the person who first receives the wastes in this state at the time the waste is received and shall be remitted by that person to the commissioner of revenue quarterly in the form and manner provided by the commissioner.

Subd. 7. **Duties of the agency and metropolitan counties.** The agency shall provide to the commissioner the names and addresses of all persons known to the agency who are subject to tax under section 115B.22, together with any information which the agency possesses concerning the amount of hazardous waste generated and disposed of by those persons. Metropolitan counties required to regulate hazardous wastes under section 473.811, subdivision 5b, shall provide to the agency the data and information necessary to allow the agency to carry out its duties under this subdivision. Upon request by the commissioner, the agency shall examine returns and reports filed with the commissioner and notify the commissioner of any suspected inaccurate or fraudulent declaration or return. The agency may assist in auditing any person subject to tax under section 22 when requested by the commissioner.

Subd. 8. **Penalties; enforcement.** The audit, penalty and enforcement provisions applicable to taxes imposed under chapter 290 apply to the taxes imposed under section 115B.22 and those provisions shall be administered by the commissioner.

Subd. 9. **Rules.** The commissioner may adopt temporary and permanent rules necessary to implement the provisions of this section and section 115B.22.

Subd. 10. **Administrative expenses.** Any amount expended by the commissioner from a general fund appropriation to enforce and administer section 115B.22 and this section shall be reimbursed to the general fund and the amount necessary to make the reimbursement is appropriated from the fund to the commissioner of finance for transfer to the general fund.

Sec. 25.

116.12 Hazardous waste administration fees

Subdivision 1. **Fee schedules.** The agency shall establish the fees provided in subdivisions 2 and 3 in the manner provided in section 16A.128 to cover the amount appropriated from the general fund to the agency for that year for permitting, monitoring, inspection and enforcement expenses of the hazardous waste activities of the agency.

The legislature may appropriate additional amounts that need not be covered by fees or may provide that the fees shall cover only a portion of the general fund appropriation for the hazardous waste activities of the agency, in order to assure adequate funding for the regulatory and enforcement functions of the agency related to hazardous waste. All fees collected by the agency under this section shall be deposited in the general fund.

Subd. 2. **Hazardous waste generator fee.** Each generator of hazardous waste shall pay a fee on the hazardous waste which he generates. The agency shall compute the amount of the fee due based on the hazardous waste disclosures submitted by the generators and other information available to the agency. The agency shall annually prepare a statement of the amount of the fee due from each generator. The fee shall be paid annually commencing with the first day of the calendar quarter after the date of the statement.

The agency may exempt generators of small quantities of hazardous wastes otherwise subject to the fee if it finds that the cost of administering a fee on those generators is excessive relative to the proceeds of the fee. The fee shall consist of a minimum fee for each generator not exempted by the agency and an additional fee based on the quantity of wastes generated by the generator.

If any metropolitan counties recover the costs of administering county hazardous waste regulations by charging fees, the fees charged by the agency outside of those counties shall not exceed the fees charged by those counties. The agency shall not charge a fee in any metropolitan county which charges such a fee. The agency shall impose a fee calculated as a surcharge on the fees charged by the metropolitan counties and by the agency to reflect the agency's expenses in carrying out its statewide hazardous waste regulatory responsibilities. The surcharge imposed on the fees charged by the metropolitan counties shall be collected by the metropolitan counties in the manner in which the counties collect their generator fees. Metropolitan counties shall remit the proceeds of the surcharge to the agency by the last day of the month following the month in which they were collected.

Subd. 2. **Facility fees.** The agency shall charge an original permit fee, a reissuance fee and an annual operator's fee for any hazardous waste facility regulated by the agency. The agency may include reasonable and necessary costs of any environmental review required under chapter 116D in the original permit fee for any hazardous waste facility.

Sec. 26. Minnesota Statutes 1982, section 115A.24, subdivision 1, is amended to read:

Subdivision 1. **Certificate.** ~~Except as provided in subdivision 2,~~ By December 15, 1982, on the basis of and consistent with its hazardous waste management plan adopted under section 115A.11, the board shall issue a certificate or certificates of need for disposal facilities for hazardous wastes in the state. The certificate or certificates shall indicate the types and volumes of waste for which disposal facilities are and will be needed through the year 2000 and the number, types, sizes, general design and operating specifications, and function or use of the disposal facilities needed in the state. The board shall certify need only to the extent that the board has determined that there are no feasible and prudent alternatives including waste reduction, separation, pretreatment, processing, and resource recovery which would minimize adverse impact upon natural resources, provided that the board shall require the establishment of at least one commercial disposal facility in the state. Economic considerations alone shall not justify certification nor the rejection of alternatives. Alternatives that are speculative and conjectural shall not be deemed to be feasible and prudent. The board shall consider all technologies being developed in other countries as well as in the United States when it considers the alternatives to hazardous waste disposal. The certificate or certificates shall not be subject to the provisions of chapter 14 but shall be the final determination required on the matters decided by the certificate or certificates and shall have the force and effect of law. The certificate or certificates shall not be amended for five years. The board and the permitting agencies, in reviewing and selecting sites, completing environmental impact statements, and issuing approvals and permits for waste disposal facilities described in the certificate or certificates of need, shall not reconsider matters determined in the certification. The board and the permitting agencies shall be required to make a final decision approving the establishment of facilities consistent with the certification. The board and the permitting agencies shall be required to make a final decision approving the establishment of at least one commercial disposal facility for hazardous waste in the state.

Sec. 27. Minnesota Statutes 1982, section 466.01, is amended by adding a subdivision to read:

Subd. 8. For the purposes of sections 466.01 to 466.15, "release" and "hazardous substance" have the meanings given in section 115B.02.

Sec. 28. Minnesota Statutes 1982, section 466.04, subdivision 1, is amended to read:

Subdivision 1. Limits; punitive damages. Liability of any municipality on any claim within the scope of sections 466.01 to 466.15 shall not exceed

(a) $100,000 when the claim is one for death by wrongful act or omission and $100,000 to any claimant in any other case;

(b) $300,000 for any number of claims arising out of a single occurrence~~.~~;

(c) Twice the limits provided in clauses (a) and (b), but not less than $300,000 per claim, when the claim arises out of the release or threatened release of a hazardous substance, whether the claim is brought under sections 115B.01 to 115B.15 or under any other law.

No award for damages on any such claim shall include punitive damages.

Sec. 29. **Recommendations concerning allocation of liability.**

The waste management board shall make recommendations to the legislature by November 1, 1983 regarding the allocation of liability among the owners, operators, and users of a hazardous waste disposal facility established pursuant to sections 115A.18 to 115A.30, including any recommended legislative changes, taking into consideration the need for the facility, the state's involvement in the facility, the need to protect the health, property and environment of the local community from injury and loss, and the need for incentives to encourage the development and use of alternatives to land disposal. The recommendations shall be made after consultation with affected industries, including insurers, generators, transporters, disposers, and treaters of hazardous waste, individuals, including academic, scientific and legal professionals, and groups, including community and environmental groups.

Sec. 30. **Victim compensation study.**

By July 1, 1984, the legislative commission on waste management shall conduct a study and make recommendations to the legislature on the creation of a compensation fund to compensate persons who are injured as the result of a release of a hazardous substance and who would not otherwise be adequately compensated for their injuries. The study shall consider matters including the following:

(a) The appropriate scope of compensation which should be provided by the fund including the extent of any compensation which should be available for medical expenses, disability, loss of income, physical impairment, and death;

(b) Creation of a simple, speedy, and cost efficient claims procedure which provides an effective remedy for injured claimants;

(c) Methods by which compensation can be financed by those who create or contribute to the risk of injury from hazardous substance releases, including the manner by which the state may seek to recover amounts paid from the fund; and

(d) Whether the fund should be established or administered at the federal or state level and the appropriate degree of state and federal cooperation in providing compensation.

Sec. 31. Insurance study.

The commissioner of insurance shall conduct a study of insurance providing coverage for liability under section 5. The commissioner shall submit the results of the study, together with his recommendations, to the legislature by July 1, 1985. The director of the pollution control agency shall cooperate with and provide assistance to the commissioner during the course of the study.

Sec. 32. Appropriation; complement.

Subdivision 1. Appropriation to fund. $5,000,000 is appropriated from the general fund and transferred to the environmental response, compensation, and compliance fund established in section 20. This appropriation is available until expended.

Subd. 2. Tax administration; complement. $50,000 in fiscal year 1984 and $40,000 in fiscal year 1985 is appropriated from the general fund to the commissioner of revenue for the purposes of administering and enforcing sections 21 to 24. This appropriation shall be reimbursed to the general fund under the provisions of section 24, subdivision 10.

The complement of the department of revenue is increased by two positions.

Subd. 3. Appropriation for response actions; complement. $483,700 in fiscal year 1984 and $400,700 in fiscal year 1985 is appropriated from the environmental response, compensation, and compliance fund to the pollution control agency for administrative costs.

The complement of the pollution control agency is increased by ten positions.

All money in the environmental response, compensation, and compliance fund not otherwise appropriated is appropriated to the pollution control agency for the purposes described in section 20, subdivision 2, clauses (a), (b), and (c). This appropriation is available until June 30, 1985.

Subd. 4. Appropriation for compliance actions; complement. $45,600 in fiscal year 1984 and $56,400 in fiscal year 1985 is appropriated from the general fund to the attorney general for the purposes of enforcing this act.

This appropriation shall be reimbursed to the general fund from the environmental response, compensation, and compliance fund, and the amount necessary to make the reimbursement is appropriated to the commissioner of finance for transfer to the general fund.

The complement of the office of the attorney general is increased by two positions.

Subd. 5. **Appropriation for victim compensation study.** $20,000 is appropriated from the general fund to the legislative commission on waste management to carry out the study required by section 30.

Subd. 6. **Appropriation for insurance study.** There is appropriated from the general fund to the commissioner of insurance $5,000 for fiscal year 1984, to conduct the study described in section 31.

Sec. 33. **Repealer.**

Minnesota Statutes 1982, section 115A.24, subdivision 2, is repealed.

Sec. 34. **Effective date.**

Sections 17 to 24 are effective the day following final enactment. The taxes imposed by section 22 are effective July 1, 1983. The remaining sections of this act are effective July 1, 1983.

Approved May 10, 1983.

Summary of the 1983 Superfund Bill:

Environmental Response and Liability Act*

The Environmental Response and Liability Act (Superfund) has three main purposes:

(1) To establish a statutory standard of strict liability for the release of hazardous substances;

(2) To establish authority for the state to respond to releases of hazardous substances;

(3) To create a fund to pay for the cleanup of sites not covered by the Federal Superfund and to provide that money from the Environmental Response Fund could be used for the 10% state match required by the Superfund Act as a condition for receipt of federal cleanup money.

Citizens have become increasingly aware of the serious threats to public health and the environment posed by the discovery of hazardous wastes not only at sites such as Love Canal in New York, but at sites within our own state, such as St. Louis Park, Fridley, New Brighton, and Oakdale. At the time the bill was being considered by the 1982 Legislature, the Minnesota Pollution Control Agency had identified 49 contaminated hazardous waste sites within the state in need of cleanup; that number has now grown to 61. The question then arises: what can be done to clean up those existing sites which are the result of past improper handling of hazardous wastes and what can be done to help prevent future improper handling of hazardous waste?

One way to guard against future hazardous waste incidents would be to make sure that all those associated with the generation, transport and disposal of hazardous waste use the greatest degree of care possible. In order to help accomplish this, the bill establishes a statutory standard of strict, joint and several liability.

Strict, Joint and Several Liability

Strict liability is now a part of the common law and many people are familiar with it in the context of the use of dynamite. When a person is engaged in an ultrahazardous or inherently dangerous activity, the law now provides that that person is liable for the damages which result from that activity without regard to fault. Even though he takes all possible precautions and the damages are not caused by his negligence, the person engaged in the activity will still be liable.

While some other states have enacted laws establishing strict liability and while courts in some other states have applied strict liability for injuries caused by hazardous substances, no case has been decided yet which clearly establishes the standards of liability that will apply in Minnesota. The Superfund establishes the standard of liability in statute.

*The bill was originally introduced in 1981, when is was heard in only one committee. In 1982 it was heard in 12 committees and subcommittees, passed both the House and Senate by wide margins, but was vetoed by the Governor. The bill again passed the Legislature in 1983 and was signed into law by the Governor on May 10.

Risks from hazardous substances can never be completely eliminated. A person engaged in an activity involving hazardous substances may take all precautions that are humanly and technologically possible to limit risk and yet an innocent person may still be injured as a result of exposure to a release. Those supporting the Superfund believe the question this raises is one of fundamental fairness -- should the loss fall on the innocent victim who is injured or on the person who created the risk? The policy of the act is that the loss should fall on persons who create the risk and who are in the best position to control the causes of injury. Thus, those who profit from the use of the substances will bear the cost of any injuries, not the innocent victims of those injuries.

The act provides that persons who are found liable for injuries or cleanup costs are liable jointly and severally. Under existing law, when several parties contribute by their actions to the same injury they are jointly liable for the consequences. If there is joint liability, then under existing Minnesota law the liability is also joint and several (Minnesota Statutes § 604.02, Subdivision 1). In its usual form, joint and several liability means that the injured party may recover his damages against each defendant or any of them, up to 100 percent of the total liability.

It should be pointed out that, in enforcing the federal Superfund law, the Environmental Protection Agency and Department of Justice are applying strict, joint and several liability for the cleanup of contaminated sites.

Limitations and Exceptions to Liability

A number of important exceptions and defenses to liability were added to the act as a result of discussions with interested parties to assure greater fairness in applying the general rule of strict, joint and several liability. Some of these exceptions are summarized here.

Limitation on liability for past acts: Strict, joint and several liability for damages resulting from past acts would apply where wastes were deposited after 1973; between 1960 and 1973, it would apply only if the responsible person's activity would have been abnormally dangerous at that time. It would not apply for wastes deposited prior to 1960.

There is a limitation on joint and several liability in the act. The act provides that liability can be divided up among the defendants according to their degree of responsibility, and no defendant can be required to pay more than two times his apportioned share for personal injury or economic loss. Full joint and several liability would apply for cleanup. Any defendant who has to pay more than his apportioned share can sue other defendants to recover the excess.

There is no liability for either damages or cleanup for the innocent property owner who discovers hazardous substances which were buried on his property without his knowledge or consent and if he has not associated himself with the release.

There is no liability for application of farm or forestry chemicals or for disposal of pesticide containers and residues according to instructions on product labels.

There is no liability if the release is due to an unforeseeable event like a tornado, theft, or vandalism or due to the act of an unrelated third party.

There is no liability for garbage haulers unless they knew or reasonably should have known they were carrying the particular hazardous substance that later causes injury.

There is no liability for a transporter of hazardous waste unless he selected the facility to which the waste was taken or disposed of the waste in a manner contrary to law.

And there is no liability if the state or federal government has issued a permit which allows discharge of the hazardous substances and if the terms of the permit are being fulfilled.

With these limitations the act sets a standard of liability which would give injured parties a fair chance to recover for their injury or loss and it assists the state in recovering its cleanup costs from the party responsible for the contamination.

But what if the person responsible for the release of a hazardous substance cannot be determined or is found to be insolvent? Who then will pay for the cleanup of hazardous waste sites? The act establishes the Environmental Response, Compensation and Compliance Fund to do this. It will be funded from two sources: a general fund appropriation of $5 million for the biennium and a tax on generators of hazardous waste which is expected to raise about $900,000 annually.

State Authority to Clean Up Contaminated Sites

The Superfund authorizes the state Pollution Control Agency (PCA) to take removal or remedial action when there is a release or threatened release of a hazardous substance or any pollutant or contaminant which may present an imminent or substantial danger.

Prior to passage of the act, the PCA did not have the necessary authority and funds to adequately prevent or minimize environmental contamination from hazardous waste. In some cases the responsible parties were unknown or bankrupt. When a responsible party had been identified the PCA could request, demand or attempt to negotiate the desired cleanup action. However, if this effort was unsuccessful, the only option left to the PCA was to file a lawsuit. The result was litigation which could take years to reach a conclusion. In the meantime, toxic chemical contamination progressively spread deeper into the groundwater systems increasing the environmental damage and cost of cleanup. The authority given to PCA under Superfund would permit it to directly address these problems by allowing to "clean up first, litigate later."

Tax on Generators of Hazardous Wastes

The tax in the act is based on the amount of waste generated and o the ultimate disposition of the waste. The highest tax is on waste whi is to be landfilled without treatment -- $32.00 per cubic yard or 32¢ p gallon.

Hazardous wastes destined for long-term containment after treatmen will be taxed at $16.00 per cubic yard or 16¢ per gallon.

Hazardous wastes which are incinerated or chemically treated will taxed at $8.00 per cubic yard or 8¢ per gallon.

The purpose of the tax is threefold and is consistent with the purposes of the 1980 Waste Management Act: (1) to encourage a reducti the amount of hazardous waste generated; (2) to encourage the treatmen and processing of hazardous waste rather than land disposal; and (3) t raise revenue to clean up areas which have been contaminated by hazard wastes.

The question then arises: How much money will be needed to clean hazardous waste sites in this state?

After passage of the federal "Superfund" act in late 1980, it was hoped that the federal government would clean up a major portion of th contaminated sites around the country. However, it has since been rec nized by all interested parties that the Superfund will be inadequate respond to all hazardous waste sites. In fact, EPA has indicated that there may be as many as 9,000 hazardous waste sites across the countr At the same time, EPA officials have indicated to Congress that Super may only provide for the actual cleanup of 170 sites. Thus, states w be responsible for sites not covered by Superfund, as well as for pro matching money for sites that may receive Superfund monies. These st responsibilities will result in the need for enormous amounts of mone

It is difficult to say precisely just how enormous the need will in Minnesota. We will probably get Superfund dollars to clean up onl few of our contaminated sites. There are now 61 sites contaminated b hazardous waste in the state which are in need of cleanup. The cost cleanup at each of these sites varies widely, ranging from several hu thousand dollars to many millions. The Pollution Control Agency esti that it will cost about $50 million to clean up all of the sites dis thus far. Additional money will be needed if more contaminated site found.

Support for the Superfund Act

The act had broad support from the League of Minnesota Cities, Association of Metropolitan Municipalities, the Association of Minne Counties, the Metropolitan Inter-County Association, the League of W Voters, the Minnesota AFL-CIO, the Farmers Union, Minnesota COACT, t Sierra Club, the Izaak Walton League, the Minnesota Audubon Council, Minnesota Trial Lawyers Association, the Joint Religious Legislative Conference and the Minnesota Catholic Conference. In addition, maj newspapers around the state urged passage of the bill.

HOUSE RESEARCH

Bill Summary

H.F. 76 S.F.

SUBJECT: Hazardous Waste Superfund (passed by House 4/18/83)

AUTHORS: Long, Munger, Simoneau, Sieben, Evans

COMMITTEE:

DATE: 4/25/83

OVERVIEW

This bill has three main purposes:

(1) To establish a statutory standard of strict liability for the release of hazardous substances;

(2) To establish authority for the state to respond to releases of hazardous substances;

(3) To create a fund to pay for the cleanup of sites not covered by the federal Superfund and to provide that money from the state Superfund could be used for the 10% state match required by the federal Superfund law as a condition for receiving federal cleanup money.

SECTION BY SECTION SUMMARY

Section 1. CITATION. Sections 1 to 19 are the "Environmental Response and Liability Act."

Section 2. DEFINITIONS.

Subd. 3. "Agency" means the state pollution control agency (PCA).

Subd. 5. "Facility" includes buildings, structures, pits, ponds, landfills, vehicles and other sites where a hazardous substance, pollutant or contaminant has been deposited.

Subd. 8. "Hazardous substance" includes certain chemicals and hazardous air pollutants as designated by federal law and hazardous wastes. The term does not include certain natural and synthetic gases, nor petroleum.

Subd. 9. "Hazardous Waste" means those substances identified as hazardous waste according to state or federal law.

Legislative Analyst: Stan Jacobson 296-1885

Phone:

Subd. 12. "Person" includes individuals, partnerships, corporations, the federal government, the state and political subdivisions of the state.

Subd. 13. "Pollutant or contaminant" includes substances which may cause death or disease in organisms. Certain natural and synthetic gases are excluded.

Subd. 14. "Release" includes spilling, dumping or otherwise discharging into the environment either on a single occasion or continuously. The term does not include engine exhausts, nuclear releases, and applications of fertilizer.

Subd. 15. "Remedy" includes actions taken instead of or in addition to removal actions to prevent, minimize or eliminate the release of a hazardous substance, pollutant or contaminant in order to protect the public health, welfare or environment.

Subd. 16. "Removal" includes actions taken to clean up or remove a released hazardous substance, pollutant or contaminant from the environment.

Subd. 17. "Response" includes both remedy and removal actions.

Section 3. RESPONSIBLE PERSON

Subd. 1. GENERAL RULE. Defines who is responsible for the release of a hazardous substance, pollutant or contaminant. Responsible persons include those who operate a facility, and those who possess or transport, and arrange for disposal, of the hazardous substance, pollutant or contaminant.

Subd. 2. EMPLOYEES AND EMPLOYERS. If an employee has acted within the scope of his employment, he is personally liable for the release of a hazardous substance only if he was negligent; his employer is liable whether or not the employee was negligent.

Subd. 3. OWNER OF REAL PROPERTY. A landowner is not responsible for the release of a hazardous substance unless he knew about or cooperated with the disposal activities.

Section 4. LIABILITY FOR RESPONSE COSTS AND NATURAL RESOURCES.

Subd. 1. LIABILITY. A person responsible for the release of a hazardous substance is strictly liable for the costs of removal by anyone and of remedy by the government, as well as for harm to natural resources. All responsible persons are jointly and severally liable under this section.

Subd. 2. EXCLUDES POLLUTANT OR CONTAMINANT. There is no liability under this section for the release of a pollutant or contaminant.

Subd. 3. THREATENED RELEASE. Liability for a threatened release of a hazardous substance is limited to the response costs of the PCA.

Subd. 4. POLITICAL SUBDIVISIONS. Limits on the liability of a political subdivision are provided in section 26.

Subd. 5. HOUSEHOLD REFUSE. A transporter of household refuse is not liable under this section for the release of a hazardous substance unless he knew, or should have known, that the hazardous substance was in the refuse.

Subd. 6. DEFENSE TO CERTAIN RESPONSE CLAIMS. If a "response action" (clean up, etc.) was not authorized by the PCA, neither a political subdivision nor a private person can recover under this section for the costs of the response action for any hazardous substance placed in a facility before April 1, 1982.

Subd. 7. DEFENSE FOR INTERVENING ACTS. Someone who would ordinarily be responsible for the release of a hazardous substance is not liable under this section if the release was caused solely by an act of God, war or a "third party" (vandals, etc.).

Subd. 8. PERMITTED RELEASES. There is no liability under this section if the release of a hazardous substance was permitted by the state or federal government, or if liability has been assumed under federal law.

Subd. 9. NATURAL RESOURCES. There is no liability under this section for harm to natural resources if the harm was identified as an irretrievable commitment of natural resources according to state or federal law.

Subd. 10. RENDERING ASSISTANCE TO THE GOVERNMENT. There is no liability under this section for harm which resulted while providing aid to the PCA or to federal authorities.

Subd. 11. BURDEN OF PROOF. Puts the burden of proof for the defenses in subdivisions 6 to 10 on the defendant.

Section 5. LIABILITY FOR ECONOMIC LOSS, DEATH, PERSONAL INJURY AND DISEASE.

Subd. 1. LIABILITY. A person responsible for the release of a hazardous substance is strictly liable for all resulting actual economic losses, death, personal injury and disease. All responsible persons are jointly and severally liable under this section.

Subd. 2. EXCLUDES POLLUTANT OR CONTAMINANT. There is no liability under this section for the release of a pollutant or contaminant.

Subd. 3. CERTAIN EMPLOYEE CLAIMS. There is no liability under this section if a claim for personal injury or disease is compensable under the workers compensation law.

Subd. 4. LIABILITY LIMITS. The liability of a political subdivision or a small business under this section is limited to $300,000 per person and $600,000 per occurrence. The liability of anyone else under this section is limited to $1.5 million.

Subd. 5. HOUSEHOLD REFUSE. A transporter of household refuse is not liable under this section for the release of a hazardous substance unless he knew, or should have known, that the hazardous substance was in the refuse.

Subd. 6. DEFENSE FOR INTERVENING ACTS. Someone who would ordinarily be responsible for the release of a hazardous substance is not liable under this section if the release was caused solely by an act of God, war or a third party.

Subd. 7. PERMITTED RELEASES. There is no liability under this section if the release of a hazardous substance was permitted by the state or federal government, or if liability has been assumed under federal law.

Subd. 8. RENDERING ASSISTANCE TO THE GOVERNMENT. There is no liability under this section for harm which resulted while providing aid to the PCA or to federal authorities.

Subd. 9. DEFENSE FOR CERTAIN PAST ACTIONS. There is no liability under this section if the hazardous substance was placed in the facility before April 1, 1982 and the defendant's activities were not abnormally dangerous. The standards provided in existing Minnesota common law are used to decide whether the defendant's activities were abnormally dangerous.

Subd. 10. BURDEN OF PROOF. Puts the burden of proof for the defenses in subdivisions 6 to 9 on the defendant.

Section 6. CAUSATION. Provides a method that is easier than under current law for the claimant to prove that his injury was caused by the release of a hazardous substance.

Section 7. APPORTIONMENT. (Rules for determining who pays how much among several defendants.)

Subd. 1. APPORTIONMENT FACTORS. The jury may apportion liability among the defendants based on factors listed in this subdivision.

Subd. 2. LIMITATION. If a person is held "jointly and severally liable" and if he can prove what his proportionate share is of the aggregate liability, his total liability is limited to three times his proportionate share. (Ordinarily, if a person is held "jointly and severally liable", there is no limit on his total liability.)

Subd. 3. CONTRIBUTION. Anyone who is jointly and severally liable and who pays more than his proportionate share may seek contribution from anyone else who is also liable.

Section 8. TRANSFERRING LIABILITY. No one may avoid liability under this Act by attempting to transfer his own liability to someone else.

Section 9. STATUTE OF LIMITATIONS. A lawsuit claiming damages must be started within six years of the time when the claim could have been made based on the time of discovering the harm and its causal connection to the release of a hazardous substance.

Section 10. OTHER REMEDIES PRESERVED. Any right or remedy available under other state, federal or common law is unaffected by this Act.

Section 11. DOUBLE RECOVERY PROHIBITED. No one may recover twice for the same costs or damages.

Section 12. APPLICATION OF SECTIONS 1 TO 12. Sections 1 to 12 do not apply to the release of a hazardous substance which occurred entirely before July 1, 1983, regardless of the date of discovery of harm caused by the release.

Section 13. DISPOSITION OF FACILITIES.

Subd. 1. USE OF A CLOSED FACILITY. No one may disturb the containment or monitoring systems on any property in which hazardous waste remains after the facility is closed, unless authorized to do so by the PCA.

Subd. 2. RECORDING AFFIDAVIT. If a landowner knows that his property was used as a disposal site for hazardous waste or that there has been extensive contamination by release of a hazardous substance, the owner must file an affidavit with the county recorder to that effect.

Subd. 3. DUTY OF COUNTY RECORDER. The county recorder must record any affidavit or notation made under subdivision 2 so that disclosure is assured during a title search.

Subd. 4. PENALTIES. Anyone who knowingly violates either subdivision 1 or 2 may be liable for all costs and damages recoverable under sections 4 and 5. In addition, anyone knowingly violating subdivision 1 may be liable for a civil fine not exceeding $100,000.

Section 14. STATE RESPONSE TO RELEASES

Subd. 1. REMOVAL AND REMEDIAL ACTIONS. The PCA may take any removal or remedial action necessary to protect public health, welfare or the environment. These actions may be taken whenever there is a release or a threatened release of a hazardous substance and whenever there is a release or a substantial threat of a release of a pollutant or contaminant presenting an imminent and substantial danger to the public. The PCA must first request any person known to be responsible to take the necessary actions. However, the director has special powers to act quickly in an emergency.

Subd. 2. OTHER ACTIONS. The PCA may gather information about the extent of the release or threatened release of a hazardous substance, pollutant or contaminant and undertake studies in order to carry out removal or remedial actions.

Subd. 3. DUTY TO PROVIDE INFORMATION. Anyone responsible for a release or a threatened release of a hazardous substance, pollutant or contaminant must provide the PCA with relevant information.

Subd. 4. ACCESS TO INFORMATION AND PROPERTY. The PCA may examine written records and enter onto property in order to carry out its duties under this section.

Subd. 5. CLASSIFICATION OF DATA. In general, information obtained by the PCA under subdivisions 3 and 4 is public data. However, the subject of the information may apply to the director of the PCA for classification of the data as private or nonpublic.

Subd. 6. RECOVERY OF EXPENSES. The PCA may recover the expenses it incurs in carrying out its duties under this section in a civil action against a responsible person.

Subd. 7. ACTIONS RELATING TO NATURAL RESOURCES. The state is the trustee of the air, water and wildlife of the state. Actions for damages to the air, water or wildlife are brought in the name of the state as trustee.

Subd. 8. ACTIONS RELATING TO PESTICIDES, FERTILIZER, ETC. Transfers the PCA's powers under this section to the commissioner of agriculture if the release of a hazardous substance, pollutant or contaminant involves pesticides, fertilizers, soil or plant amendments.

Subd. 9. ACTIONS RELATING TO OCCUPATIONAL SAFETY. Directs the PCA and the commissioner of labor and industry to coordinate their actions regarding a release or threatened release affecting occupational safety.

Subd. 10. ACTIONS RELATING TO HEALTH. Directs the PCA and the commissioner of health to coordinate their actions regarding a release or threatened release affecting public health.

Subd. 11. LIMIT ON ACTIONS BY POLITICAL SUBDIVISIONS. No political subdivision may order anyone to act in a way which conflicts with a request by the PCA.

Subd. 12. AUTHORIZATION OF CERTAIN RESPONSE ACTIONS. The PCA may authorize a political subdivision or a private person to take certain response actions regarding hazardous substances placed in a facility before April 1, 1982. This authorization will permit the political subdivision or private person to recover costs under section 4.

Subd. 13. PRIORITIES; RULES. The PCA must adopt a temporary list and permanent rules for setting priorities to take remedial action.

Section 15. MISCELLANEOUS CIVIL REMEDIES.

Subd. 1. CIVIL PENALTIES. Any responsible person who fails to make reasonable progress in completing response actions requested by the PCA is liable to the state for a civil penalty up to $25,000 per day.

Subd. 2. ACTION TO COMPEL PERFORMANCE. The attorney general may sue to compel performance by any responsible person who fails to make reasonable progress in completing response actions requested by the PCA.

Subd. 3. REQUESTS FOR RESPONSE ACTIONS. Requests by the PCA for a responsible person to take response actions must be in writing and provide a reasonable time for the action to be taken.

Subd. 4. INJUNCTIVE RELIEF. The release or threatened release of a hazardous substance, pollutant or contaminant is a public nuisance which the state may seek to enjoin.

Section 16. PURPOSES OF FUND AND TAXES. Establishes the purposes of the environmental response, compensation and compliance fund (the "state superfund"), including protection of public health, reduction of hazardous waste through recycling and placing the financial burden of state waste management activities on those who produce these wastes.

Section 17. ENVIRONMENTAL RESPONSE, COMPENSATION AND COMPLIANCE FUND. (THE "STATE SUPERFUND.")

Subd. 1. ESTABLISHMENT. Creates the "state superfund."

Subd. 2. PURPOSES. Lists the purposes for which the money in the fund may be spent, including response actions by the PCA, reimbursement for alternative water supplies, compensating a community in which a hazardous waste site is established under state law, restoring natural resources, and the PCA's expenses in monitoring compliance by commercial facilities.

Subd. 3. LIMITS ON CERTAIN PAYMENTS. Requires the PCA to coordinate payments from the state superfund with payments from the federal superfund.

Subd. 4. REVENUE SOURCES. Lists revenue sources for the state superfund including taxes imposed by section 20 and other fees.

Subd. 5. RECOMMENDATION BY LCWM. Requires the legislative commission on waste management to make recommendations to standing legislative committees concerning appropriations from the state superfund.

Subd. 6. REPORT TO LEGISLATURE. Requires the PCA to submit reports annually to the legislature concerning money spent from the state superfund.

Section 18. RECOMMENDATIONS CONCERNING ALLOCATION OF LIABILITY. Requires the waste management board to make recommendations to the legislature regarding the allocation of liability at the state-sited hazardous waste disposal facility.

Section 19. DEFINITIONS FOR TAXES. Defines terms used in section 20, including "generator" as a person who generates hazardous waste and is required by state law to disclose this fact.

Section 20. HAZARDOUS WASTE GENERATOR TAX.

Subd. 1. TAX IMPOSED. Imposes taxes on hazardous waste generators. Exempts hazardous wastes which are recycled or reused.

Subd. 2. LONG TERM CONTAINMENT WITHOUT TREATMENT. Taxes hazardous waste destined for long term containment at 32¢ per gallon or $32 per cubic yard.

Subd. 3. LONG TERM CONTAINMENT AFTER TREATMENT. Taxes hazardous waste destined for long term containment after treatment at 16¢ per gallon or $16 per cubic yard.

Subd. 4. OTHER TREATMENT. Taxes hazardous waste destined for treatment which will produce nonhazardous material at 8¢ per gallon or $8 per cubic yard.

Subd. 5. LAND TREATMENT. Taxes hazardous waste destined for treatment in or on land at $32 per cubic yard.

Subd. 6. ON SITE WASTEWATER TREATMENT. There is no tax imposed for hazardous waste which is treated at the generator's site to produce nonhazardous material.

Subd. 7. PROCEEDS OF TAXES. The taxes are deposited in the state superfund.

Subd. 8. REVIEW OF TAX BY LCWM. The legislative commission on waste management will make recommendations regarding the hazardous waste generator tax to the legislature.

Section 21. SEVERABILITY. If any tax imposed by section 20 is found invalid, the other taxes shall continue to be imposed.

Section 22. TAX ADMINISTRATION.

Subd. 1. ANNUAL RETURNS. Each person liable for taxes imposed by section 20 must file an annual tax return with the commissioner of revenue.

Subd. 2. DECLARATIONS OF ESTIMATED TAX. If the estimated annual tax exceeds $1,000, quarterly payments must be made.

Subd. 3. FAILURE TO PAY ESTIMATED TAX. If the estimated tax payment is less than 80 percent of the actual tax liability, interest on the unpaid amount accrues at a rate based on the prime rate charged by commercial banks.

Subd. 4. REFUNDS. Provides a refund for overpayments of estimated tax.

Subd. 5 EXCHANGE OF INFORMATION. Authorizes the PCA to provide information to the commissioner of revenue to enforce the tax.

Subd. 6. PAYMENTS BY OUT OF STATE GENERATORS. An out of state generator who transports hazardous waste into Minnesota for long term containment or treatment must pay the tax imposed by section 20.

Subd. 7. CERTAIN METROPOLITAN COUNTIES. Metropolitan counties required by state law to regulate hazardous wastes must provide the PCA with information to carry out its duties.

Subd. 8. PENALTIES. The same penalties provided for other state tax collections apply to the tax imposed by section 20.

Subd. 9. RULES. Authorizes the commissioner of revenue to adopt rules.

Subd. 10. ADMINISTRATIVE EXPENSES. Coordinates payments between the general fund and the state superfund for certain administrative expenses.

Section 23. HAZARDOUS WASTE ADMINISTRATION FEES.

Subd. 1. FEE SCHEDULES. Provides additional fees for the PCA to enforce the hazardous waste laws.

Subd. 2. HAZARDOUS WASTE GENERATOR FEE. Each generator must pay an annual fee for generating hazardous waste. Generators of small quantities of hazardous waste may be exempted.

Subd. 3. FACILITY FEES. Each facility that obtains a permit from the PCA shall pay a permit fee, a reissuance fee and an annual operator's fee.

Section 24. Amends Minn. Stat. Section 115A.24, Subd. 1. A technical amendment required by section 29.

Section 25. Amends Minn. Stat. Section 466.01 to provide definitions of "release" and "hazardous substance" used in section 25.

Section 26. Amends Minn. Stat. Section 466.04, Subd. 1. Provides that a municipality's liability for a release of a hazardous substance is twice its ordinary limits, that is, $200,000 per claimant and $600,000 for all claims from a single occurrence.

Section 27. INSURANCE STUDY. Requires the commissioner of insurance to study and report to the legislature concerning the availability of insurance against liability for personal injury under section 5.

Section 28. APPROPRIATION. Appropriates $5 million to the state superfund.

Section 29. REPEALER. Repeals Minn. Stat. Sec. 115A.24, Subd. 2. which required enactment of this law before any hazardous waste sites could be established.

Section 30. EFFECTIVE DATE. Sections 14 to 22 are effective the day after enactment. All other sections are effective July 1, 1983.

COMPENSATION FOR TOXIC SUBSTANCES EXPOSURE

Work Group (Torzi group will serve as Tech. staff)
Horowitz - OMB Gen. Counsel
Uhlmann
Keyworth - Pres. Science Advisor
Rose

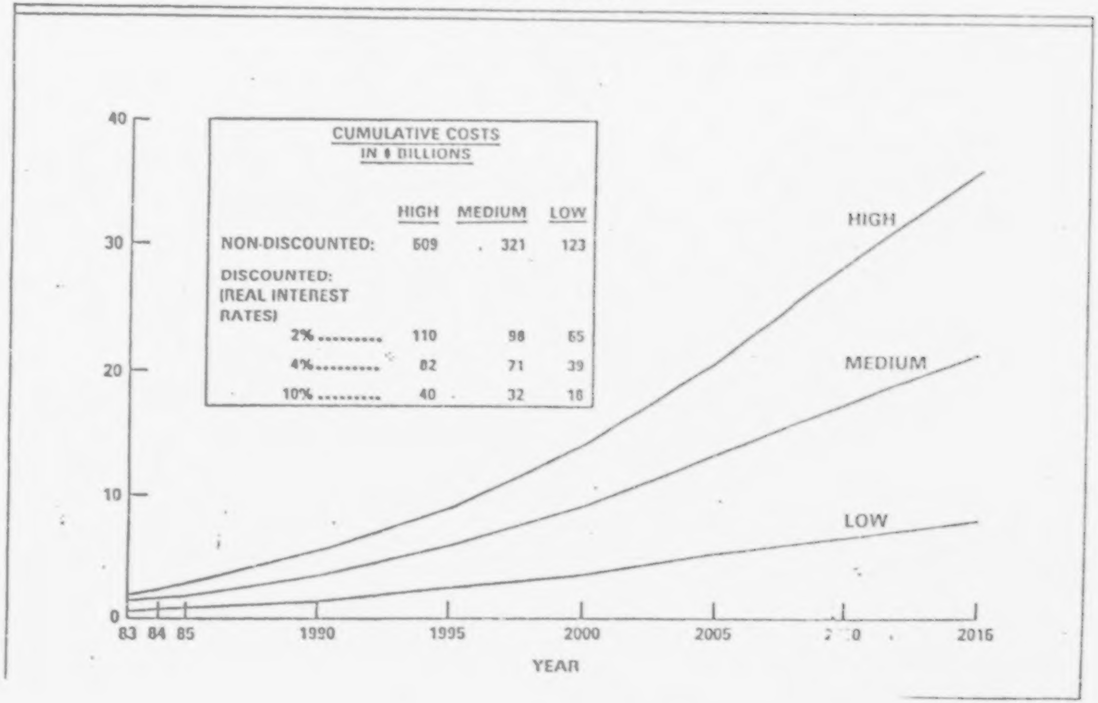
May 19, 1983

I. OVERVIEW

- The Administration is faced with increasing pressure for the creation of administrative compensation systems for persons suffering chronic injuries allegedly caused by exposure to toxic substances, including:
    - asbestos
    - radiation
    - Agent Orange
    - a wide variety of hazardous substances and wastes via Superfund personal injury compensation.
- Considerable legislative action can be expected in this Congress -- with highly publicized hearings and possible action late this year. Immediate concern is scheduled summer hearings on Superfund compensation legislation.
- A prime example is the Miller bill, which would provide compensation for persons exposed to asbestos.
    - A Department of Labor analysis shows potential outlays over next 30 years up to $500 billion, with potential annual expenditures as high as $30 billion/year by 2015. (See Chart 1.)
    - As written, Miller bill funds compensation claims solely through industry contributions, but eventual federal bail-out is inevitable. Bill would necessitate an immediate tax of $1,000/ton of asbestos, increasing to $3,200/ton by 1990 -- compared to current selling price of $340/ton.

ESTIMATED ANNUAL COSTS (HIGH, MEDIUM AND LOW) OF LEADING ASBESTOS OCCUPATIONAL COMPENSATION PROPOSAL 1983 — 2015

$ IN BILLIONS



CUMULATIVE COSTS IN $ BILLIONS

	HIGH	MEDIUM	LOW
NON-DISCOUNTED:	609	321	123
DISCOUNTED: (REAL INTEREST RATES)			
2%	110	98	65
4%	82	71	39
10%	40	32	18

II. HISTORICAL CONTEXT: PARALLELS WITH BREAKDOWN OF POLICY PRINCIPLES DURING EXPLOSIVE 1960'S AND 1970'S GROWTH OF ENTITLEMENTS

- Current toxic substances compensation debate replicates the 1970 era debates over social welfare entitlements. Latter were created with low initial costs, understated long-term cost estimates, and no appreciation for expansionary pressures being set in motion. Today, we are paying for the consequences of "small" steps taken without understanding of long-term policy and fiscal implications.

- Explosive post-1970 growth of Social Security disability and Black Lung compensation -- two existing disability compensation systems directly relevant to the current debate over toxic substances compensation -- underscores long-range threat.

- Just as the 1970's welfare expansion built on the breakdown of conceptual barriers that limited government support to the truly needy, the toxic substances compensation movement is built on the breakdown of principles that link compensation to fault.

- This is a logical consequence of the relentless movement of tort law during the 70's towards absolute liability. This trend is reflected in increasingly stringent product liability doctrines that have converted manufacturers into societal insurers, as well as in the increasing demand for government-sponsored compensation systems.

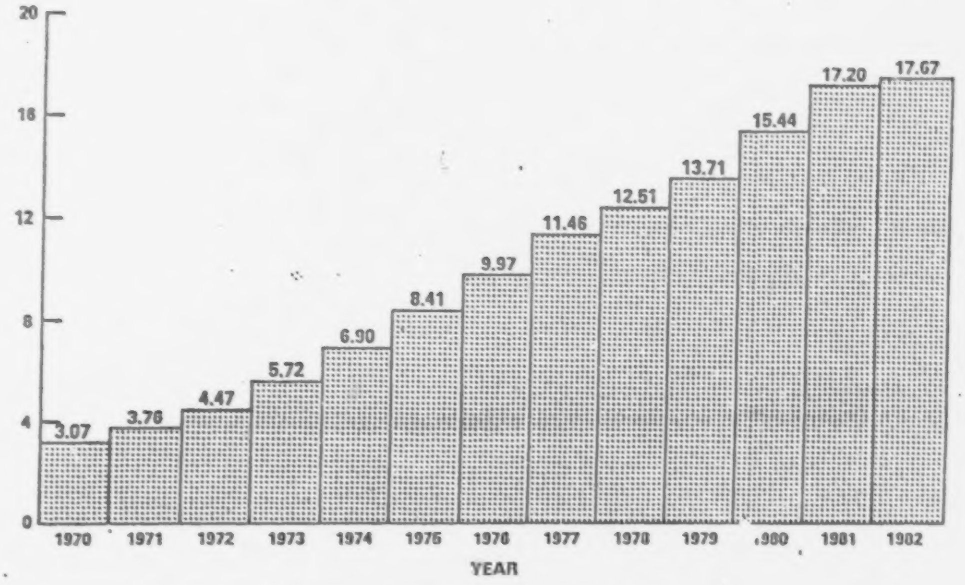
$ IN BILLIONS



HISTORICAL CONTEXT
(continued)

- The incipient movement towards federally financed toxic substances compensation embodies other parallels to 1970's social welfare entitlement expansions, including these:
    - Low initial cost estimates for various compensation schemes -- but once the "right" to government aid or rights of court action are established, the size and cost of programs become politically uncontrollable under constituency pressure for liberalization and expansion.
    - 1970's entitlement expansion preceded by a flood of reports and studies "documenting" the need for the new entitlements, often on the most tenuous of grounds. Dozens of similar studies of toxic torts and compensation are underway. Studies not supporting the case have limited impact, while those that find a need for compensation -- no matter how weak or suspect their conclusions -- serve as the foundation of media attention, hearings, initiatives, etc.
    - Resistence to "modest" first steps in the creation of major entitlement rights poses political difficulties of the highest order -- because it involves the political cost of resisting popular proposals now in order to avoid potentially heavy costs in the more distant future. Failure of earlier administrations to resist 1970's transfer payment expansions is now extremely costly. This Administration will face a similar test with toxic substances compensation -- as full costs will come on-stream in a major sense only during the next decade.
- Unfortunately, the Administration's ability to respond to the growing list of toxic substances compensation proposals is hampered by the lack of centralized policymaking. The Administration's response thus far has been fragmented, and largely determined by individual agencies' unique priorities. As a result, conflicting agency positions have undermined many of the Administration's legislative and litigation efforts.

III. ASBESTOS

- Asbestos Exposure
  - Approximately 13 to 15 million workers were exposed between 1940 and 1980.
  - Estimated total exposed population at 25 to 30 million.
  - Link to certain diseases, including lung cancer, has been definitively established.
- Litigation Status
  - Approximately 20,000 to 25,000 claims already filed.
  - 100,000 to 200,000 are expected in the next two to three decades (see Chart 4).
  - Industry litigation liability may be in excess of $30 billion (see Chart 5) -- probably more than industry assets and available insurance can cover.
- Fiscal Threat
  - Federal government now is perceived as the only available "deep pocket."
  - US already direct or cross defendant in cases involved in 18,000 claims (see Chart 6).
  - Government uniformly successful in court thus far, but lack of any other "deep pocket" makes the government's litigation position vulnerable.
  - Loss of a single case will generate explosion of litigation against US.

IV. AGENT ORANGE

- Pending Agent Orange Compensation Bills -- Typical "foot-in-the-door" approaches advertised as "low-cost" or "procedural".
  - Daschle bill (H.R. 2017) requires compensation for virtually any Vietnam veteran suffering from three specific diseases purportedly related to Agent Orange exposure.
    - Because the medical evidence linking Agent Orange exposure to the three diseases is extremely tenuous, it will become nearly impossible to deny compensation for the myriad of other alleged Agent Orange diseases for which veterans are seeking compensation.
  - Cranston bill (S. 991) is purportedly "procedural," mandating rulemaking procedures to provide compensation for exposure to Agent Orange, low-level radiation and other "hazardous substances".
    - But Cranston bill heavily biases the ultimate result in favor of compensation by requiring formal rulemaking before allowing VA denial of claims, even as to a substance for which there is "insufficient medical or scientific evidence" to determine whether it caused a disease resulting in disability. The VA thus would be required to conduct hearings as to every conceivably toxic substance to which a veteran may have been exposed, and to reinstitute them as new "evidence" appears.
- Rapid Legislative Push Despite Comprehensive CDC Study Several Years Away
  - The two bills are moving forward even though initial results of the major epidemiological study by CDC still are several years off. But once Agent Orange disability compensation is provided, even if only for a handful of diseases, it may be impossible to bar compensation even if the study shows no long-term ill effects from Agent Orange exposure.

- Substantial Fiscal Exposure
  - Over 365,000 veterans are receiving Agent Orange medical care under a statutory standard that mandates such medical care even absent evidence linking the asserted disease to exposure.
  - Over 16,500 Agent Orange disability compensation claims already filed.
  - Since the VA presumes every Vietnam veteran to have been exposed absent evidence to the contrary, 2.5 million Vietnam veterans are potentially eligible for Agent Orange health care and disability compensation.
  - By making veterans' disability compensation available without firm evidence, the integrity of the entire compensation system is jeopordized. This endangers compensation for those war-injured veterans who most clearly deserve and need government support.

V. SUPERFUND

- Legislative Context
  - Currently Superfund is used for clean-up of hazardous sites -- not payment of compensation for personal injury. Compensation was a major issue when Superfund was enacted in 1980, but was eliminated in a Senate compromise.
  - Now facing strong legislative push for expansion of Superfund to serve as a pool to pay for tort law judgments and/or administrative compensation awards for persons exposed to hazardous substances and wastes off the workplace.
  - This will be major legislative issue with influential legislators, including Senate Committee Chairman Stafford, committed to pressing for sweeping legislative initiatives.
- Compensation Commission Report
  - As part of 1980 compromise, a Commission was established to study compensation. The Commission's recommendations adopted the worst of both worlds: an administrative compensation system with liberal evidentiary standards and generous benefits, as well as continued availability of traditional tort law.
- **Open-ended Fiscal Threat**
  - **Although its advocates now price Superfund compensation proposals at "only" a few billion dollars, the amounts at stake are literally open-ended and potentially enormous. Given the ambiguity of Superfund, compensation could be provided for virtually any environmental exposure, and not merely exposures directly related to waste disposal sites. Under the proposed compensation mechanisms substantial amounts will go to lawyers' fees -- creating a strong incentive for increased litigation. For example, one-half to two-thirds of asbestos industry pay-outs go to lawyers' fees and litigation expenses.**

VI. RADIATION

- o Renewed legislative efforts to provide compensation for low-level radiation exposure can be anticipated, fueled in part by anti-nuclear advocates, and in part by pork barrel politics.

  - o S. 921 (Hatch) provides a liberal litigation "remedy" against the United States, undermining many of the government's defenses in pending cases. The bill builds upon Section 7 of the Orphan Drug Act, which requires HHS to promulgate cancer risk assessments for persons exposed to low-level radiation.

  - o S. 11 (Cranston) requires the VA to conduct a major radiation epidemiological study. And, as noted, S. 991 (Cranston) calls for hearings, findings and broad discretion on the part of the VA Administrator to establish compensation awards.

- o The United States presently is involved in the downwind radiation litigations. One case alone, Allen v. United States, involves 1,269 claimants seeking $2 billion in damages. (See Chart 7.)

CHART 7

RADIATION LITIGATIONS INVOLVING UNITED STATES

Cases	Damage Claims
Allen v. United States (under advisement)	$2 billion
47 other pending suits in which the United States is a defendant	$827 million
31 pending suits against DOE contractor which the United States may have to indemnify for litigation losses	$4.78 billion

VII. OTHER TOXIC SUBSTANCES

- Exposure to other toxic substances on and off the workplace will continue to raise compensation issues. Other such toxic substances include dioxin, benzene, vinyl chloride, kepone, formaldehyde, PCB, PBB, as well as more common substances such as cotton dust (brown lung) and silica (white lung). Some of the most serious problem substances and exposure estimates are listed in the following table:

EXPOSURE ESTIMATES

SUBSTANCE	USE	WORKERS	RESIDENTS NEAR INDUSTRIAL OR WASTE SITES	LOW-LEVEL EXPOSURE
VINYL CHLORIDE	PLASTICS FLOOR TILES	MORE THAN 3.5 MILLION	4.6 MILLION	N/A
CARBON TETRACHLORIDE	INDUSTRIAL SOLVENT GRAIN FUMIGANT	3.4 MILLION	8 MILLION	41 MILLION
BENZENE	RAW CHEMICAL GASOLINE ADDITIVE	3 MILLION	N/A	OVER 75% OF POPULATION

BERYLLIUM AND COMPOUNDS	ELECTRICAL COMPONENTS	26 THOUSAND	721 THOUSAND	N/A

VIII. POLICY FORMULATION PROBLEMS

- In formulating its policy and strategy on issues relating to toxic torts and compensation, the Administration will have to deal with a host of problems.

  - Piecemeal Legislative Action: Over a hundred bills involving a dozen or more committees can be expected. With the exception of Superfund and Agent Orange, the Administration is less likely to be faced with majors battle than a series of legislative skirmishes.

  - Adverse Judicial Decisions: The federal government's litigation position has been weakened. Of primary concern are legal inroads by manufacturers who are being sued under product liability doctrines, and in turn are suing the United States for indemnification. Equally troublesome are recent judicial decisions holding the federal government liable for "negligent inspections." Under these cases, the United States potentially may be liable for injuries caused by private persons or companies in light of federal responsibility to assure appropriate health safety levels.

  - Political Volatility: This may be one of the most politically sensitive issues of the 1980's. The compensation issue has been described as the next major item on the environmental agenda. This volatility is exacerbated by the fact that most legislative initiatives tend to be dominated by unrepresentative "horror stories."

  - Lack of Coordination Among the Federal Agencies: The Administration's ability to respond to developments has been severely hampered by a lack of coordination among affected federal agencies. In addition, there are dozens of working groups and ongoing studies in the area that are uncoordinated and sometimes directly in conflict. The absence of an internal mechanism for obtaining broad Administration overview of toxic torts and compensation policies has resulted in reactive ad hoc policies in response to individual developments.

IX. TOXIC TORTS/COMPENSATION WORKING GROUP

- There is a need for an inter-agency Working Group to develop and recommend Administration strategy and policy, and to coordinate Administration strategy, policy and data collection among the federal agencies. Its general charter might consist of the following:
  - Identification of issues and problems involved.
  - Identification, analysis and monitoring of relevant legislation and hearings.
  - Identification, analysis and monitoring of relevant litigation.
  - Identification and analysis of relevant agency proceedings.
  - Policy development and recommendation of Administration strategy.
  - Policy coordination among the various Executive Branch agencies.
  - Service as an information clearinghouse within the Administration for issues involving toxic torts and compensation.

  - The activities of such a Working Group will need to be consistent with statutory responsibilities and mandates of affected agencies, and the Executive Order 12291 process. Within that context, the full participation in the Working Group of all affected federal agencies will be necessary if it is to be effective in forestalling inherently uncontrollable long-term fiscal exposure.

II. HISTORICAL CONTEXT: PARALLELS WITH BREAKDOWN OF POLICY PRINCIPLES DURING EXPLOSIVE 1960'S AND 1970'S GROWTH OF ENTITLEMENTS

o Current toxic substances compensation debate replicates the 1970 era debates over social welfare entitlements. Latter were created with low initial costs, understated long-term cost estimates, and no appreciation for expansionary pressures being set in motion. Today, we are paying for the consequences of "small" steps taken without understanding of long-term policy and fiscal implications.

o Explosive post-1970 growth of Social Security disability and Black Lung compensation -- two existing disability compensation systems directly relevant to the current debate over toxic substances compensation -- underscores long-range threat.

o Just as the 1970's welfare expansion built on the breakdown of conceptual barriers that limited government support to the truly needy, the toxic substances compensation movement is built on the breakdown of principles that link compensation to fault.

o This is a logical consequence of the relentless movement of tort law during the 70's towards absolute liability. This trend is reflected in increasingly stringent product liability doctrines that have converted manufacturers into societal insurers, as well as in the increasing demand for government-sponsored compensation systems.

HISTORICAL CONTEXT
(continued)

- The incipient movement towards federally financed toxic substances compensation embodies other parallels to 1970's social welfare entitlement expansions, including these:

  - Low initial cost estimates for various compensation schemes -- but once the "right" to government aid or rights of court action are established, the size and cost of programs become politically uncontrollable under constituency pressure for liberalization and expansion.

  - 1970's entitlement expansion preceded by a flood of reports and studies "documenting" the need for the new entitlements, often on the most tenuous of grounds. Dozens of similar studies of toxic torts and compensation are underway. Studies not supporting the case have limited impact, while those that find a need for compensation -- no matter how weak or suspect their conclusions -- serve as the foundation of media attention, hearings, initiatives, etc.

  - Resistence to "modest" first steps in the creation of major entitlement rights poses political difficulties of the highest order -- because it involves the political cost of resisting popular proposals now in order to avoid potentially heavy costs in the more distant future. Failure of earlier administrations to resist 1970's transfer payment expansions is now extremely costly. This Administration will face a similar test with toxic substances compensation -- as full costs will come on-stream in a major sense only during the next decade.

- Unfortunately, the Administration's ability to respond to the growing list of toxic substances compensation proposals is hampered by the lack of centralized policymaking. The Administration's response thus far has been fragmented, and largely determined by individual agencies' unique priorities. As a result, conflicting agency positions have undermined many of the Administration's legislative and litigation efforts.

III. ASBESTOS

- Asbestos Exposure
  - Approximately 13 to 15 million workers were exposed between 1940 and 1980.
  - Estimated total exposed population at 25 to 30 million.
  - Link to certain diseases, including lung cancer, has been definitively established.
- Litigation Status
  - Approximately 20,000 to 25,000 claims already filed.
  - 100,000 to 200,000 are expected in the next two to three decades (see Chart 4).
  - Industry litigation liability may be in excess of $30 billion (see Chart 5) -- probably more than industry assets and available insurance can cover.
- Fiscal Threat
  - Federal government now is perceived as the only available "deep pocket."
  - US already direct or cross defendant in cases involved in 18,000 claims (see Chart 6).
  - Government uniformly successful in court thus far, but lack of any other "deep pocket" makes the government's litigation position vulnerable.
  - Loss of a single case will generate explosion of litigation against US.

IV. AGENT ORANGE

- o Pending Agent Orange Compensation Bills -- Typical "foot-in-the-door" approaches advertised as "low-cost" or "procedural".

  - o Daschle bill (H.R. 2017) requires compensation for virtually any Vietnam veteran suffering from three specific diseases purportedly related to Agent Orange exposure.

    - o Because the medical evidence linking Agent Orange exposure to the three diseases is extremely tenuous, it will become nearly impossible to deny compensation for the myriad of other alleged Agent Orange diseases for which veterans are seeking compensation.

  - o Cranston bill (S. 991) is purportedly "procedural," mandating rulemaking procedures to provide compensation for exposure to Agent Orange, low-level radiation and other "hazardous substances".

    - o But Cranston bill heavily biases the ultimate result in favor of compensation by requiring formal rulemaking before allowing VA denial of claims, even as to a substance for which there is "insufficient medical or scientific evidence" to determine whether it caused a disease resulting in disability. The VA thus would be required to conduct hearings as to every conceivably toxic substance to which a veteran may have been exposed, and to reinstitute them as new "evidence" appears.

- o Rapid Legislative Push Despite Comprehensive CDC Study Several Years Away

  - o The two bills are moving forward even though initial results of the major epidemiological study by CDC still are several years off. But once Agent Orange disability compensation is provided, even if only for a handful of diseases, it may be impossible to bar compensation even if the study shows no long-term ill effects from Agent Orange exposure.

- Substantial Fiscal Exposure
  - Over 365,000 veterans are receiving Agent Orange medical care under a statutory standard that mandates such medical care even absent evidence linking the asserted disease to exposure.
  - Over 16,500 Agent Orange disability compensation claims already filed.
  - Since the VA presumes every Vietnam veteran to have been exposed absent evidence to the contrary, 2.5 million Vietnam veterans are potentially eligible for Agent Orange health care and disability compensation.
  - By making veterans' disability compensation available without firm evidence, the integrity of the entire compensation system is jeopordized. This endangers compensation for those war-injured veterans who most clearly deserve and need government support.

V. SUPERFUND

- Legislative Context
    - Currently Superfund is used for clean-up of hazardous sites -- not payment of compensation for personal injury. Compensation was a major issue when Superfund was enacted in 1980, but was eliminated in a Senate compromise.
    - Now facing strong legislative push for expansion of Superfund to serve as a pool to pay for tort law judgments and/or administrative compensation awards for persons exposed to hazardous substances and wastes off the workplace.
    - This will be major legislative issue with influential legislators, including Senate Committee Chairman Stafford, committed to pressing for sweeping legislative initiatives.
- Compensation Commission Report
    - As part of 1980 compromise, a Commission was established to study compensation. The Commission's recommendations adopted the worst of both worlds: an administrative compensation system with liberal evidentiary standards and generous benefits, as well as continued availability of traditional tort law.
- Open-ended Fiscal Threat
    - Although its advocates now price Superfund compensation proposals at "only" a few billion dollars, the amounts at stake are literally open-ended and potentially enormous. Given the ambiguity of Superfund, compensation could be provided for virtually any environmental exposure, and not merely exposures directly related to waste disposal sites. Under the proposed compensation mechanisms substantial amounts will go to lawyers' fees -- creating a strong incentive for increased litigation. For example, one-half to two-thirds of asbestos industry pay-outs go to lawyers' fees and litigation expenses.

VI. RADIATION

- Renewed legislative efforts to provide compensation for low-level radiation exposure can be anticipated, fueled in part by anti-nuclear advocates, and in part by pork barrel politics.

    - S. 921 (Hatch) provides a liberal litigation "remedy" against the United States, undermining many of the government's defenses in pending cases. The bill builds upon Section 7 of the Orphan Drug Act, which requires HHS to promulgate cancer risk assessments for persons exposed to low-level radiation.

    - S. 11 (Cranston) requires the VA to conduct a major radiation epidemiological study. And, as noted, S. 991 (Cranston) calls for hearings, findings and broad discretion on the part of the VA Administrator to establish compensation awards.

- The United States presently is involved in the downwind radiation litigations. One case alone, Allen v. United States, involves 1,269 claimants seeking $2 billion in damages. (See Chart 7.)

CHART 7

RADIATION LITIGATIONS INVOLVING UNITED STATES

Cases	Damage Claims
Allen v. United States (under advisement)	$2 billion
47 other pending suits in which the United States is a defendant	$827 million
31 pending suits against DOE contractor which the United States may have to indemnify for litigation losses	$4.78 billion

VII. OTHER TOXIC SUBSTANCES

- o Exposure to other toxic substances on and off the workplace will continue to raise compensation issues. Other such toxic substances include dioxin, benzene, vinyl chloride, kepone, formaldehyde, PCB, PBB, as well as more common substances such as cotton dust (brown lung) and silica (white lung). Some of the most serious problem substances and exposure estimates are listed in the following table:

EXPOSURE ESTIMATES

SUBSTANCE	USE	WORKERS	RESIDENTS NEAR INDUSTRIAL OR WASTE SITES	LOW LEVEL EXPOSURE
VINYL CHLORIDE	PLASTICS FLOOR TILES	MORE THAN 3.6 MILLION	4.6 MILLION	N/A
CARBON TETRACHLORIDE	INDUSTRIAL SOLVENT GRAIN FUMIGANT	3.4 MILLION	8 MILLION	41 MILLION
BENZENE	RAW CHEMICAL GASOLINE ADDITIVE	3 MILLION	N/A	OVER 75% OF POPULATION
FORMALDEHYDE	RESINS TEXTILES COSMETICS INSULATION	UP TO 2.8 MILLION	27.7 MILLION	N/A
CHROMIUM AND COMPOUNDS	ALLOYS PIGMENTS	2.5 MILLION	N/A	ENTIRE POPULATION
1,2 – DICHLOROETHANE	CHEMICAL INTERMEDIATE LEADED FUEL GRAIN FUMIGANT	UP TO 2 MILLION	N/A	ENTIRE POPULATION
POLYCHLORINATED BIPHENYLS (PCBs)	ELECTRICAL COOLING LIQUIDS	N/A	12 MILLION	WIDESPREAD CONTAMINATION
DIOXIN (TCDD)	PESTICIDE CONTAMINANT	N/A	7.7 MILLION	169 MILLION
NICKEL AND COMPOUNDS	ALLOYS ELECTRONICS EDIBLE OILS COINS	709 THOUSAND	720 THOUSAND	ENTIRE POPULATION
ARSENIC AND COMPOUNDS	PESTICIDES PAINTS HIDE PRESERVATION	545 THOUSAND	N/A	ENTIRE POPULATION
CHLOROFORM	SOLVENT DRUGS PESTICIDES	360 THOUSAND	N/A	N/A
CADMIUM AND COMPOUNDS	ELECTROPLATING BATTERIES FUNGICIDES	300 THOUSAND	N/A	SMOKERS
LEAD COMPOUNDS	PAINT HAIR DYES PLASTICS	UP TO 278 THOUSAND	N/A	N/A
ACRYLONITRILE	CHEMICAL INTERMEDIATE	278 THOUSAND	N/A	N/A
1,2 DIBROMOETHANE	LEADED GASOLINE SOLVENT PESTICIDES	UP TO 218 THOUSAND	N/A	650 THOUSAND GAS STATION ATTENDANTS
BERYLLIUM AND COMPOUNDS	ELECTRICAL COMPONENTS	26 THOUSAND	721 THOUSAND	N/A

VIII. POLICY FORMULATION PROBLEMS

- In formulating its policy and strategy on issues relating to toxic torts and compensation, the Administration will have to deal with a host of problems.
  - Piecemeal Legislative Action: Over a hundred bills involving a dozen or more committees can be expected. With the exception of Superfund and Agent Orange, the Administration is less likely to be faced with majors battle than a series of legislative skirmishes.
  - Adverse Judicial Decisions: The federal government's litigation position has been weakened. Of primary concern are legal inroads by manufacturers who are being sued under product liability doctrines, and in turn are suing the United States for indemnification. Equally troublesome are recent judicial decisions holding the federal government liable for "negligent inspections." Under these cases, the United States potentially may be liable for injuries caused by private persons or companies in light of federal responsibility to assure appropriate health safety levels.
  - Political Volatility: This may be one of the most politically sensitive issues of the 1980's. The compensation issue has been described as the next major item on the environmental agenda. This volatility is exacerbated by the fact that most legislative initiatives tend to be dominated by unrepresentative "horror stories."
  - Lack of Coordination Among the Federal Agencies: The Administration's ability to respond to developments has been severely hampered by a lack of coordination among affected federal agencies. In addition, there are dozens of working groups and ongoing studies in the area that are uncoordinated and sometimes directly in conflict. The absence of an internal mechanism for obtaining broad Administration overview of toxic torts and compensation policies has resulted in reactive ad hoc policies in response to individual developments.

IX. TOXIC TORTS/COMPENSATION WORKING GROUP

- There is a need for an inter-agency Working Group to develop and recommend Administration strategy and policy, and to coordinate Administration strategy, policy and data collection among the federal agencies. Its general charter might consist of the following:

  - Identification of issues and problems involved.
  - Identification, analysis and monitoring of relevant legislation and hearings.
  - Identification, analysis and monitoring of relevant litigation.
  - Identification and analysis of relevant agency proceedings.
  - Policy development and recommendation of Administration strategy.
  - Policy coordination among the various Executive Branch agencies.
  - Service as an information clearinghouse within the Administration for issues involving toxic torts and compensation.

  - The activities of such a Working Group will need to be consistent with statutory responsibilities and mandates of affected agencies, and the Executive Order 12291 process. Within that context, the full participation in the Working Group of all affected federal agencies will be necessary if it is to be effective in forestalling inherently uncontrollable long-term fiscal exposure.

Fourth Recommendation: Tier One -- Rebuttable Presumptions

The Study Group recommends that legislation establishing the compensation system provide for two kinds of rebuttable presumptions; the first extending merely to the issue of causation, the second going beyond proof of causation into such issues as the nature and extent of the disease or injury resulting from exposure to hazardous wastes. The first set of presumptions would be based on the proof of several elements which then give rise to rebuttable presumptions of causation. The second set of presumptions should be based on the proof of the same elements as well as on previously prepared and adopted "Toxic Substance Documents" based on scientific data that link the exposure to certain designated hazardous wastes to their known effects in causing injury or disease. The second set of presumptions would also meet additional elements of proof.

In both instances, the same basic showing should be made. If the claimant in an administrative compensation proceeding proves:

1) that the source involved in the claim was engaged at the time of exposure in the production, transportation or disposal of hazardous wastes; and

2) that the claimant was exposed to such hazardous waste by proximity, contact, ingestion, inhalation, or by some other form of exposure; and

3) that the claimant suffered death or the kind of injury or disease which is known to result from such exposure then the following rebuttable presumptions should arise: (a) that the exposure to the hazardous waste generated, transported or disposed of, by or in the source, contributed to the death, injury or disease of the claimant; and (b) that the source by or in which such hazardous wastes were generated, transported or disposed of was responsible for the claimant's exposure and for the resulting death, injury or disease.

In the rebuttable presumption set forth above, to show that death or the kind of injury or disease suffered by the claimant is "known to result" from such exposure, a Toxic Substance Document (as described infra) shall be relied on, if such a document has been prepared for the specific hazardour substance or waste.

In addition to these basic presumptions, additional presumptions may apply if the federal agency authorized to administer the compensation system (which will be operated by the states subject to federal statutory requirements), has issued documents to provide evidentiary data showing that specific hazardous substances or wastes cause specific diseases or illnesses.

Such documents, here referred to as Toxic Substance Documents should be prepared by the agency on the basis of scientific data, including its accumulated information on particular hazardous wastes or substances, collected in connection with the administration of the Clean Air Act (CAA), the Clean Water Act (CWA), Federal Insecticide, Fungicide and Rodenticide Act (FIFRA), Resource Conservation and Recovery Act (RCRA), Toxic Substances Control Act (TOSCA), Comprehensive Environmental Response, Compensation and Liability Act (CERCLA), as well as the Occupational Safety and Health Act (OSHA), and on the basis of evidence collected in connection with past or pending cases. The Agency should produce Toxic Substance Documents for some of the best known 20 or 30 hazardous substances on which data are available, including dioxin, chromium, kepone and PCB, and that the Agency could add Toxic Substance Documents from time to time for additional hazardous substances or wastes as their danger becomes more evident, and as data become available. A Toxic Substance Document should be adopted following the publication of the proposed document, together with all supporting data and materials, set forth in full or by reference to published scientific papers, and should be adopted and promulgated following an opportunity for comment.[20] An appropriate rulemaking procedure should be followed to assure the scientific accuracy of the results.

For each hazardous substance or waste, the applicable Toxic Substance Document should set forth the following:

TSD's

1) Elements of exposure including

a) nature of exposure, such as skin contact, ingestion, inhalation;

b) level of exposure, stated, where appropriate, in terms of a range of exposure levels expressive of the intensity of the exposure measured, when appropriate, by ambient concentration;

c) duration of exposure, expressed, where appropriate, in terms of a range of time periods of exposure.

2) The disease or diseases resulting from exposure, including data on:

a) the etiology of the disease, as related to nature, level and duration of exposure;

b) the symptoms of the disease and the available methods for its diagnosis, including direct observation, clinical and other diagnostic tests;

c) the latency period, if any, of the disease, as related to the nature, level and duration of exposure;

d) the prognosis for the disease, including the anticipated course of the disease, its treatment and its impact or duration in terms of disability, reduction or loss of function, and reduction of life expectancy;

e) other impacts, including mutagenicity, teratogenicity and carcinogenicity in the progeny of the person exposed.

(3) Other parameters relating to exposure, etiology and the course and consequences of the disease, including aspects of susceptibility and their variation depending on such factors as age and sex and such other conditions as pregnancy, or disease from causes other than exposure to the hazardous wastes or substances involved.

When a Presumption Document has been prepared for a particular hazardous waste, upon proof of exposure, source and proof of the occurrence of death or disease -- as in the case of the rebuttable presumption of causation --additional rebuttable presumptions shall apply as to matters of exposure, etiology, prognosis, nature and duration of the disease, insofar as these matters are covered in the Toxic Substance Document and insofar as they may be relevant or material to the claim.

Discussion

1. The Recommendations

A majority of the Study Group was in agreement on the need for reliance on rebuttable presumptions on the First Tier, as part of the compensation remedy. The Study Group was in general agreement that the rebuttable presumptions here recommended for the Tier One compensation remedy are inappropriate for the Tier Two plenary tort action. Several members of the Group expressed strong doubts on the desirability of statutory presumptions, and some members suggested

REPORT ON THE FEASIBILITY OF ORGANIZING A STUDY TO ASSESS THE POTENTIAL HEALTH HAZARDS OF WASTE DISPOSAL SITES WITHIN THE UNITED STATES

Submitted by

UNIVERSITIES ASSOCIATED FOR RESEARCH AND EDUCATION
IN PATHOLOGY, INC.

June 22, 1983

UAREP, with technical assistance from the Life Sciences Research Office (LSRO) of the Federation of American Societies for Experimental Biology (FASEB), has completed the feasibility study requested by CMA. A detailed report, presented in two parts, is submitted herewith. Part I describes the feasibility study, and Part II describes the proposed comprehensive review. We have concluded that within the time constraint of 10 months it is feasible to carry out a review of existing data and prepare a report covering the following general areas:

1. Prepare a list of the chemicals most likely to occur in a majority of waste disposal sites and which are most likely to create health hazards.

2. Identify the acute and, to a limited extent, the long-term toxic effects likely to result from human exposures to such chemicals. This would largely be based on published data in the peer review literature and make use of certain secondary sources of material available from industry as well as state and federal agencies.

3. Estimate the levels and duration of exposure to these chemicals at or above which toxic effects might be expected.

4. Identify those clinical and laboratory investigations which are likely to be most useful in detecting health effects in exposed populations and the epidemiological techniques to be utilized in so doing.

5. Develop scientific criteria for identifying immediate health hazards requiring urgent investigation or attention.

In carrying out such a review UAREP proposes to utilize a blue-ribbon panel of senior scientists and two special task forces assisted by professional and support staff.

We believe the review can be completed in 8 to 10 months, that adequate data is available and that the scientific and professional expertise necessary for organization of the panels, task forces, and staff can be obtained.

I. REPORT OF UAREP FEASIBILITY STUDY GROUP TO CMA ON THE POSSIBILITY OF ORGANIZING A STUDY TO ASSESS THE POTENTIAL HEALTH HAZARDS OF WASTE DISPOSAL SITES WITHIN THE UNITED STATES

A. INTRODUCTION

Public concern over the potential health hazards of waste disposal throughout the United States has reached a high level. The U.S. Congress and several state legislatures have enacted laws aimed at identifying hazardous sites and taking remedial action. Several thousand sites have been identified and the U.S. Environmental Protection Agency has designated that over 400 require "priority attention".

The problem of hazardous wastes has been the subject of considerable media coverage but the scientific documentation is more limited. Among the scientific publications are "Assessment of Health Effects at Chemical Disposal Sites" (Life Science and Public Policy Program of the Rockefeller University, 1981), and "Management of Hazardous Industrial Wastes: Research and Development Needs" (National Research Council, 1983). The former emphasizes the difficulties of making risk assessments in view of the complications involved in evaluating exposures. The latter reviews and makes certain recommendations regarding waste disposal and also recommends that "both public and environmental risks should be covered in a manner that allows comparison with existing risks that are acceptable to society," and that "an educational program be established to provide the public and industry with soundly based information on the options and risks that are acceptable to society" (page 14). The technical and practical problems of health effects on an individual basis are outlined in the study of the Love Canal (EPA, 1980) and, more recently, Heath (1983) has examined the epidemiology difficulties.

Whereas the National Research Council study does provide a certain consensus regarding the generic and practical issues involved in waste management, the nature and extent of health problems associated with waste disposal sites are much more controversial. Accordingly, though a small number of sites have been the subject of intensive study, the relevance and extent of these findings as related to the problem on a national scale is very uncertain and requires more intensive investigation.

In view of these facts and the delay in carrying out adequate in-depth studies of health effects on an individual waste disposal site basis and the need to obtain more factual information of potential health effects, the Chemical Manufacturers Association (CMA) concluded that it would be of value to all concerned if a group of knowledgeable and prestigious scientists could examine available scientific data and reach an interim conclusion regarding the nature and extent of health hazards which may exist at waste disposal sites as a basis for interim strategy and policy. Further, such a group would outline the scientific criteria for identifying potentially hazardous sites and indicate the methodology of investigation.

In March 1983, CMA entered into an agreement with Universities Associated for Research and Education in Pathology, Inc. (UAREP) to carry out a Feasibility Study to learn how and whether such aims might be achieved through the organization of a scientific review based on the expertise of the academic community.

B. SCOPE OF THE FEASIBILITY STUDY

A small group was set up within UAREP and the Life Sciences Research Office (LSRO) of the Federation of American Societies for Experimental Biology (FASEB) to initiate the feasibility study. The goals of the group were (1) to determine what the aims and objectives of such a scientific study would be, i.e., health effects, exposures, etc.; (2) to determine how such a study would be organized and conducted; (3) to identify sources of information relative to (1) and (2) above; and (4) if possible, to identify what additional studies should be considered, if necessary. The group took into consideration the following areas as pertinent to the objectives of such a scientific review:

1. Information on i) the criteria of health effects to be used in evaluating endpoints of hazards, ii) the methodology of determining how such causal associations are to be determined, and iii) the extent and limitations of the universe of substances likely to be associated with waste disposal sites and their potential exposures for humans.

2. Identification of sources of data, as well as their relevance and potential significance in assessing health effects in waste disposal sites.

3. Information as to the availability of appropriate scientific experts in academia who might be available to participate in carrying out the study.

4. Information relevant to the organization of the interim study.

Initially, the Feasibility Study Group identified a number of parameters that might be addressed during the scientific review, including:

1. Determination of what inferences could be drawn from knowledge of hazardous chemical substances present in waste disposal sites and the probability of human exposures in relation to all types of health effects.

2. Identification of what inferences can be drawn regarding the effects of such substances based on other studies on humans or on animals, i.e., in environmental, occupational, or other settings, and included reports from existing waste disposal site studies. This also included the problem of assessing the limitations of epidemiology and other techniques in evaluating the effects of low level exposures to potential agents.

3. The possibility of carrying out preliminary correlation surveys based on i) known waste disposal sites, ii) studies on states known to have a high degree of environmental pollution, and iii) correlation studies based on general investigations in the U.S. in terms of pollution whether urban or rural, and involving air or water.

4. The possibility of the interim group establishing scientific criteria for identifying the existence of imminent health hazards in relation to chemical waste disposal sites and what would be the criteria or endpoints in terms of clinical and pathological data.

5. The possibility of the study group indicating further areas as requiring investigation in depth for the purpose of making the final reports more meaningful.

These various points were examined and an appropriate planning document prepared and circulated to a number of senior scientists as a background for discussion.

A number of experts representative of epidemiology, environmental waste disposal, toxicology, experimental biology, and biostatistics were approached (see Appendix I). In addition, a number of individuals in the field of experimental pathology and two representatives of environmental organizations were contacted. A considerable amount of effort was expended on contacting individuals within the Environmental Protection Agency (EPA) to determine the data and material available in its archives. The CMA advised UAREP/LSRO on contacts within the chemical industry; member companies of CMA prepared and submitted material for consideration by the Feasibility Study Group. Some individuals prepared reports and submitted them to UAREP/LSRO. Others were visited by members of the Feasibility Study Group or visited UAREP in Bethesda.

C. VIEWS OF EXPERTS

As anticipated, there was a wide range of opinions regarding the objectives and organization of any study relative to waste disposal sites. All were agreed on the inherent difficulties involved, but differed as to their importance in relation to an overall review. Some emphasized that if the problem was to be investigated, it should be done well or not at all. The majority agreed that, by far, the best way to investigate the overall problem was to carry out systematic examinations of individual sites. However, some experts also recognized the logistical difficulties associated with doing so in the immediate future, and concluded that some form of interim scientific evaluation of the extent and nature of the health problem was essential to provide some basis for rational public health policies and strategies in the next few years. For example, the Centers for Disease Control (CDC) have investigated only five sites in depth, although there is a considerable amount of material available on an additional twenty. All experts emphasized the fundamental importance of determining human exposures in relation to waste disposal sites, but none could offer exact guidance as to how this might be accomplished except through study of individual sites.

The point was raised by a number of individuals that in the past, few human health effects have been demonstrated to be caused by waste disposal sites and, therefore, it is probable that despite considerable efforts, little additional information may be obtained in future efforts of this type. If true, such a finding is clearly of importance in terms of future public health strategy and control of waste disposal sites since it suggests that more emphasis should be placed on methods of diminishing waste disposal, as done by the Japanese, than on the investigation and clean-up of existing sites. Many consultants indicated their doubt that the public will readily accept such a conclusion in view of preconceptions as to health hazards which have developed over the last several years and because of extensive media coverage of "crises". These aspects undergird the importance of ensuring the credibility of any study which carries out an overall investigation of this problem.

D. IDENTIFICATION OF POTENTIAL DATA SOURCES

The Feasibility Study Group discussed sources of data with the consultants and carried out preliminary surveys of the general literature. UAREP/LSRO staff members reviewed data retrieved from computerized literature services (Medline, Cancerline, Toxline, and Enviroline). They also reviewed such publications as the monograph series of the International Agency for Research on Cancer, and the Environmental Health Criteria documents of the World Health Organization on toxic hazards. In addition, a number of key articles were reviewed relative to the availability of specific material regarding waste disposal sites (*see* Appendix II). In brief, it can be stated that the amount of material available in the literature with respect to specific studies on hazardous waste disposal sites is very small. On the other hand, there are considerable data available regarding individual chemicals and their health effects based on a variety of studies including animal toxicology and epidemiology studies of occupational and other populations which might be of use for drawing inferences as to possible health effects.

There is a large amount of material available in the CDC on the potential health effects of waste disposal sites. Whereas some of it has been published in the general literature, the greater part is available as internal technical reports. However, the CDC staff indicated that this material would be made available to UAREP, and they would be pleased to collaborate directly with the UAREP study group in evaluating and identifying data pertinent to the overall problem. The experts at CDC were of the opinion that only waste disposal sites at Love Canal, New York; Triana, Alabama; Woburn, Massachusetts; and Times Beach, Missouri had been investigated adequately.

Key EPA personnel were contacted but little additional information seemed to be readily available regarding the problem, despite the fact that other experts indicated to the Feasibility Group that EPA has the best data on exposures. Several EPA contacts indicated that the desired information might be obtained from the CDC in Atlanta, but the CDC stated they had exposure data only for sites in which they had carried out some initial health investigations. CDC referred UAREP back to EPA. In conclusion, it proved impossible to identify who in EPA had such material; it was decided to await further approaches until after the organization of a review group.

Industry made material available to UAREP regarding exposures to suspected problem chemicals in the work place. A number of reprints and drafts of studies underway were made available to the Feasibility Study Group which were clearly pertinent and valuable in drawing inferences (see Appendix II). Key reference material is identified in Appendix III. In some cases these documents can be amplified by the literature in peer review journals. These data will be valuable and pertinent relative to information on the potential effects at specific exposure levels, but such data again raise the perennial question of how to deal with the effects of exposure at very low levels which would be fundamental to much of the assessment of the study group.

Preliminary contacts were made in the United Kingdom, and it would appear that within the European Common Market a considerable amount of data have been collected relative to hazardous waste disposal. Apparently, studies have also been carried out on potential health effects in some areas, but relatively little has been published. It is intended to investigate in further depth what material is available later this year, but preliminary investigations indicate that a number of individuals in Europe will be eager to collaborate in this context.

In conclusion, there appears to be less published data regarding the specific effects of waste disposal sites than had been originally anticipated. Although it is clear that much pertinent information is present in archives of various sorts, it will require a concerted effort to obtain and analyze this material. On the other hand, a considerable amount of published literature is available which contains important material on which inferences may be drawn by appropriate experts regarding potential health effects. The weakest area appears to be in relation to potential exposure levels. In this context, preliminary correlation studies may be of value. The Feasibility Study Group further explored what already had been done in this context.

1. Studies of Individual Waste Sites

While all agreed that a comprehensive study of individual waste disposal sites would be the most satisfactory rational method in identifying or excluding potential health effects, to do so would require extensive resources in manpower and expertise and a considerable period of time to implement. Clearly, it is exceedingly difficult to evaluate the potential danger of a waste disposal site unless accurate information, not only on the chemicals present but also on the probable degree of human exposure, is available. This suggests that for the study it will be necessary to draw up some general guidelines as to possible approaches. It will be highly desirable to explore what material is available within CDC in the form of internal reports in this context. CDC had considered but dropped the possibility of using certain chemicals as indicators of pollution. These CDC reports cover the PCB problem in the North Hollywood dump in Tennessee; the PBB problem in Michigan; the asbestos problem in Globe, Arizona; arsenic at Woburn, Massachusetts; and in a mixed deposit at Tar Creek, Kansas and Oklahoma. The reason many reports have not been published is that the data are essentially negative, far from complete and, therefore, "uninteresting". Thus, if relatively little evidence of exposure was found in a population group, no further action relative to health effects was undertaken. It would appear essential to explore further the importance of these negative findings as it may be fundamental to the objectives of the interim study to determine what are the conditions in which exposures are likely to occur and the period that may elapse before a site begins to break down and become a hazard. This will require further contact with appropriate experts in that area.

2. State Correlation Studies

Drs. R. S. Levine and D. Chitwood of the Department of Epidemiology and Public Health at the University of Miami prepared an "Analysis of Existing Data Pertaining to Potential Health Problems from Hazardous Wastes in Florida" in April 1983, acting under Prof. J. Davies. This was a rapid survey of the state of Florida covering areas of waste disposal sites and associated health indices in relation to such deposits. In general, no health effects were found in most areas of the state that could be definitively correlated with the EPA designated sites, although in some sites, there was a trend toward lower indices of health. However, in other areas of the state where pollution was known to be considerable, no health effects were evident. In fact, these often were the most healthful areas relative to the rest of the state and the U.S. as a whole. No definitive conclusions could be drawn on the health effects of such sites. On the other hand, Davies believes that such an approach can demonstrate that, while a health hazard due to a waste disposal site cannot be completely excluded, such studies can provide most useful data as to the probable existence and extent of the health problem. Interestingly enough, this Florida study indicated that an immense amount of material relative to existing sites had already been collected and was present in the State Department of Health. This suggests that in planning and investigating exposures, it may be desirable to use these sources in addition to EPA or CDC. The Miami workers were convinced, therefore, that this approach did provide data of relevance and should be tried out in several other states. They estimated that each such study could be carried out at a cost of approximately $100,000 within a three month frame utilizing the resources of local universities and departments of health. However, these costs may be unrealistically low because for the Florida study personnel, facilities, computers, and related equipment and materials were already in place.

The Feasibility Study Group felt that this approach should be explored further during the review as a potential source of data in carrying out future follow-up investigations to place some limits on the probable extent of the hazard.

E. FEASIBILITY STUDY RESULTS

1. Availability of Data

There is extensive literature available regarding the toxicology of many chemicals, but specific information relating to the amount of each chemical in individual waste disposal sites, the degree of population exposures, and the potential hazards involved are very limited. Thus, unless specific assumptions are made, the problem theoretically can be so huge as to defy analysis. Accordingly, it is estimated that the study will need to confine its review to a limited universe of chemicals, to drawing specific inferences that might be pertinent to the overall problem, and to defining and justifying such assumptions on a scientific basis.

2. Availability of Expert Consultants and Staff

Conversations with a number of experts disclosed a broad interest in toxic waste disposal problems and a willingness to participate in a scientific approach to solving these problems. Recruitment should not present a major problem although some desirable candidates will be unavailable due to other commitments or serious conflicts of interest.

A preliminary list of potential consultants is presented in Appendix IV. This list will be expanded as necessary in the course of the study, especially after the first meeting of the Executive Scientific Panel.

Based on previous experience, it was decided that resolution of problems such as conflict of interest and willingness to testify should not be attempted during the feasibility study but, rather, should await authorization to proceed with the comprehensive review.

F. CONCLUSIONS

1. The Feasibility Study Group concluded that it is both desirable and feasible to carry out a comprehensive review to evaluate the substantial body of available data for the purpose of permitting an interim conclusion as to the nature of the health problems likely to be associated with waste disposal sites. A detailed presentation of the Feasibility Study Group recommendations on the organization and implementation of the comprehensive review study follows (Part II). Such a study would have the following objectives:

i) Preparation of a universe of chemicals most likely to occur in waste disposal sites and which are most likely to create health hazards.

ii) The levels and duration of exposure to these chemicals above which toxic effects might be expected would probably have to depend largely on inferences. Thus, the perennial question of the presence or absence of low exposure level effects would require emphasis and standard methodological approaches. However, a considerable amount of material is available regarding water and air pollution within the U.S. which can be used in determining such possibilities. It will not be possible, however, to utilize all the material available within EPA and other institutions.

iii) Identification of the acute and, to a more limited extent, the long-term toxic effects likely to result from human exposures to such chemicals, and whether they are real or imagined. This review would be based principally on published data in the peer review literature. It would make considerable use of secondary sources of material in view of the great difficulty of evaluating the vast amount of primary and raw material in EPA or state archives, unless the latter had been adequately analyzed.

iv) Identification of those clinical and laboratory investigations which are likely to be most useful in detecting health effects in exposed populations and the epidemiological techniques to be utilized in so doing.

v) Development of scientific criteria for identifying an immediate health hazard requiring urgent investigation or attention.

A comprehensive review is considered desirable and feasible because it would be comparatively inexpensive in terms of money and manpower. While it will add relatively nothing new to the universal literature, it will provide a unique source of evaluated data for scientists and the public regarding the potential health hazards and scientific issues associated with investigating waste disposal sites. It will provide a mechanism whereby the scientific community can be directly involved in investigating such issues and correcting the misconceptions that are widely held by the public. It will identify problems that are likely to occur frequently and thus involve academia in a search for scientific rational solutions. This may be pertinent to the further development of more intensive studies on an individual waste disposal site basis which may be necessary over the next decade.

Such a review might be more credible if it had multiple sponsors and if it were perceived as an interim measure to be followed up by additional studies.

2. The Feasibility Study Group concluded that as the proposed review is being completed, it would be desirable to follow up with studies aimed at compiling and analyzing raw data in the files of EPA, CDC, and various states agencies, carrying out in other states procedures modeled after the Florida study, analyzing the NHANES II data bank and results of the Health Interview Surveys conducted by NCHS to develop baseline health values, and testing the validity of the criteria developed in the review in a limited number of specific toxic waste disposal sites.

Such follow-up studies would require participation of various agencies and organizations and should also be funded from a number of sources probably including government, industry, and private philanthropy. The follow-up studies would also require wider and more extensive involvement of the academic community in developing correlation studies and utilizing data from all sources, as well as more active involvement and cooperation between the academic community and CDC, as well as other government laboratories. In addition, follow-up studies would enhance the probability of producing new data and providing better baselines for developing new scientific and technological criteria for hazardous waste disposal.

The only major disadvantage associated with follow-up studies is the potential cost and the necessity for developing considerable manpower and resources in academia. On the other hand, these costs are likely to be relatively modest in the context of the vast expenses incurred in cleaning up waste disposal sites if this is not done on a rational basis.

II. FEASIBILITY STUDY GROUP RECOMMENDATIONS ON THE ORGANIZATION AND IMPLEMENTATION OF THE COMPREHENSIVE REVIEW STUDY

A. OBJECTIVES:

1. To prepare a list of the universe of chemicals associated with waste disposal sites which could prove hazardous to man as the result of excessive exposure. Identify, if possible, the levels of human exposures likely to occur in association with waste disposal sites.

2. To define the probable health effects likely to occur in association with waste disposal sites and classify these according to their nature, real or imagined, acute, subacute, chronic, or carcinogenic. This is to be based on inferences from the available studies within the literature and inferences drawn from occupational, animal toxicology, and other sources.

3. To identify the clinical and laboratory end results that should be utilized in investigating such problems, and the epidemiological criteria necessary to establish causal relationships. Special emphasis should be given to the evaluation of negative data in relation to low level exposures.

4. To identify the scientific criteria for describing a specific or individual waste disposal site as representing an imminent health hazard.

5. To decide to what extent these conclusions (#1-4) provide a basis for identifying which follow-up studies may be carried out.

B. IDENTIFICATION OF PROBLEM CHEMICALS AND THEIR EVALUATION

Crucial to the development of the study will be the establishment of guideline criteria for identifying the universe of substances in waste sites and for establishing causal associations between exposures and potential human health effects.

1. Universe of Substances and Waste Sites

For logistical reasons, the list of hazardous chemicals must be defined and limited but, at the same time, hazards of perceived potential major significance must not be excluded. Identification of such chemicals and their exposure levels will be fundamental to the success of the study because, above all, it will be necessary to review the effects of probable human exposures likely to occur, or to have occurred, in relation to hazardous waste disposal sites as a basis for any epidemiological approach.

In attempting to analyze the universe of hazardous substances, the following lists of chemicals have been examined during the Feasibility Study:

i) Chemicals identified in the Superfund Priority Sites list of 418 hazardous waste disposal sites. The list of chemicals was prepared by Dr. Blaine McKusick of du Pont.

ii) A list of chemicals provided by CMA and designated by six major chemical-producing companies as those considered to be the 20 most likely to cause risks or public perception of risk. Each company had prepared its own list of 20 problem chemicals. A few chemicals received five to six votes, but most received two or three, indicating that the interests of the six companies are not necessarily similar. However, the final list of 20 represents a consensus of the six chemical producers.

iii) A list of chemicals prepared for the State of California and published in Chemical and Engineering News 1982.

iv) EPA list of relative carcinogenic potencies among 53 chemicals evaluated by the Carcinogen Assessment Group (dated April 5, 1983.)

v) Other sources of material relating to general or local environmental pollution, such as the Love Canal list and lists provided by several consultants.

It is interesting to note that there is a certain degree of overlap among the chemicals on each of the lists mentioned above.

2. Evaluation of Exposures

Estimation of exposures are recognized to vary widely and, until now, no satisfactory methods of calculating these have apparently been developed. Thus, each waste disposal site must be investigated according to a highly systematic plan. The possibility, however, that an appropriate group will be able to provide guidelines for the development of appropriate models as to those chemicals most likely to pose a danger according to the construction, location and nature of a deposit will receive careful attention. Some attempt must be made to distinguish between waste disposal sites that are well constructed and likely to exist for a prolonged period, and those where there is evidence already of immediate breakdown and release. It is recognized that while air and direct exposures may occur, they are unlikely to present an important hazard and that greatest concern relates to potential water contamination and, possibly indirectly, through diet resulting from contamination of local vegetation.

Most important, the overall significance of small waste disposal sites must be examined. For example, these were believed to be the greatest problem in Florida. It will be necessary, therefore, to explore all these aspects of the problem and to ensure that the Executive Panel and two Task Forces contain experts who have had experience in movement of substances from sites. Thus, evidence in this area will depend on i) material from sites which have already been examined, ii) literature reports in this and other countries, iii) the availability of further material of the type that was obtained in Florida from local resources, and iv) other sources. It may be possible that, after reorganization, EPA may be able to provide further information to the study group than they have been able to provide to the Feasibility Group. An additional important source of information will be studies on wild and domestic animals in the region of the sites.

Considering the importance of this aspect of the total problem, the material available from known sites should be examined and analyzed first. Then, the possibility of developing a background database of the overall exposures in the general population of the U.S. relative to suspected compounds should be explored. What is known regarding excess exposures in different situations will be established and specific areas in which appropriate exposure studies should be conducted will be defined. Conversely, there may be sufficient material already in the literature to permit evaluation of the general effects (or lack thereof) at higher levels of exposure, but this, again, almost certainly will require review by a group of experts.

3. Evaluation of Health Effects

In view of the many potential chemicals involved, no attempt will be made to generate primary data or evaluate raw data unless it is absolutely essential. Thus, data on health effects will be predominantly generated from previous reviews or assessments available within the general literature and other pertinent sources which are available to the public. Some of the various aspects that can be studied include:

i) Health Effects

Health effects will be inferred from what is known regarding potential levels of exposure and inferences drawn from high, intermediate, and low levels of exposure in other situations. Any attempt to relate low exposure level health effects to the multitude of chemicals which may occur, not only in relation to waste disposal, without considering the general background of the United States will be difficult and require careful evaluation but must be done. Thus, some attempt may be necessary to develop a profile on what is already known regarding exposures of the human population within the U.S., in terms of tissue deposits, etc., and their significance in disease patterns. Much of this material may, in fact, be available within the literature and could be the subject of further in-depth evaluation.

ii) Acute Effects

It will be important to define end points that can be examined with relative ease because they are not dependent on prolonged latent periods. Such effects should be closely related temporally to exposures if they are significant. Therefore, acute health effects may be susceptible to review whether as indicated by clinical, or clinico/pathological, or biochemical examination. Investigations of acute health-effect criteria should be standardized to a certain extent; criteria should be established to distinguish between organic and psychosomatic lesions. In this context, inferences drawn from occupational, accidental, and similar exposures at higher levels will provide pertinent data.

A list of end points will have to be examined to determine which are most likely to provide information of importance in evaluating health effects related to waste site exposures. Such end points would include:

a) blood studies;
b) urinary studies;
c) analysis of breast milk and other fluids and tissues;
d) evidence of respiratory, kidney, liver and other dysfunctions;
e) evidence of damage to infants, such as congenital malformations, cytogenic abnormalities, etc.

iii) Chronic Effects

Chronic effects, notably cancer, will require careful evaluation in light of the associated long latent period. In view of the small number of individuals liable to be exposed in relation to a particular waste disposal site and considering the known carcinogenic effects to be anticipated from suspected chemicals, it is quite possible that no conclusions can be reached regarding negative or positive findings in this context.

iv) Teratogenic and Mutagenic Effects

Following exposure to suspected chemicals, teratogenic and mutagenic effects may occur rapidly and are identifiable through congenital malformations, but many limitations apply to interpretation of the significance of several tests for mutagenesis. The assistance of CDC can be very valuable in this respect; toxicologists and epidemiologists with special expertise will be required to evaluate the findings.

v) Baseline Data

To compare the health status of individuals exposed to waste disposal sites deposits with that of the general population of the U.S., baseline data are required. Data from the ongoing Health Interview Survey and the second National Health and Nutrition Examination Survey (NHANES II) 1976-80 carried out by the National Center for Health Statistics would be used to identify a basic health profile of the U.S. population. With this information in hand, it may be possible to determine, on a broad basis, whether any indices can be attributed to proximity to waste disposal sites for an exposed population.

vi) Experience in Japan and Europe

Direct contact will be made with appropriate scientists and experts in Europe and Japan, who will participate as consultants to the task forces.

vii) Studies on Flora and Other Markers of Toxicity

A review of data from wild and domestic animals will be made and evaluated in terms of their implications for human disease.

In conclusion, the Feasibility Group agreed that a vast amount of material was available on a national and international scale from which significant and important inferences could be drawn as to the probable nature and extent of ill-health effects that could be anticipated as a result of previous waste disposal practices. In the past this material has been scattered and considered usually in terms of individual chemicals. However, a number of studies have been carried out on air pollution. In contrast, studies on chemically polluted water -- probably the most feared result of waste disposal -- are very poor and in terms of human disease are essentially negative, although the importance of water as a major source of human exposure has been shown for many of the suspected chemicals.

The possibilities of such a review are probably greater than originally believed and further analysis will be of great value in terms of the involvement and understanding of the academic research community.

4. Epidemiological Studies

In view of the small numbers of individuals likely to be involved in most waste disposal site exposures, epidemiological studies will be difficult to perform and will provide little information in most cases. Thus, the comprehensive review will of necessity have to contain an evaluation of the problems and limitations inherent in assessments of health effects related to individual sites. In addition, other methodologies for collecting material on a wider scale will have to be explored.

This particular aspect of the problem will be the subject of a specific task force. In this context, it will be desirable to further explore the experience of the Miami group in Florida as a base for calculating the overall extent of the problem.

5. Identification of Scientific Criteria for Classifying a Waste Disposal Site as an Imminent Health Hazard

This will arise out of the general discussion in the early portions of the survey and be addressed later by the Executive Panel which may, however, wish to redirect the question to one of the Task Forces.

C. ORGANIZATION OF THE STUDY APPROACH

The comprehensive review study will require an Executive Scientific Panel (ESP), two Task Forces (TF1 and TF2) and a full time scientific and support staff secretariat. The ESP will consist of 12 to 15 eminent academic scientists of international reputation. The ESP will be multidisciplinary in membership, including epidemiology, pathology, toxicology, biostatistics, oncology, occupational carcinogenicity, industrial hygiene, biochemistry, public health, toxic waste engineering, and other closely allied fields.

TF1 will address the universe of chemicals and aspects of exposure. TF2 will concentrate on human health effects. Both Task Forces will focus on additional issues and individual problems identified by the ESP and call upon appropriate experts from all sources to provide information and evaluation of the technical and scientific problems inherent in the investigation. A preliminary list of scientists identified as potential candidates for the ESP and Task Forces is attached (see Appendix IV).

In view of the nature of the subject and its unusual political and scientific ramifications, it is difficult to give an immediate outline of the procedures to be adopted by the ESP. These will depend, to a certain extent, on organization of a compatible panel of experts and their preliminary review of the problems and resources available. Accordingly, this necessitates a flexible approach to the initial scientific analysis and structure; the procedures outlined below should not be taken as definitive. It is a general principle that every effort will be made to take cognizance of and acquire any scientific information from any source pertinent to the overall problem, and these data will be freely available at the conclusion. Further, members of the committee will avoid obvious conflicts of interest. Lastly, adequate disciplinary representation and expertise should be included among the members to ensure wide exploration of all scientific viewpoints and to ensure credence in both the academic and public domain.

1. Management and Organizational Procedures (ESP)

While procedures must remain flexible, there are several aspects common to all evaluation studies. These include the following:

i) Preliminary conferences are held with key individuals to explore extant knowledge concerning hazardous waste disposal sites and to further identify experts with access to additional information.

ii) The purpose of these preliminary conferences is not only to identify additional individuals who may have pertinent knowledge or are engaged in research in related relevant topics, but also to define those scientific activities which may be most closely related to the particular type of evaluation. These discussions are used to generate a list of individuals as well as a list of key words to be used in computerized literature searching. Subsequent identification of key review articles and important information sources provide further expansion of the lists of potential consultants and pertinent key words.

iii) A definitive listing of pertinent parameters to be examined by the Executive Committee and Task Forces is prepared as appropriate based on an expanded review of current literature by the staff, current information on other aspects related to scientific evaluation, and consultation with key individuals concerning the scientists identified initially. In this case, care is taken to select all potentially pertinent information which will be balanced by the inclusion of work of investigators involved in related topic areas, or scientists holding divergent views concerning the subject.

iv) Typically, at this point a working paper will be prepared for the ESP by the professional scientific secretariat. This working paper describes the background of the issue and the extent of information available concerning the study topic. These papers, along with selected references, are sent to each participant prior to the ESP meeting at which the subject will be discussed.

v) Experience suggests that discussions with individual investigators or knowledgeable persons, as well as deliberations of the ESP at one to three-day meetings, coupled with a comprehensive literature review and analysis by the Task Forces, constitutes a reasonable basis for drafting an evaluation study. This draft report is prepared by the secretariat based on information obtained from the Task Forces, scientific literature, and from the discussions of the ESP. The draft report reflects documentation from the scientific literature and other valid information sources, as well as pertinent analysis and opinions of the Task Force members and/or ESP members. Where a controversial area exists, all aspects are discussed in considerable detail, and scientific references are given wherever possible. In instances where a consensus opinion of the ESP cannot be derived, an effort is made to include all divergent views.

vi) Drafts on individual topics are submitted to all members of the ESP as appropriate and, on occasion, to additional experts for their critical review and comment. Revision of the draft report is made by the staff based upon comments and emendations submitted by all participating consultants. The final draft may be resubmitted to the ESP for subsequent review and concurrence.

vii) The report of the ESP will be submitted to the UAREP Board for review and approval. This secondary review process ensures that the report will meet acceptable standards for scientific objectivity and fulfillment of study objectives.

viii) The Final Report will be published in toto and a synopsis will be published in the scientific literature.

2. Management and Organizational Procedures (TF)

The two Task Forces will be organized and will operate in an analogous manner, with certain exceptions. First, the ESP will play a major role in identifying qualified experts for membership on the two Task Forces. Second, membership on the Task Forces will be based primarily on scientific and disciplinary expertise with less emphasis on international reputation and possible conflict of interest.

Task Force reports, or series of reports, will be considered internal documents and will be exchanged between Task Forces, but delivered to the ESP. Task Forces are also considered *ad hoc* and may change in membership as determined by the ESP and secretariat. At least two ESP members will be on each Task Force.

3. Procedures to Assure the Adequate Identification as well as the Quality, Relevance, and Completeness of Data

Once specific problem areas have been identified relative to the universe of substances, exposure routes, health effects, etc., the ESP or a steering group of the ESP will explore i) information concerning a particular chemical, ii) toxic effects, and iii) identification of appropriate experts for consultation by the ESP for appointment to TF1 or TF2. Where appropriate, staff will visit investigators at their laboratories. The process of identifying and evaluating pertinent information will continue throughout the evaluation process, but it will probably not be possible to utilize sources of unanalyzed raw data.

Quality, relevance, and completeness of scientific data are a critical aspect of scientific evaluation. Experience dictates that the quality of data is related to the completeness of data and where these data may be found. In the final analysis, a reasoned judgment of the quality, relevance, and completeness of available data is a matter of a determination by the members of the ESP. The validity of the determination rests with the experience and reputation of the individuals who are selected to serve on TF1 and TF2, as well as with those on the ESP.

4. Elimination of Potential Bias and Conflicts of Interest Among Members of the ESP and TF1 and TF2

Evaluation studies of this type must use guidelines that include *ad hoc* self-terminating approaches, emphasis on the minimization of bias, and avoidance of quasi-permanent committees and appearance of vested interest. The following steps and techniques have proven successful in maximizing the objectivity of the input to evaluation studies:

i) Key individuals assist in the identification of potential ESP members and TF participants. These include members of the UAREP Board and other representatives of scientific societies who are able to identify knowledgeable scientists with expertise in particular study topics. The multiplicity of input provides ample opportunity to identify a wide diversity of potential participants. Every effort is directed towards balancing potential participants by the inclusion of consultants who may hold divergent views on a particular topic.

ii) In the course of developing an intensive literature database, it is possible to identify the specific contributions of potential participants to the study. Quality and objectivity of scholarly publications as well as reputation are evaluated by the project's staff.

iii) The final lists of ESP and TF members are reviewed by the UAREP Board. This review procedure is included to eliminate bias and potentially avoid vested interests following which an effort is made to informally contact each individual a second time to invite him or her to participate in the study.

iv) ESP and TF members are asked to complete a conflict of interest form. This form provides information on the extent of financial obligations and involvement in the public and private sectors which may bear upon the particular topic under evaluation. Procedures have been developed for maintaining the confidentiality of these statements; and an internal review is conducted by members of the UAREP Board. Specifically, the Executive Officer of UAREP, the President of UAREP, and the Business Manager of UAREP reviews each statement of conflict of interest for evidence of potential conflict. Where no conflict exists, forms are signed, sealed, and held until completion of the project. Where potential conflict is noted, the opinion of legal counsel is sought.

If and when conflict of interest is apparent, the scientist is informed, while a decision is made as to whether or not he or she should be given further consideration. If in the affirmative, the individual must agree prior to the evaluation study that, if at any point this conflict of interest is raised by the Executive Officer of UAREP or the project director, he or she would state for the meeting record non-participation in the deliberations or decision-making process of the Task Force or ESP.

5. Procedures to Resolve Conflicting Opinions

During Task Force meetings or during the deliberations of the ESP, the respective chairmen will ensure informal, harmonious discussions in which all participants are allowed to present data and comment on information presented. The chairmen must be selected for their experience in this context. Draft reports, revisions, and preparation of the final reports by the secretariat are written to reflect opinions of participating scientists and other knowledgeable individuals, documentation from the scientific literature, and pertinent analysis. Because the staff rapporteurs are recognized as professional scientists by all, the credibility of the document is further enhanced. Every effort is made to present and document divergent views, but to give a consensus of scientific opinion where appropriate. If a consensus is not appropriate, then divergent views are documented as completely and objectively as possible.

In cases where minority opinions are necessary, they are written by the secretariat based upon discussions with those dissenting members. Members with dissenting opinions are asked to indicate their identity and their concurrence with the material that has been independently prepared by the staff. This aspect is further strengthened by the subsequent secondary review and approval of the report by the UAREP Board.

6. Proposed Study Plan

The overall study comprises specific steps as follows:

Month 1: Identify Executive Scientific Panel and Chairperson

The ESP will be comprised primarily of members of the academic community with expertise in epidemiology, toxicology, biostatistics, experimental pathology, oncology, occupational carcinogenesis, industrial hygiene, biochemistry, public health, and toxic waste engineering. Emphasis will be placed upon obtaining the cooperation of individuals from the academic community who, insofar as possible, have no conflicts of interest or biases. These will be individuals recognized for their expertise in the particular relevant disciplines. There will be approximately 12-15 individuals on the Executive Panel. Budgetary considerations are based on a 15-member Executive Panel and five two-day meetings (or some combination of 10 days of meeting time).

One of the first individuals to be identified would be the Chairperson of the ESP. This individual should be available 100% of the time during the study period and should be recognized for his or her general expertise in review and evaluation of public health and scientific issues, rather than only for expertise in one particular discipline. Because most knowledgeable scientists in industry and government have ipso facto a conflict of interest, an effort will be made to recruit academic members of the scientific and medical community as ESP members.

Nominations will be accepted from all sources, including public announcements and specific requests to various communities concerned with toxic waste sites, such as industry, government, environmentalists, academic scientists, scientific societies, professional organizations, and other sources (e.g., the National Academy of Sciences, Carnegie Mellon Foundation, Ford Foundation, etc.). The primary criteria for membership on the Panel will be scientific expertise and freedom from conflict of interest or bias.

A list of potential invitees as members of the ESP will be prepared by the staff and forwarded to the UAREP Board for concurrence and selection. Individuals selected will be asked to serve on the Panel and to complete the conflict of interest information.

Months 2-3: Initial ESP Meeting

A two-day meeting for organizational purposes will be conducted. Prior to this Panel meeting, all members will have been invited and informed of the conditions of the appointment and the scope of the study. In addition, they will receive a working paper describing the project and an agenda for the meeting. At the meeting, the consultants will be asked to:

i) review and concur with the study plan or make modifications as they deem desirable,

ii) identify the need for Task Force activities and to provide a scope of work for those Task Forces, and

iii) identify individuals to serve on the several Task Forces.

It should be noted that at least two members of the ESP will serve on each Task Force as chairperson and vice chairperson (or recorder or rapporteur). Members of the Task Forces will be selected on the basis of scientific expertise and may include representatives of industry, government, academia, and other communities as required by the scope of Task Force activities.

Months 3-4: Appointment of the Task Forces

At the present time, we believe that only two Task Forces will be necessary.

Universe of Chemicals and Human Exposures Task Force (Task Force #1): The first activity of Task Force #1 (TF1) will be to evaluate the several lists of chemicals that describe the universe of substances found in hazardous waste disposal sites, and to finalize a finite list of substances likely to prove problematic in terms of hazardous waste disposal sites. It should be noted that at this stage, TF1 may require additional outside expertise from both government and industry as consultants.

The second activity of TF1 will be to examine information available on the substances in the finalized universe of chemicals, and to identify levels of probable exposure, methods or route of exposure, and duration of exposures that may prove to have some impact on human or animal health, and on the environment. TF1 will have seven to nine members and may utilize an additional five consultants. TF1 will meet four times for two days each.

Health Effects Task Force (Task Force #2): TF2 will consist of nine to eleven persons and will provide guidance in the evaluation of probable health effects that are to be anticipated in relation to hazardous waste disposal exposures of those chemicals within the universe of substances that have been determined to be potential exposure problems.

TF2 will consider acute and chronic health effects that are likely end points of exposure, information available from previous epidemiological studies and from occupational medicine, scientific evaluation of toxicity in laboratory animal studies, and data from other waste disposal sites. TF2 may wish to organize itself into subgroups. Additionally, it is expected that TF2 will require a greater input from staff in terms of literature and data analysis. TF2 may also require more time and meetings than TF1. TF2 will meet five times for two days each.

Months 3-6: Meetings of Task Forces

It is anticipated that TF1 must meet first and that TF2's progress will be dependent upon the output from TF1. The budget reflects a total of six meetings for the two Task Forces; however, it is anticipated that TF1 would meet twice and TF #2 would meet four times. Both TF1 and TF2 would draft reports, with the reports of TF1 being submitted to TF2.

The final output from TF1 would be a finalized list of problem chemicals, and information concerning environmental, animal, and human exposures that may prove to have demonstrable health effects. Emphasis would be upon human health effects. Clearly, this background information would be essential for TF2 in categorizing the likely end points or criteria for human health hazards and in identifying sources of data where the Health Effects Task Force would look for information relative to the toxic effects and potential health effects of the substances.

Months 4-7: ESP Meeting

Following the completion of the reviews of TF1 and TF2 and the completion of their draft reports, the ESP would utilize this information to create a draft of the review study report.

The conclusions of the review study draft report would point out what should be looked for in any waste disposal situation based upon extant scientific knowledge concerning the potential hazard to man, rather than upon political expedience, public complaints, or other reasons. A strong case would be developed for a reasoned judgment on scientific evidence of potential risk. The Tentative Final Report of the ESP would be published and made publicly available for comment.

Month 8: Open Public Forum

After publication of the Tentative Final Report of the ESP, an opportunity would be provided for all members of the public and the several communities of interested parties to come and address, either in writing or orally, the ESP at an Open Public Forum. The topic for discussion would be a review of and comments on the Draft Report in terms of garnering opinion as to the approach being presented and identification of any additional needs or deficiencies. This open public forum would be recorded and a transcript of the entire forum would be made available at cost to all participants. The ESP would be seated in front of the room and would listen to and accept all comments. The purpose of the Open Public Forum is information gathering and there would be no emphasis on entering into a dialogue or presenting the information in an adversarial manner. The organization and conduct of the open forum would be disseminated as widely as possible. In making arrangements for this, those individuals who wish to testify orally would be asked to provide written statements. Those not wishing to testify orally would be given deadlines for submission of written material. By negotiation, all oral testimony would be confined to a finite period of time.

Months 9-10: Review of Information Received

The ESP would meet a third time to discuss all information presented at the Open Public Forum and to revise as necessary the Tentative Final Draft of the Report. Based upon the decisions reached by the ESP in a review of the included comments, an attempt would be made to reach a consensus by the panel and a Final Report would be prepared. This Final Report would be provided to the sponsor of the study and would be disseminated widely and made available at cost to the public.

D. ESTIMATION OF COSTS

In analyzing the necessity of input from Task Forces and ESP, and to provide adequate time for review of the information collected by Task Forces, for preparation of Task Force reports, and for subsequent analysis of this information by the ESP and preparation of the Final ESP Report, as well as a desire to have informed public input, it seems logistically necessary to provide for a minimum of a 10-month period for the Comprehensive Review Study. The budget has been developed on the basis of 10 months. The budget also contains additional information concerning the number of meeting days for members of the Task Forces and panel.

COMPREHENSIVE REVIEW STUDY

10-Month Budget

Personnel[a]	Annual Salary Basis	10-Month Budget	
Project Director[b]	$ 62,400		
Staff Scientists[c] (2)	101,400		
Associate Scientists[d] (2)	58,800		
Administrative Assistant	24,953		
Technical Data Analyst	19,394		
Technical Literature Specialist	19,394		
Senior Secretary	17,958		
Clerk	12,226		
Subtotal	$316,525	$263,771	
Fringe Benefits & Payroll Taxes @ 28%		73,856	
Subtotal Personnel			$337,627
Consultants[e]			
a) Executive Scientific Panel 15 members @ $500/day 5 meetings - 2 days each		75,000	
b) Task Force #1 9 members @ $450/day 4 meetings - 2 days each		32,400	
c) Task Force #2 11 members @ $450/day 5 meetings - 2 days each		49,500	
Subtotal			$156,900

Travel and Per diem[f]		
Travel @ $600; per diem @ $100		
a) Executive Scientific Panel		
5x15x600	45,000	
5x2x15x100	15,000	
b) Task Force #1		
4x9x600	21,600	
4x2x9x100	7,200	
c) Task Force #2		
5x11x600	33,000	
5x11x2x100	11,000	
Subtotal		$132,800
Other Direct Costs[g]		
Telephone @ $600/month	5,400	
Postage and mailing (includes overnight mail) @ $975/month	8,775	
Expendible supplies	3,600	
Computerized literature retrieval @ $240/month	2,160	
Word processing @ $320/month	2,880	
Report preparation (2TF + 1 tentative + 1 final) 4 reports @ 150 pp. each @ $27/p., 550 cc.	16,200	
Duplication & photocopying, est. 216,000 @.07/p.	15,120	
Open public forum:[h]		
Hall rental for 2 days	1,100	
Transcript preparation	2,350	
Conference center expenses[i]		
1 meeting - 4 days	2,400	
Miscellaneous	975	
Subtotal		$ 60,960
TOTAL DIRECT COSTS		$688,287
INDIRECT COSTS[j] (39.6% of salaries, wages and consultant fees = $494,527)		$195,833
TOTAL COSTS		$884,120
FIXED FEE @ 10%		88,412
TOTAL CONTRACT		$972,532

BUDGET NOTES

a) All personnel are 100% FTE for 10-month period. It is essential that scientific staff be full time; some salary lapse with support staff may occur during months #1 and #10, but wage figures are not adjusted.

b) The Project Director would be a senior scientist (M.D. and/or Ph.D.) whose international reputation and scientific credentials are impeccable. His or her expertise would be in toxicology, pathology, and epidemiology.

c) Staff Scientists (2) would be mid-level M.D. or Ph.D. investigators with at least 10 years of professional experience and relevant education. Each would be initially assigned to a Task Force as staff coordinator. Staff scientists would be responsible to the Project Director and would play a major role in data collection and analysis, and preparation of reports.

d) Two M.S. or B.S. level associate scientists with at least 3-5 years experience in data analysis and review, as well as skills in scientific writing.

e) Consultant fees are based on the mid-point of daily fees paid by government contracts and private industry. Fees are necessary to attract and hold the most highly qualified persons as well as the necessity to require that they contribute substantially to the ESP and Task Force reports. Fees for ESP members are based on $500/day and those for Task Force members, $450/day. The budget assumes expert consultants from industry or government (as appropriate) would receive no compensation from UAREP.

f) $600 per trip is based on the average travel cost experience of UAREP and LSRO for 1982-83. Per diem is based on the daily rates for the Marriott Hotel, Bethesda, rate plus $24.00 per day.

g) Estimates derived from current projects and previous contractual activities of analogous scope and size.

h) Based on $550 per day (local Bethesda hotel rate).

i) One ESP meeting may be a four-day meeting outside the Bethesda area.

j) UAREP Indirect Cost rate at 39.6% estimated for 1983-84. Rate is based on total direct personnel salaries, wages, and consultant fees.

APPENDIX I

List of Persons and Organizations Consulted in the Feasibility Study

Patricia A. Buffler, Ph.D.
Associate Dean for Research and
Associate Professor of Epidemiology
University of Texas
Health Science Center at Houston
P.O. Box 20186
Houston, Texas 77025

Glyn G. Caldwell, M.D.
Deputy Director
Chronic Diseases Division
Center for Environmental Health
Centers for Disease Control
Atlanta, Georgia 30333

Philip Cole, M.D.
Professor and Head
Department of Epidemiology
and Biometry
University of Alabama
Tidwell Hall, Room 203
University Station
Birmingham, Alabama 35294

Morton Corn, Ph.D.
Johns Hopkins University
School of Hygiene and Public Health
615 North Wolfe Street
Baltimore, Maryland 21205

John E. Davies, M.D., M.P.H.
Chairman, Department of
Epidemiology and Public Health
University of Miami
School of Medicine
Medical Arts Building, Rm. 100
1550 N.W. 10th Avenue
Miami, Florida 33101

Perry J. Gehring, D.V.M., Ph.D.
Vice President of Agricultural
Products R&D
Director of Health and
Environmental Sciences
Dow Chemical U.S.A.
Bennett Building
2030 Dow Center
Midland, Michigan 48640

Joe W. Grisham, M.D., Ph.D.
Professor and Chairman
Department of Pathology
University of North Carolina
School of Medicine
Chapel Hill, North Carolina 27514

Clark Heath, M.D.
Director
Chronic Diseases Division
Center for Environmental Health
Centers for Disease Control
Atlanta, Georgia 30333

David G. Hoel, Ph.D.
Biometry and Risk Assessment Program
National Institute of Environmental
Health Sciences
P.O. Box 12233
Research Triangle Park, NC 27709

Irving Kessler, M.D.
Department of Epidemiology
and Preventive Medicine
University of Maryland
School of Medicine
655 West Baltimore Street
Baltimore, Maryland 21201

Herman F. Kraybill, Ph.D.
Scientific Coordinator for Environmental
Cancer
Division of Cancer Cause and Prevention
National Cancer Institute
Landow Building, Room C337
7910 Woodmont Avenue
Bethesda, Maryland 20205

Marshal S. Levine, M.D.
Department of Epidemiology
and Preventive Medicine
University of Maryland
School of Medicine
655 West Baltimore Street
Baltimore, Maryland 21201

William W. Lowrance, Ph.D.
Life Sciences and Public Policy
Program
Rockefeller University
1230 York Avenue
New York, New York 10021

Paul Lundy, M.S.
Toxic Substances Program
National Audubon Society
950 3rd Avenue
New York, New York 10022

John A. Moore, D.V.M.
Deputy Director
National Toxicology Program
National Institute of Environmental
Health Sciences
P.O. Box 12233
Research Triangle Park, NC 27709

Robert A. Neal, Ph.D.
President
Chemical Industry Institute
of Toxicology
P.O. Box 12137
Research Triangle Park, NC 27709

Glen Paulson, Ph.D.
Vice President for Science
National Audubon Society
950 3rd Avenue
New York, New York 10022

Russell Peterson, Ph.D.
President
National Audubon Society
950 3rd Avenue
New York, New York 10022

Carl Shy, M.D.
Department of Epidemiology
University of North Carolina
School of Public Health
Chapel Hill, North Carolina 27514

Ellen K. Silbergeld, Ph.D.
Environmental Defense Fund
1525 18th Street, N.W.
Washington, D.C. 20036

APPENDIX II

Literature and Reference Material
Reviewed by UAREP/LSRO in the
Feasibility Study
(March - May 1983)

100 - 199

Memoranda (originating outside FASEB)

File No.	From	Subject	Date
100	McKusick, B.	Potentially hazardous chemicals at disposal sites	12/1/82
101	McKusick, B.	Superfund priority sites	1/7/83
102	McKusick, B.	Corn Report (file #500)	1/4/83
103	Foege, W.	Transmits CDC report on long-term followups of populations exposed to toxic hazards, #506	6/21/82
104	Tozzi, J., OMB	Toxic Torts -- evaluating merits of alternative legislative proposals (sent by T. O'Leary, CMA)	4/18/83

GOVERNOR'S WASTE MANAGEMENT BOARD
CLAUD "BUCK" O'SHIELDS, JR.
CHAIRMAN

January 17, 1983

Honorable Joe Hackney
Legislative Building
Raleigh, NC 27611

Dear Representative Hackney:

The Governor's Waste Management Board is pleased to present to you a copy of our 1982 Annual Report. The Board makes several timely recommendations within the report which will require legislative action regarding the management of hazardous and low-level radioactive waste in North Carolina.

I urge you to take the necessary time to read and study this report and to give us your comments on the Board's activities and recommendations. If you desire additional information on the recommendations contained in the Annual Report, please notify our office of your needs.

I look forward to working with you on this most important program. Please call our office if we can be of assistance.

Sincerely,

Buck O'Shields

Buck O'Shields, Chairman
Governor's Waste Management Board

OFFICE OF THE GOVERNOR
RALEIGH 27611

JAMES B. HUNT, JR
GOVERNOR

GOVERNOR'S WASTE MANAGEMENT BOARD
CLAUD "BUCK" O'SHIELDS, JR
CHAIRMAN

Governor James B. Hunt, Jr.
State of North Carolina
State Capitol Building
Raleigh, North Carolina 27611

Dear Governor Hunt:

On behalf of the Waste Management Board, I am pleased to submit to you the first Annual Report describing the activities of the Board during 1982 and setting forth recommendations for administrative and regulatory action.

The members of the Board have worked diligently to fulfill the responsibilities of their appointments as set forth in the Waste Management Act of 1981, forever mindful of the intent of the Governor's Task Force on Waste Management in recommending the establishment of the Board. Foremost in the mind of every board member has been the charge made by the Governor's Task Force to "develop a system of waste management which is flexible enough to adjust to emergencies and changing technology, but is firm in its determination to prevent the generation of waste that cannot be disposed of safely" (Report of the Governor's Task Force on Waste Management, February, 1981). Protection of the health and environment of our citizens now and in the indeterminate future has been the Board's overriding concern.

Considering the enormity of our task, I feel that the Board has made great strides during 1982 toward the development of a comprehensive waste management program for North Carolina. Great progress has been made in assessing the volume, distribution, location, and physical and chemical characteristics of hazardous waste and low-level radioactive waste generated or disposed of in the state. The Board has evaluated the possible need to organize State agencies more efficiently to improve overall performance of waste management functions, and a Special Report on this issue is included in this report.

The Waste Management Board has also made great progress in legal issues pertaining to North Carolina's waste management program. Rules of Procedure were developed and filed for the Board to use when reviewing a petition to preempt a local ordinance that prohibits the establishment or operation of a hazardous waste facility or a low-level radioactive waste facility. Rules of Procedure were also developed and filed for the privilege license tax review process. By far the most difficult legal issue which the Board debated was the desirability of establishing by

325 North Salisbury St. Albemarle Bldg. Room 513 Raleigh, N. C. 27611 919/733-9020

statute a standard of strict liability for persons involved in storage, transportation or disposal of hazardous or low-level radioactive waste in North Carolina. The Board's recommendations on this issue are contained in Chapter II of this report.

Last, but certainly not least, the Waste Management Board succeeded in involving many more North Carolinians in the discussion and development of a better waste management program for North Carolina. A large number of guests attended and contributed their input at the Waste Management Board and committee meetings. The Board received and answered many requests for information from both industries and private citizens. The Board developed educational materials, conducted and co-sponsored several educational activities, and has begun planning for several more educational activities. Finally, the Board has instituted and widely publicized the annual program for the Governor's Award of Excellence in Waste Management.

The Waste Management Board is proud of the progress made thus far, and we hope that you will give careful consideration to the following recommendations explained in detail within this report. The Waste Management Board recommends that:

1. a Waste Management Coordinating Committee be established under the Governor's Waste Management Board to enhance and strengthen the present coordination that exists between State agencies and departments;
2. strict liability be applied by statute to any generator, transporter, treater or storer of hazardous waste in control of the waste at the time it causes injury to a claimant;
3. the Solid and Hazardous Waste Management Branch, Division of Health Services, Department of Human Resources, be given the authority by the General Assembly to require annual reports from all generators, treaters, storers and disposers of 1000 kilograms or more of hazardous waste in North Carolina;
4. sufficient funds be appropriated by the General Assembly for a reasonable regulatory program to protect the health, safety and environment of the people of North Carolina;
5. funding be appropriated by the General Assembly to monitor and clean up old waste sites.

The Board believes that implementation of the above recommendations can have a profound positive impact on North Carolina's ability to develop a safe effective waste management program which will better protect the health of the citizens and the environment.

The members of the Waste Management Board wish to thank you for this opportunity to serve you and the citizens of North Carolina. We look forward to continuing our work in 1983.

Sincerely,

Buck O'Shields

Claud "Buck" O'Shields, Chairman
Governor's Waste Management Board

CHAPTER I: ACTIVITIES DURING 1982 CATEGORIZED BY MANDATED FUNCTIONS AND POWERS

PART A: DESCRIPTION OF ACTIVITIES

ONE The Board shall periodically evaluate and assess the volume, distribution, location, and physical and chemical characteristics of hazardous waste and low-level radioactive waste generated or disposed of in the State.

An assessment of the volume, location, distribution, physical and chemical characteristics of hazardous and low-level radioactive waste generated or disposed of in the State is necessary in order to determine the extent of the problem North Carolina has in managing its industrial waste.

1. Hazardous Waste

On January 20, 1982 the Solid and Hazardous Waste Management Branch called for annual reports from the approximately 1,400 industries in North Carolina listed as major generators. The Federal Resource Conservation and Recovery Act had mandated that annual reports be filed with the states by major waste generators (those that produce more than 1,000 kilograms of hazardous waste per month) by March 1, 1982.

On March 15, 1982 the Department of Human Resources' Solid and Hazardous Waste Management Branch was notified that the Environmental Protection Agency had postponed its requirement that major generators of hazardous waste file annual reports.

By the time the State received notification of the postponing of the filing of the annual report, approximately 900 industries had already filed their annual report. Officials of the Solid and Hazardous Waste Management Branch anticipated, as did the Governor's Waste Management Board, that most of the remaining 500 industries would comply with requests for annual reports. As indicated in the annual report, 95% responded to the generator survey and 99% of the treaters, storers and disposers complied with the requests. This is important to note as once the Environmental Protection Agency postponed its requirement for the annual report, North Carolina, by law, could not require the annual report. G.S. 130-166.21D provides that no North Carolina regulation can be more restrictive than the federal regulations. It is felt by the Solid and Hazardous Waste Management Branch and the Governor's Waste Management Board that the State should continue to require an annual report for some period of time in order to track its program of managing hazardous and low-level radioactive waste.

The 1981 Annual Report as compiled by Mr. O. W. Strickland, Head of the Solid and Hazardous Waste Management Branch and his staff, now gives North Carolina its most complete inventory of hazardous waste generated within its borders. Copies of the report are available from the Solid and Hazardous Waste Management Branch and the Governor's Waste Management Board.

The Technical Committee of the Governor's Waste Management Board, in conjunction with the Technical Advisory Committee, is doing a more in-depth analysis of the materials furnished to the State in the annual reports filed by the generators, treaters, storers and disposers (for more detail, see page 16).
This analysis is scheduled for completion by February 18, 1983.

2. Superfund Sites

In February, 1982 the State was notified by the Environmental Protection Agency that 167 sites in 49 counties might contain hazardous waste that had been stored, treated or disposed of in the past (documentation available upon request). The locations of the sites range from the mountains to the coast, and include industrial plants, military facilities, municipal and county landfills and abandoned garbage dumps. Many of the sites have been around for a long time, some since 1933.

These sites were identified in a list compiled under the Comprehensive Environmental Response, Compensation and Liability Act of 1980, commonly known as the "Superfund" Act. All sites were inspected in a cooperative effort with the Solid and Hazardous Waste Management Branch in the Department of Human Resources, the Division of Environmental Management in the Department of Natural Resources and Community Development, and the Environmental Protection Agency. After preliminary inspections of all sites, it was determined that only 9 sites pose a threat to human health thereby requiring monitoring and possibly some remedial action. Two sites have since been cleaned up, one with superfund money and one by the owner. The State continues to monitor the remaining 7 sites.

The Waste Management Board's recommendation concerning funding for monitoring and cleaning up old waste sites is in Chapter II, page 60.

3. Low-Level Radioactive Waste

At the request of the Waste Management Board, the Radiation Protection Section of the Division of Facility Services, Department of Human Resources collected data to determine the quantities and types of low-level radioactive waste disposed of by North Carolina industries, research institutions and medical facilities for the period June 1, 1981 - July 30, 1982.

According to the survey, 23 facilities reported some type of low-level radioactive waste disposal. Almost 57% of the volume of low-level radioactive waste generated in North Carolina during the reporting period was disposed of by transfer to the Chem Nuclear Disposal Site in Barnwell, South Carolina. The remaining 43% is disposed of by transfer to the disposal site in Richland, Washington. In terms of the quantity of radioactive material in Curies, over 97.5% is disposed of by transfer to the South Carolina disposal site; only 2.5% goes to the site located in Washington State.

The report cites possible problems for low-level radioactive waste disposal in North Carolina due to severe volume limitations and restrictions which preclude acceptance of certain types of waste at the South Carolina Disposal Site, as well as mounting efforts to prevent access to the Washington State Site.

The report was presented to the Board in December, 1982. This data will greatly assist the State in determining facility needs for safely managing low-level radioactive waste generated within its borders.

TWO The Board shall periodically review the State's comprehensive waste management system and make recommendations to the Governor, cognizant State agencies, and the General Assembly on ways to improve waste management; reduce the amount of waste generated; maximize resource recovery, reuse, and conservation; and minimize the amount of hazardous waste and low-level radioactive waste which must be disposed of.

---

1. Waste Management Technology

The Waste Management Board, especially members of the technical committees (Technical Committee, Technical Advisory Committee on Hazardous Waste and the Technical Advisory Committee on Low-Level Radioactive Waste), has received information, held discussions, and in some cases made recommendations regarding the following areas of waste management technology:

a. Ms. Betsy Dorn, Director of the Piedmont Waste Exchange at the University of North Carolina at Charlotte, presented a report on the role the Waste Exchange can play in educating and promoting the recycling and exchanging of waste materials in North Carolina. As a service of the Waste Information Research and Exchange Program of UNCC, information, research, and education services are utilized to assist Carolina industries with developing waste management strategies that are safe and economical.

b. In February, Mr. Dave Roche, Duke Power Company, gave a slide presentation on fossil fuel combustion and PCB burn. Mr. Roche explained how complete combustion of the fuel depended on the temperature, residence time, and the amount of oxygen present. He also explained the 100 MW pulverized coalfired boiler used at Duke Power's Riverbend Steam Station where waste PCB-contaminated transformer mineral oil was incinerated. A copy of Mr. Roche's presentation is attached in Appendix 2:1.

c. Also in February, Dr. Pete Andrews of the Institute of Environmental Studies explained what the Institute had been doing specifically in the areas of hazardous waste.

d. The Technical Committee heard a presentation by Jim Gilpin with Associated Technologies, Inc. summarizing the current processes available for Waste Volume Reduction (available upon request).

2. State Government Organization, Policy, Legislation and Funding

The Waste Management Board has received information, held discussions and made recommendations concerning the need for changes in State Government in regard to organization, policy, legislation or funding.

a. The Waste Management Board has discussed whether or not to recommend to the General Assembly the removal of G.S. 130-166.21D from the environmental legislation passed in North Carolina since 1973. The Board asked the state departments to look at EPA changes and what actions may be necessary for the General Assembly to take in 1983.

b. The Waste Management Board discussed an issue paper concerning sufficient funds to allow for a reasonable regulatory program to protect the health, safety, and the environment of North Carolinians and North Carolina's natural resources.

c. The Waste Management Board has discussed the state's need for funding to be able to monitor and clean up old waste sites that are determined to be a threat to North Carolina and its people.

d. The Waste Management Board has discussed the question of what to do in emergency or spill situations, i.e., where do we dispose of these, usually toxic, wastes?

e. The Waste Management Board has been asked to consider the current loop-hole in state law (G.S. 10F.0029) that allows municipal wastewater treatment facilities to become hazardous waste facilities, as industry processing wastes are discharged into sewer systems.

f. The Waste Management Board discussed the need for the General Assembly to authorize state agencies to require annual reports from generators, treaters, storers, and disposers.

g. The Waste Management Board has discussed the question of what wastes or waste residuals that North Carolina should not allow to be placed in burial facilities.

THREE The Board shall study and make recommendations on policy issues including but not limited to liability and financial responsibilities within the waste management area. On or before January 1, 1983, the Board shall prepare and present to the Governor and General Assembly a report concerning the desirability of establishing by statute a standard of strict liability for persons involved in storage, transporation, treatment, or disposal of hazardous or low-level radioactive waste in North Carolina.

The Waste Management Board assigned this function to its Legal Committee for study and recommendations. Several key policy questions were discussed in determining whether to support strict liability, and, if so, in what form. These policy questions included:

* For what risks or injuries will strict liability be imposed?
* How will the establishment of a standard of strict liability affect the cost of insurance for waste management facilities?
* Who or what types of activities should be subject to strict liability? Generators? Disposers? Transporters? Successors in interest? Others?
* Is strict liability to be handled through the courts or is a separate system to be established for this purpose?

The Legal Committee presented a report of its findings concerning the desirability of establishing by statute a standard of strict liability and other liability issues to the Waste Management Board on December 1, 1982. The Board voted to approve the twelve recommendations of the Legal Committee for presentation to the Governor and the General Assembly. These recommendations are presented in the "Special Report and Recommendations on Liability Issues," beginning on page 44.

FOUR The Board shall promote research and development and disseminate information on state-of-the-art means of handling and disposing of hazardous waste and low-level radioactive waste. The Board is authorized to establish a waste information exchange for the State.

---

1. Hazardous Substances in North Carolina Public Schools

The Waste Management Board's Public Information Committee has met several times with the Department of Public Instruction to discuss plans for addressing the problems of storage, use and disposal of hazardous and toxic substances found in North Carolina schools.

The public schools of North Carolina have expressed a strong need for help with initiating a management system for the hazardous substances used in four major curriculum areas: a) Science Departments; b) Art Departments; c) Industrial Arts; and d) Vocational Education.

With the technical assistance of the Waste Management Board, the Department of Public Instruction proposes to identify chemical substances which should be removed from the schools, provide for the pickup and disposal of these chemicals, and provide guidelines and teacher training in the safe use of chemicals left in the schools (documentation available upon request).

2. Pollution Prevention Pays Symposium

On May 26-27, 1982, the Governor's Waste Management Board co-sponsored an educational symposium entitled "Pollution Prevention Pays" to promote the innovative new ways industries are finding to minimize or prevent the production of pollutants, while at the same time reducing production costs. Approximately 225 representatives from industry, waste management firms, government and other organizations were in attendance.

In addition, the Waste Management Board aided in the distribution of the "Pollution Prevention Pays" supplement printed in the Charlotte News and Observer. Proceedings of the symposium are now available in book form.

3. Research Projects

The Waste Management Board cooperated with the Governor's Board of Science and Technology to select the following research projects on hazardous or low-level radioactive waste.

Siting Waste Management Facilities, R. Andrews and F. Runge, University of North Carolina - Chapel Hill.

Effectiveness of "Clay Liners", J. Pierce, Duke University.

Improving Pollution Monitoring Methods, M. Kimberly, North Carolina State University.

Evaluating Potential Disposal Sites, C. W. Welby and I. J. Won, North Carolina State University.

Mercury in Wastewater Treatment Systems, J. S. Wu and H. Hilger, University of North Carolina - Charlotte.

Evaluating the Effect of Hazardous Waste Disposal Sites Upon Groundwater Aquifers, R. Janardhanam, University of North Carolina - Charlotte.

Local Emergency Response to Hazardous Materials Accidents, E. A. Holland, M. H. Ford, and E. W. Blaha, Triangle J Council of Governments.

The findings of these studies will be presented to the Waste Management Board upon their completion during 1983.

4. Workshops

The Chairman and one member of the Waste Management Board have attended a two-day workshop given by the Industrial Extension Service of North Carolina State University with support from the Solid and Hazardous Waste Branch of the Department of Human Resources entitled "Hazardous Waste Management Under RCRA". This workshop, given nine times to over 270 individuals, was found to be excellent by the attending Waste Management Board members. These and other workshops and supporting manuals developed by Industrial Extension Service have been applauded by the Governor's Waste Management Board and staff, and the Governor's Waste Management Board has encouraged participation in these educational programs. Further information regarding these programs is available in the office of the Waste Management Board.

5. Waste Information Exchange

Although the Waste Management Board is authorized to establish a waste information exchange for the state, the Board has not taken such an action during 1982. Rather, the Board has expressed the view that waste information exchange can be conducted more effectively and more appropriately by the three waste exchange programs which already operate in North Carolina. These are:

Piedmont Waste Exchange
Urban Institute
Department of Urban & Environmental Engineering
UNC at Charlotte
UNCC Station, NC 28223
(704) 597-2307
Contact: Betsy Dorn

Atlantic Coast Exchange
PES, Inc.
1905 Chapel Hill Road
Durham, NC 27707
(919) 493-3536
Contact: Doug Kent

National Waste Exchange
Route 12, Box 255A
Winston-Salem, NC 27107
(919) 769-2668
Contact: Carl Wilkins

FIVE The Board shall promote public education and public involvement in the decision-making process for the siting and permitting of proposed waste management facilities.

---

1. Public Input

Public attendance and input was encouraged at meetings of the full Waste Management Board and at all committee meetings. At all meetings, guests from the general public were given ample opportunity to voice their concerns and ask questions.

To maximize citizen participation in the activities of the Waste Management Board, the following measures have been taken:

a. Members were added to the Public Information/Participation Committee from the general public;

b. Meetings were held outside of Raleigh in Tarboro and Winston-Salem; and

c. Some meetings were held in the evening.

Lists of citizens who attended the Board and committee meetings are on file in the office of the Waste Management Board.

2. Public Participation

The Waste Management Board discussed the concerns of several citizen groups in regard to public participation in the siting of hazardous waste facilities. In response to these concerns, the Waste Management Board took the following actions:

a. The Waste Management Board mailed a letter to the North Carolina Association of County Commissioners and the North Carolina League of Municipalities recommending that their constituent members establish Citizen Involvement Committees on hazardous waste in order to develop a body of local knowledge, to educate the general public on hazardous waste issues, and to prepare to participate in local hazardous waste siting issues, if required (Appendix B-1). Counties which have established citizens' committees on waste management include:

Anson
Bladen
Buncombe
Cumberland
Guilford
Lee
New Hanover

b. The Waste Management Board drafted, and adopted as working policy, Proposed Procedures for Public Participation in North Carolina's Hazardous Waste Permitting Process (available upon request from the office of the Waste Management Board). These procedures outline the type of interaction between local citizens, the permitting authority, the applicant and the Waste Management Board which the Board considers desirable. The procedures emphasize that:

(1) An informational package should be established to prepare and educate localities concerning disposal/treatment of hazardous wastes.

(2) Negotiation between local citizens and the facility developer is strongly encouraged.

(3) Local concerns and agreements with the facility developer must be given merit by the reviewing agencies.

(4) Local agreements must be incorporated into the review before a tentative decision is made by the permitting authority.

It should be noted that there is no mechanism within existing permit procedures to require adherence to these proposed procedures, and additional consideration needs to be given to methods for implementing these procedures.

c. The Public Information/Participation Committee has begun development of a public information package including:

(1) A Waste Management Board brochure (complete);

(2) A Citizen's Handbook and Decision-Making Guide on the hazardous waste facility siting process (in progress);

(3) A Citizen's Guide to negotiation in siting hazardous waste management facilities (in progress); and

(4) A North Carolina Waste Management Directory listing sources of information and technical assistance concerning hazardous and low-level radioactive wastes (in progress).

The projected completion date for these materials is February 28, 1983.

3. Public Hearings

A public hearing was held on August 26, 1982, on the proposed rules involving the procedures for the preemption process and the privilege license tax review. Comments from the public were heard at this time and written comments were accepted for two weeks following the hearing. These comments were discussed and incorporated into the procedures before final approval.

SIX The Board shall periodically evaluate and assess the type and number of hazardous waste facilities, hazardous waste landfill facilities, low-level radioactive waste facilities and low-level radioactive waste landfill facilities in existence, under construction or planned in the State and multi-State region and promote the development of additional facilities particularly retrievable above-ground storage facilities if existing or planned facilities are deemed inadequate or unavailable.

An accurate evaluation of the type and number of waste management facilities could not be done until up-to-date information was reported by the generators, treaters, storers and disposers of hazardous waste in North Carolina. As soon as these data were received from the Solid and Hazardous Waste Management Branch of the Division of Health Services, the Waste Management Board developed a Request for Proposal for an "Analysis of North Carolina's Industrial Waste." The scope of the project is outlined below.

a. Review data obtained by the Office of Solid and Hazardous Waste in its 1981 report on generators, treaters, storers and disposers of hazardous waste in North Carolina and any other pertinent data available from the state.

b. Identify hazardous waste generated in North Carolina that can be recycled or otherwise recovered through known techniques either by the generator, other industries through waste exchange or by special resource recovery facilities; estimated volumes; and recommendations as to the number and types of facilities or processes that may be needed in North Carolina to manage hazardous waste.

c. Identify the commercially operated hazardous waste treatment facilities operating in North Carolina and the types of waste that can be handled by these facilities.

d. Identify the best available technology known for the destruction or rendering to a less hazardous state the waste generated in North Carolina and subsequent disposal procedure of the residues.

e. Identify and support with conclusions of known facts those wastes treated or non-treated that should be prohibited from land disposal due to the risks they present to human health and the environment.

f. Identify and support with conclusions of known facts the most appropriate method for disposal of those wastes identified in item "e" above.

g. Identify methods of stabilizing wastes or waste residue for those wastes which have been specifically identified as safe for land disposal.

The Board has awarded a contract to Tracor Jitco, Inc. (Research Triangle Park), which will complete the analysis by February 18, 1983.

When the Board receives this report, the recommendations concerning the number and types of facilities needed will be modified as necessary. A Supplemental Report of the Board's findings and recommendations will then be submitted to the Governor and the General Assembly.

SEVEN The Board shall prepare and file jointly with the Governor and the General Assembly an annual report describing the Board's activities and setting forth its recommendations for administrative or regulatory action required to improve the State's comprehensive waste management system or remedy noted defects in the system. A special report shall be filed in January of 1983 which shall include an evaluation on the possible need to organize State agencies more efficiently to improve overall performance of waste management functions. The report should give consideration to the advantages and disadvantages of consolidating or centralizing administration of programs that are now in separate agencies.

---

1. Annual Report

This document constitutes the first Annual Report of the Governor's Waste Management Board. The report was drafted by staff members, approved by the Board on January 5, 1983, and presented to the Governor and the General Assembly in mid-January.

The Annual Report of the Governor's Waste Management Board describes the activities of the Board since its creation on June 26, 1981, when the North Carolina Waste Management Act was ratified. The Annual Report also sets forth recommendations for administrative or regulatory action required to improve the State's comprehensive waste management system or remedy noted defects in the system. These recommendations are summarized within the letter of transmittal to Governor Hunt and discussed in detail in Chapter II.

2. Special Report on State Agency Reorganization

The Waste Management Board gave careful consideration to the many advantages and disadvantages of consolidating or centralizing administration of programs that are now in separate agencies. The Waste Management Board decided not to recommend any major reorganization of State agencies at this time. Rather, an issue paper recommending the establishment of a Coordinating Committee was developed by staff and circulated to the Secretaries of the relevant state agencies for comment This issue paper was discussed at length and revised to reflect the needs of all parties involved.

The Special Report mandated in the North Carolina Waste Management Act was approved by the Waste Management Board at its meeting on October 27, 1982, and submitted to the Governor and the General Assembly in January, 1983 as Chapter II.A. of this report. The Waste Management Board sincerely believes that the actions recommended within the Special Report, if implemented, would greatly increase efficiency within State agencies and improve the overall performance of waste management functions in state government.

EIGHT The Board shall each year recommend to the Governor a recipient for a "Governor's Award of Excellence" which the Governor shall award for outstanding achievement by an industry or company in the area of hazardous waste or low-level radioactive waste management.

The process and criteria for the selection of nominees and award recipients was developed by the Public Information/Participation Committee with assistance from the Technical Committee, individuals in private industry, and interested citizens.

Nomination forms for the 1982 awards were developed and mailed out to the following groups:

Chair, Boards of County Commissioners
State Agencies
Consulting Firms
Trade Associations
North Carolina Economic Development Contact List
Local Citizens Groups
Chambers of Commerce
Generators of Hazardous Waste
Generators of Low-Level Radioactive Waste

The Piedmont Waste Exchange graciously volunteered to help in the distribution of over 600 forms as an insert in its newsletter, "The Waste Watcher."

Nominations were also solicited through press releases to business editors of local newspapers and trade magazines and a radio show describing the awards program which aired on 75 stations in North Carolina.

Nominations will first be screened by the Technical Committee, and then reviewed by a panel of judges comprised of:

1 member from the Waste Management Board
1 member in the "public eye," i.e., an elected official

1 member from the university system
2 representatives of industry

The panel of judges for 1982 was:

Dr. Russell Christman, Chairman
Department of Environmental Science & Engineering
School of Public Health
Chapel Hill, NC

Robert Thompson, Physical Scientist
Environmental Sciences, Northrop Services
Research Triangle Park, NC

Jane Sharp, President
Conservation Council of NC
Chapel Hill, NC

Bill Holman, Member
Governor's Waste Management Board
Raleigh, NC

Winslow Hartford, Retired Chemist
Allied Chemical
Professor, Belmont Abbey
Charlotte, NC

Nominees will be judged on the basis of the following criteria:

* Environmental benefits
* Economic returns
* Technological achievement
* Superior management and engineering
* Commitment by company
* Leadership
* Creativity

The final recommendation for the award recipient will be made to the Governor in January, and an awards ceremony will be held in February of each year.

NINE The Board shall promote and participate in discussion with other states concerning development of regional hazardous waste and low-level radioactive waste management agreements.

In December 1980, Congress enacted the Low-Level Radioactive Waste Policy Act of 1980. This legislation declares as a matter of national policy that each state is responsible for providing for the availability of capacity for the disposal of low-level radioactive waste generated within its own borders. Congress also declared that such waste could be most safely and efficiently managed on a regional basis, and it authorized the states to enter into compacts with other states to provide for the establishment and operation of regional disposal facilities for low-level radioactive waste. Constitutionally, a compact is defined as an interstate agreement that requires Congressional approval. This legislation also allows interstate agreements to restrict importation of waste from other regions.

Soon thereafter, representatives of the Governor of North Carolina met with representatives of the governors of other southeastern states to frame an interstate compact for the management of low-level radioactive waste. These negotiators were assisted by the legal staff of the Southern States Energy Board. Meetings were held at 60 day intervals during 1981. In 1982, eight state legislatures considered drafts of compacts and two clusters of states were identified for membership eligibility in the compacts. North Carolina was named as a prospective member of each group and its representatives participated in the exploratory talks conducted in each of these regions.

Essentially, the North Carolina negotiating position included the following elements. The interstate agreements should contain a regional plan for the comprehensive management of all types of low-level radioactive waste, and a regional commission should have the authority to administer the management plan. The entire program should be funded from user fees, collected by the operators of regional facilities, except that an eligible state might be required to pay an entry fee as a condition for membership. The compact commission should have the power to regulate the importation and exportation of wastes as a means of managing known volumes and classes of waste material. Each member state should expect to contribute something to the regional program. There should be no exemptions or special inducements granted for membership, and no special requirements imposed on any state as a condition of membership.

In the summer of 1982, seven governors and their representatives met in Hilton Head Island, South Carolina. They reviewed the work of their representatives and the results of the negotiations since 1980. They agreed to work for the adoption of an interstate compact with the existing facility at Barnwell, South Carolina serving as the first regional disposal facility. Subsequently in meetings at Birmingham and Atlanta, it was agreed that, in addition to the host state of South Carolina, the eligible states would include Alabama, Florida, Georgia, Mississippi, North Carolina, Tennessee and Virginia. Most of North Carolina's other negotiating points were also accepted.

In 1983, the legislatures of each of the eight eligible states will meet in regular session, and the proposed compact will be submitted to them for approval. Although the content of the draft compact has been accepted by the gubernational negotiators, the actual text of the agreement has not been finalized in the appropriate legal form. It is expected that, with the help of the staff of the Southern States Energy Board, the negotiators will agree on the proper form of the document and the sequence for its submission to the various legislatures.

At this time, only one regional compact (Northwest) has been submitted to the Congress for approval. It is possible that the southeastern states' agreement could be submitted as early as mid-1983.

North Carolina's representatives to the 1982 negotiations were Jack Cozort, the Governor's Legal Advisor; Captain William Briner, member of Governor's Waste Management Board; and Robert Jansen, Governor's Senior Policy Advisor. Captain Briner and Mr. Jansen reported to the Waste Management Board throughout the year concerning the progress of the negotiations.

TEN The Board shall assist localities in which facilities are proposed in collecting and receiving information relating to the suitability of the proposed site. At the request of a local government in which facilities are proposed, the Board shall direct the appropriate agencies of State government to develop such relevant data as that locality shall reasonably request.

---

1. Inquiries from Citizens

On several occasions, local citizens from counties in which facilities were proposed have attended meetings of the Waste Management Board and its committees. These citizens have been given the opportunity to ask questions and present their views. Citizens' questions have been answered during the meetings whenever possible; other requested information has been furnished as quickly as possible after the meeting.

2. Meeting with Citizens' Group

A member of the Waste Management Board, Mrs. Virginia Newell, and two members of the Department of Human Resources staff met with approximately 100 Greensboro citizens on the evening of January 28, 1982. The meeting was held at the request of citizens concerned about a waste treatment facility which was being proposed for the Pomona section of Greensboro. Mrs. Newell, Bryant Haskins, and Bill Meyer shared information about the permitting process and heard the concerns of the citizens.

3. Local Briefings

In addition, the Waste Management Board plans to conduct "local briefings" in localities in which facilities are proposed. The "local briefings" will be for the exchange of information only, and not to be conducted as a meeting to weigh the merits or impacts of the proposed facility. The Waste Management Board would present information on the

State's permitting process for hazardous waste management facilities, and might assist the locality in developing a negotiation process and plan of action. The Board would also present information concerning the licensing program for all radioactive material users in North Carolina.

4. Information Package

The Public Information/Participation Committee has begun developing a printed informational package for local citizens. This package is to include a Citizen's Handbook, structured to guide and help all participants in the hazardous waste facility siting process address and make decisions as the process unfolds. It will indicate available sources of assistance and information, raise pertinent questions to be answered, and pinpoint specific requirements of participants at each phase of the process. The Waste Management Board plans to print and make available approximately 250 copies of the Citizen's Handbook.

A North Carolina Waste Management Directory and a bibliography are also being developed by the Public Information/Participation Committee and staff. These materials will not be used for mass mailing, but rather they will be mailed in response to individual requests for information.

ELEVEN The Board shall, in accordance with the procedures set forth in G.S. 130-166.17B and G.S. 104E-6.2, make requisite findings and submit its recommendation to the Governor concerning the exercise of the State's preemptive powers.

Under the Waste Management Act of 1981, the Governor's Waste Management Board may recommend to the Governor that the State act to preempt local ordinances that prohibit or prevent establishment or operation of a hazardous waste facility or a low-level radioactive waste facility. G.S. 130-166.17B(c) states that the Board can recommend preemption only if it finds:

1. The facility is necessary to establish adequate capability for management of waste in North Carolina and serves the interest of the citizens of the state as a whole.
2. All legally required state and federal permits have been issued.
3. Local citizens have had adequate opportunity to participate in the decision making process.
4. The construction and operation of the facility will not pose an unreasonable health or environmental risk to the surrounding locality and that the facility developer or operator has taken or consented to take any reasonable measures to avoid or manage forseeable risks and to comply to maximum feasible extent with any applicable ordinance(s).

The Governor can make a final decision only after making the above four findings.

The Legal Committee of the Waste Management Board identified several experts who could be helpful with this function. Three experts agreed to assist the Legal Committee: Bill Campbell, Institute of Government; Don Liner, Institute of Government; and Richard "Pete" Andrews, UNC Institute for Environmental Studies.

Mr. Liner and Mr. Andrews prepared a position paper on the question of how to decide what the Board will consider in determining whether or not there is a "need" for a facility in North Carolina if the Board is petitioned to review an ordinance which prohibits the facility. This issue paper is available from the Waste Management Board's office upon request.

The Committee decided not to try to define "need", but rather for the Board to make this determination on a case-by-case basis considering the circumstances of each case at the time it is presented.

Thus, the Legal Committee agreed to proceed with establishing rules of procedure without defining the "need". On May 26, 1982, the Board voted unanimously to accept the proposed rules and send them to public hearings.

A public hearing was advertised according to the North Carolina Administrative Procedures Act and held at the August 27 Board meeting. The hearing was held open for written comments for 14 days. Comments were received from the following individuals and organizations:

1. William C. Capel, Jr., Attorney for County of Anson;
2. James E. Wall, Jr., Chairman, Anson County Hazardous Waste Management Board;
3. Catherine M. Cameron, Chairperson, Chatham County Chapter, Tri-County Alliance;
4. Jerry T. Roberts, Secretary-Treasurer, North Carolina Textile Manufacturers Association, Inc.;

5. Daniel Read, Acting Executive Coordinator, Conservation Council of North Carolina;

6. Angela Skelton, Associate Director, North Carolina Petroleum Council.

These comments were summarized and presented to the Board, and several of the comments received were incorporated into the rules of procedure. The final form of the rules of procedure for the limited preemption process were adopted by the Board on October 27, 1982 and can be found in Appendix B-7.

TWELVE The Board shall, in accordance with the procedures set forth in G.S. 160-A-211.1 and G.S. 153A-152.1, review upon appeal specific privilege license tax rates which localities may apply to waste management facilities in their jurisdiction.

The Waste Management Act of 1981 authorizes municipalities and counties to levy a privilege license tax on hazardous waste and low-level radioactive waste facilities located in their jurisdiction. (G.S. 160A-211.1 and G.S. 153A-152.1). The locality is authorized to levy a privilege license tax in an amount designed to compensate for the additional costs incurred by having a facility in its jurisdiction.

The Governor's Waste Management Board is authorized to hear appeals from any person or firm taxed under this authority, thus acting as an administrative review body for the purpose of determining the reasonableness of any such tax. The statute does not set out the specifics of this appeal process, leaving it for the Board to establish by regulation.

Two outside experts, Bill Campbell of the Institute of Government and Richard "Pete" Andrews of the UNC Institute for Environmental Studies, agreed to assist the Legal Committee with this function. The Legal Committee decided that it would be unwise to try to define what factors the Board would use in determining whether or not a privilege license tax is reasonable because to do so might limit improperly the factors that localities consider. Rather, the Committee decided that the Board should make this finding on a case-by-case basis.

A public hearing was advertised according to the North Carolina Administrative Procedures Act and held at the August 27 Board meeting. The hearing was held open for written comments for 14 days. Comments were received from the following individuals and organizations:

1. William C. Capel, Jr., Attorney for County of Anson;
2. James E. Wall, Jr., Chairman, Anson County Hazardous Waste Management Board;
3. Catherine M. Cameron, Chairperson, Chatham County Chapter, Tri-County Alliance;
4. Jerry T. Roberts, Secretary-Treasurer, North Carolina Textile Manufacturers Association, Inc.;
5. Daniel Read, Acting Executive Coordinator, Conservation Council of North Carolina.

The comments were summarized and presented to the Board and several of the comments were incorporated into the rules of procedure.

The Rules of Procedure for the Privilege License Tax Review process were adopted in final form by the Board on October 27, 1982, and can be found in Appendix B-11.

THIRTEEN The Board may insure its members against personal liability for any actions they might take pursuant to the exercise of the functions and powers of the Board.

A memorandum was presented to the Board from the Attorney General setting out the potential for liability on the part of Board members and the statutory responsibilities and policies of the Attorney General in representing them if they should be sued. A copy of the memorandum may be obtained from the Governor's Waste Management Board's office.

FOURTEEN The Board may adopt, modify, or revoke any rules necessary to carry out the functions and powers as set forth in this part.

The Board adopted rules of procedure to be used by the Governor's Waste Management Board in:

1. Reviewing petitions for limited preemption of a local ordinance pursuant to the authority set forth in NCGS 130-166.17B and 104E-62.;
2. Reviewing upon appeal specific privilege license tax rates which localities may apply to waste management facilities in their jurisdiction.

These rules of procedure may be found in Appendix B-7 and B-11. The development of these rules is described on pages 27-31.

FIFTEEN The Board shall have any and all powers necessary or incidental to the exercise of the functions and powers enumerated herein.

This is a mandated power, and not a function, of the Waste Management Board. Therefore, there are no activities to report for this item. To date, the Waste Management Board has indeed had the powers necessary to fulfill its mandated functions.

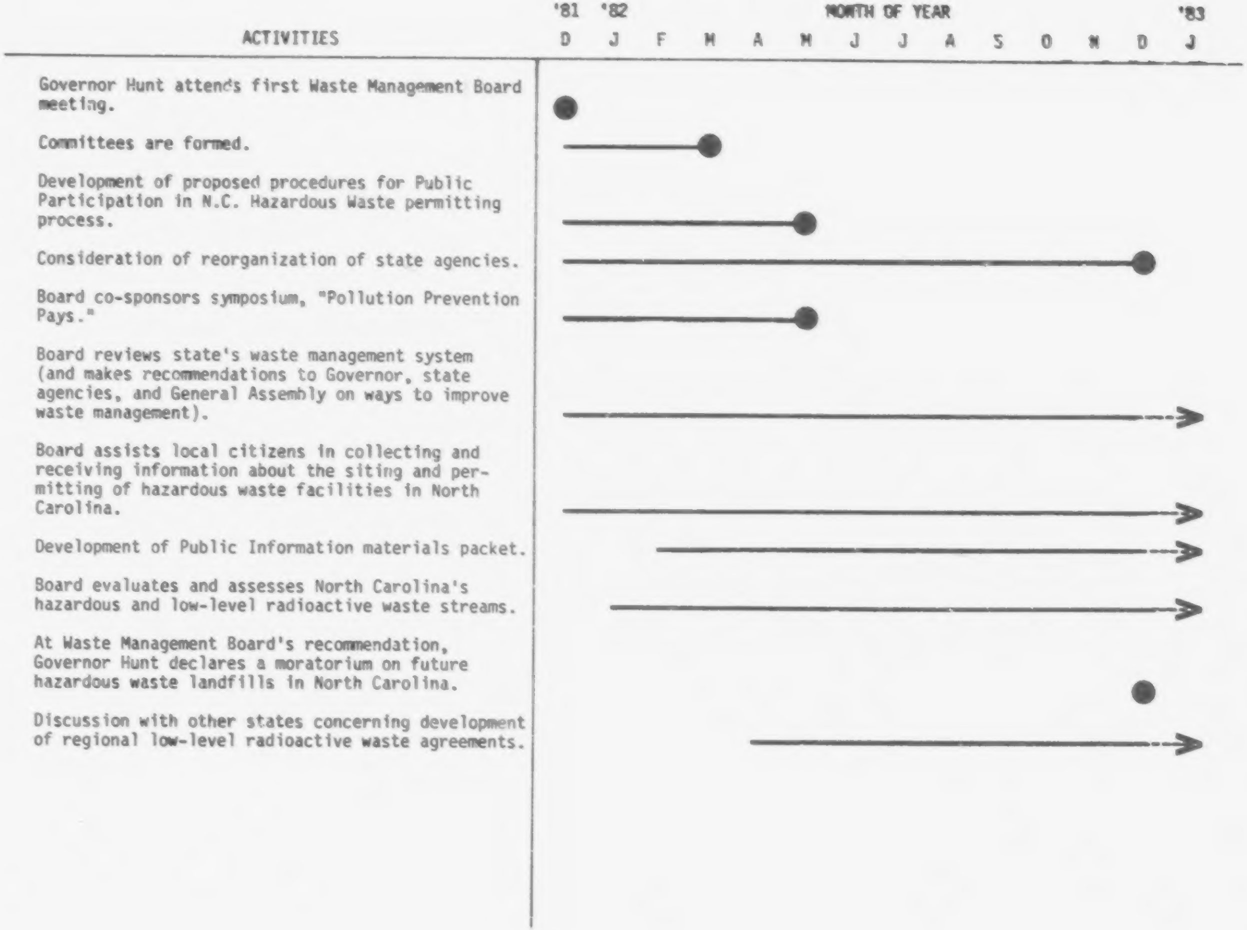
SIXTEEN The Board shall study the development of retrievable, above-ground storage facilities for hazardous wastes.

The major thrust of the Waste Management Board's efforts throughout 1982 has been to study the existing waste management practices and to develop a waste management program for North Carolina. The Waste Management Board feels very strongly that this program must emphasize waste elimination, waste reduction, and waste recycling, thereby ultimately diminishing the volume of waste which requires disposal.

It is because of this preventive focus that the Waste Management Board has not yet made an in-depth study of the development of retrievable, above-ground storage facilities for hazardous wastes. Once the "Analysis of North Carolina's Industrial Waste" is complete, the Board will be better able to determine the volume of hazardous waste which would still require disposal after all known methods of waste prevention or recycling were implemented in North Carolina. The Waste Management Board will then study the development of retrievable, above-ground storage facilities for hazardous waste, and will file a Supplemental Report of its findings and recommendations with the Governor and the General Assembly.

CHAPTER I: ACTIVITIES DURING 1982 CATEGORIZED BY MANDATED FUNCTIONS AND POWERS

PART B: TIME LINE OF ACTIVITIES



ACTIVITIES

Governor Hunt attends first Waste Management Board meeting.

Committees are formed.

Development of proposed procedures for Public Participation in N.C. Hazardous Waste permitting process.

Consideration of reorganization of state agencies.

Board co-sponsors symposium, "Pollution Prevention Pays."

Board reviews state's waste management system (and makes recommendations to Governor, state agencies, and General Assembly on ways to improve waste management).

Board assists local citizens in collecting and receiving information about the siting and permitting of hazardous waste facilities in North Carolina.

Development of Public Information materials packet.

Board evaluates and assesses North Carolina's hazardous and low-level radioactive waste streams.

At Waste Management Board's recommendation, Governor Hunt declares a moratorium on future hazardous waste landfills in North Carolina.

Discussion with other states concerning development of regional low-level radioactive waste agreements.

Development of rules for Limited Preemption Process.

Rules for Limited Preemption Process filed, go into effect.

Development of rules for Privilege License Tax.

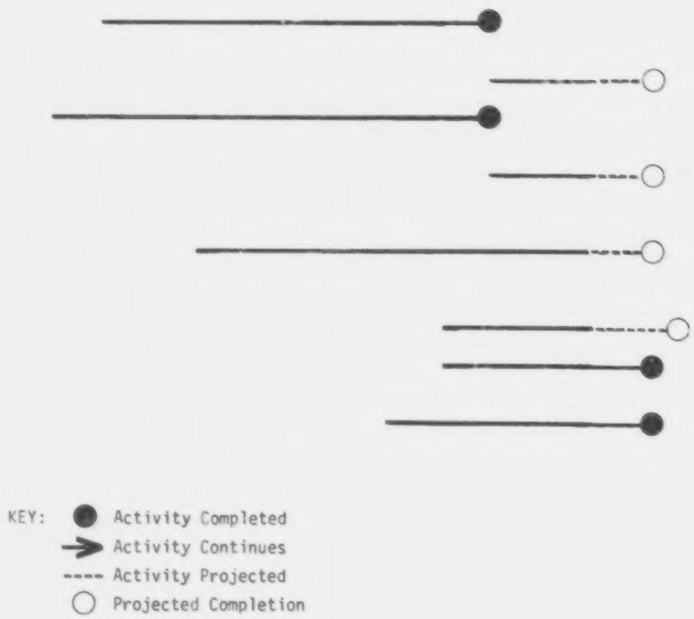
Rules for Privilege License Tax filed, go into effect.

Board studies desirability of establishing by statute a standard of strict liability; report submitted to Governor and General Assembly.

Development of Governor's Award of Excellence selection process; awards recipient recommended to Governor.

Development of Annual Report.

Development of Special Report on reorganization of state agencies.



1958

CHAPTER II: RECOMMENDATIONS FOR ADMINISTRATIVE OR REGULATORY ACTION

PART A: SPECIAL REPORT ON REORGANIZATION OF STATE AGENCIES

1. Introduction

The establishment of the Governor's Waste Management Board was significant in that the General Assembly, acting on recommendations from the Governor's Task Force on Waste Management, recognized the desirability of having the waste problem addressed by a board comprised of North Carolina citizens and state agencies involved in the regulatory program.

While the Board does not have statutory authority to promulgate rules and regulations on hazardous and low-level radioactive waste, the Board is charged with the legal responsibility of reviewing the state's comprehensive waste management system and make recommendations to the Governor, state agencies, and the General Assembly on ways to improve waste management. The Board is also to study and make recommendations on policy issues.

Where changes may be found necessary, the Board will recommend those changes to the affected regulatory commission, i.e., Environmental Management Commission, Commission for Health Services, Radiation Protection Commission, North Carolina Pesticides Board and any others that may exist or be formed.

In order to carry out the responsibilities as outlined above, the Governor's Waste Management Board at its October 27, 1982, meeting adopted unanimously the following policy statement and method of carrying it forth.

2. Policy Statement

a. The Board should request and receive from any state agencies, for its review and comments, proposed changes in state laws or rules of procedure that impact on the management of hazardous and low-level radioactive waste.

b. The Board should review requests for state funds for the management of North Carolina's program.

c. The Board should be an advocate for state agencies before the Advisory Budget Commission and the General Assembly when appropriate, to insure that adequate state funds are available for the management of the program.

d. The Board should be a review agency for requests for funds by departments of State Government from sources other than the state for any program purported to support North Carolina's Waste Management Program.

e. The Board should coordinate the dissemination of information on hazardous waste research that is being conducted by educational institutions in North Carolina.

3. Mechanism

The mechanism for carrying out this newly established Board policy will be the formation of a Waste Management Coordinating Committee under the Governor's Waste Management Board. The formation of this committee will allow an open forum in which problems and concerns on managing hazardous and low level radioactive waste could be addressed on a consistent basis.

4. Committee Composition

The Membership of the Committee will consist of one member from the Commission for Health Services, Environmental Management Commission, Radiation Protection Commission, N.C. Pesticide Board, Secretaries of the Department of Human Resources, Natural Resources and Community Development, the Commissioner of Agriculture and the Governor's Waste Management Board or their designees.

The Secretary of the Department of Human Resources or his/her designee will serve as Chairman of the Coordinating Committee. Support staff will be furnished by the three departments. The staff of the Governor's Waste Management Board will coordinate the work for the committee and see that the tasks are completed.

5. Committee Functions

The functions of this committee will be to: 1) look at long range planning; 2) consider all requests for funds and personnel as they affect waste management; 3) consider and comment on grant applications that affect waste management; 4) consider and make recommendations on administrative or regulatory changes that may be necessary for a more cohesive program; 5) consider proposed regulatory changes recommended by the various commissions as to their interdepartmental impacts; and, 6) any other matters that the Governor's Waste Management Board may ask the committee to consider.

6. Govenor's Waste Management Board Action

All recommendations from this committee will go to the Governor's Waste Management Board for review and final recommendation. The Coordinating Committee will be advisory in nature and will not have statutory authority for promulgating rules and regulations outside of those granted to the individual commissions by law. The meetings of the Coordinating Committee should be scheduled in such a manner as to allow any recommendations that may come from this committee to be presented to the full commissions represented by the committee. The Governor's Waste Management Board will not take any action on recommendations from the Coordinating Committee until comments have been received from the affected commissions and agencies. Those recommendations on changes that may affect city and county governments should be referred to the appropriate organizations to allow for dissemination of this information and the receipt of input on the issue.

7. Conclusion

With the formation of the Committee, the objectives of the General Assembly's intent to have a closely coordinated waste management program can be carried out. This action can be achieved without massive reorganization of departments, which would be extremely costly and could cause delay in implementing the waste management program. The mechanism does exist for bringing the formation of this committee about. Refining the existing system should produce the better product for North Carolina.

The Governor's Waste Management Board recommends this Coordinating Committee in order to enhance and strengthen the present coordination of waste management activities between state agencies and departments.

If the Governor and General Assembly feel that a study of reorganization of all environmental programs be done, funds should be appropriated to the Board for this study or the General Assembly should consider other means of achieving this task.

CHAPTER II: RECOMMENDATIONS FOR ADMINISTRATIVE OR REGULATORY ACTION

PART B: SPECIAL REPORT AND RECOMMENDATIONS ON LIABILITY ISSUES

1. Introduction and Acknowledgements

The Waste Management Act of 1981 created the Governor's Waste Management Board to perform a number of functions relating to the safe management and disposal of hazardous wastes and low-level radioactive wastes in North Carolina. Among these mandated functions is the following:

> The Board shall study and make recommendations on policy issues including but not limited to liability and financial responsibilities within the waste management area. On or before January 1, 1983, the Board shall prepare and present to the Governor and General Assembly a report concerning the desirability of establishing by statute a standard of strict liability for persons involved in storage, transportation, treatment, or disposal of hazardous or low-level radioactive waste in North Carolina.

To carry out this mandate, the Waste Management Board referred the matter to its Legal Committee for study and recommendations. The Legal Committee is chaired by Charles Holt, former State Representative from Cumberland County. In addition to Representative Holt, the Committee is constituted of the two Board members who are members of the legal profession; Heman Clark, former Superior Court Judge and presently Secretary of the North Carolina Department of Crime Control and Public Safety, and William Graham, former member of the North Carolina Court of Appeals and presently Senior Vice President and General Counsel for Carolina Power and Light. The fourth member of the Committee is Melvin Hearn, Deputy Secretary of the North Carolina Department of Agriculture. Glenn Dunn, Attorney with the Solid and Hazardous Waste Management Branch of the North Carolina Department of Human Resources was the Staff Coordinator for the Committee's study.

The composition of the Committee brought an excellent combination of viewpoints to bear on a subject which demands a blend of policy considerations and technical understanding of a complex area of the law. The Committee requested and received valuable assistance from Robert Byrd, Professor of Torts and former Dean of the School of Law at the University of North Carolina at Chapel Hill.

In addition to Professor Byrd's assistance, the Committee benefitted greatly from the viewpoints and expertise of other persons or organizations. The Committee was fortunate to have had available to it since September 1982, a very thorough Report to Congress entitled Injuries and Damages from Hazardous Wastes - Analysis and Improvements of Legal Remedies. This Report is the culmination of a year-long study conducted by a carefully chosen group of lawyers with a variety of viewpoints and considerable expertise. One member of the group that produced the study was George C. Freeman, Jr., of Hunton and Williams, a law firm in Richmond, Virginia, with an extensive environmental law practice. Mr. Freeman, with considerable assistance from Alfred Light, also of the firm, donated much time and expertise to the efforts of the Legal Committee and attended several meetings.

The American Insurance Association, a professional association representing a substantial number of insurance companies, was represented at practically all committee meetings and contributed to consideration of the possible effects of various liability reforms on the insurance industry. The North Carolina Petroleum Council and North Carolina Textile's manufacturers were represented from time to time at the meetings.

With the aid of the above-mentioned persons and groups, the Committee reached its recommendations[1] and presented them to the Waste Management Board at a public meeting held in Raleigh on December 1, 1982. Comments were received at that meeting from the following: John Runkle, Conservation Council of North Carolina; Dan Stroh, North Carolina Sierra Club; Wes Hart, North Carolina CATCH; and Cathy Markatos, Tri-County Alliance.

After considerable discussion, the Board accepted the recommendations set forth in the remainder of this report for presentation to the Governor and General Assembly. These recommendations were made only in regard to hazardous waste. The Governor's Waste Management Board will soon file a Supplemental Report addressing whether or not strict liability should apply to low-level radioactive waste.

2. Recommendations

a. Application of Strict Liability for Injuries Caused by Hazardous Waste

RECOMMENDATION 1 -- The Board recommends that strict liability be applied by statute to any generator, transporter, treater, storer, or disposer of hazardous waste in control of the waste at the time it causes injury to a claimant, and that strict liability on the part of a generator continue while the waste is transported and until it is accepted by a properly licensed treatment, storage, or disposal facility.

---

[1] The Committee's discussion of the liability question, including more thorough descriptions of the issues considered and the reasons for the recommendations, is available in a separate report that may be obtained from the office of the Governor's Waste Management Board.

Imposition of strict liability will help ensure that one of the barriers to meritorious claims, particularly smaller claims, is removed. Strict liability should also cause handlers of hazardous waste to use the greatest possible care to employ practices that minimize the risk of injury.

Transporters are not required under RCRA to carry a certain minimum amount of liability insurance. For this reason, the likelihood that large claims for damages caused by waste in transport could go uncompensated because the transporter has inadequate assets is a serious problem. Continuing generator liability through the transport stage helps overcome this problem. On the other hand, under the recommended approach, a generator's strict liability does not continue indefinitely because it is terminated when the waste is accepted at a permitted and regulated treatment, storage, or disposal facility. Unlike transporters, facility operators are required under RCRA to carry liability insurance, and it is therefore less likely that they will be unable to compensate for damages.

The recommended apportionment of damages where strict liability is applied would be as follows: a person injured by a waste under control of a generator would seek recovery only from the generator under a standard of strict liability; a person injured by waste in the transport stage could seek recovery from the transporter in control of the waste at the time it caused the injury, from the generator, or from both because they would be jointly and severally liable under a standard of strict liability; a person injured by waste at a treatment, storage, or disposal facility could seek recovery only against the owner or operator of the facility under a standard of strict liability.

This approach can be implemented by providing by statute that the person in control of a waste shall be strictly liable for damages caused by that waste; and furthermore a generator of a hazardous waste shall be strictly liable for any damages caused by that waste, except that it shall be an absolute defense if the generator can show that the waste has been properly delivered to and accepted by a treatment, storage and disposal facility properly permitted to receive the waste.

This recommendation blends well with the regulatory program which, among other things, requires that a generator prepare and keep a written "manifest" for any waste shipped by him. The statute could provide that the manifest gives rise to a presumption that the waste was shipped to and accepted by a permitted facility. This presumption would encourage generators to comply with the manifest system.

RECOMMENDATION 2 -- The Board recommends that strict liability apply only to active facilities and ongoing activities.

The existing statutes requiring responsible parties to clean up inactive facilities should be given a chance to succeed in minimizing potential injuries. It is at best harsh, and at worst unconstitutional, to apply statutorily a standard of strict liability for injuries caused by past acts. In such cases the appropriate common law standard should apply.

RECOMMENDATION 3 -- The Board recommends that strict liability apply only for injuries resulting from risks associated with the characteristics that make the waste hazardous.

There is no justification for applying strict liability for injuries caused by the normal activities of a hazardous waste handler if those injuries are not caused by the waste itself. It is, after all, the hazardous nature of the waste that justifies application of strict liability.

RECOMMENDATION 4 -- The Board recommends that a handler of hazardous waste be held strictly liable for all injuries caused by the waste, regardless of whether he knew at the time of injury that the waste could cause that particular type of injury.

This recommendation is consistent with the goal of emphasizing compensation regardless of fault. The Board emphasizes that this does not mean that strict liability will be applied retroactively in the case of a waste that was not considered hazardous at the time of the act that caused the injury. It only applies to an unknown effect from a waste known to be hazardous at the time it causes the injury.

RECOMMENDATION 5 -- The Board recommends that strict liability apply to successors in interest as well as to the generator, transporter, treater, storer or disposer in control of the waste at the time it causes the injury.

This approach would help avoid cases where an injured person is unable to recover damages because the company that created the hazard has passed out of existence or sold a site with a latent hazardous waste problem to another person. In such cases, the new owner may be the only person able to compensate the injured person. Owners of facilities are required to record on the deed that the site has been used as a hazardous waste facility. Therefore, subsequent purchasers should be on notice and have full opportunity to assess the risks they may be acquiring.

RECOMMENDATION 6 -- The Board recommends that punitive damages not be allowed for claims where strict liability is applied.

This recommendation is consistent with the goal of compensating claimants for injuries without consideration of fault on the part of the defendant, and may help avoid extremely large recoveries based on punitive damages that render a defendant financially unable to compensate other injured persons. Sufficient punitive remedies are provided by statute in the form of criminal and administrative penalties for hazardous waste handlers that violate regulations.

RECOMMENDATION 7 -- The Board recommends that although strict liability is imposed, contributory negligence of a claimant will bar any recovery by that claimant.

An injured person should not be able to recover, even where strict liability is imposed, if his own negligent acts are an essential cause of the injury.

b. Statute of Limitations

RECOMMENDATION 8 -- The Board recommends that the statute of limitations begin to run only when the injury becomes apparent or ought to become apparent to an injured person, and that the ten-year statute of repose not apply.

The purpose of statutes of limitations are practical ones: (1) to ensure that legal actions are not initiated so long after the time of the acts alleged to have caused the damage that the facts necessary to litigating the matter have "grown cold" (i.e., are no longer capable of accurate determination), and (2) to ensure that persons are not subjected indefinitely to the threat of liability for past actions.

When strict liability is applied, the first reason becomes less important because there is no need to recall facts relevant to whether the defendant's acts were negligent. The main issue of fact becomes whether the hazardous waste under the control of the defendant caused the injury, an issue based more on scientific data than on facts relating to the defendant's actions. Furthermore, statutes of limitations have no deterrent value and in the case of injuries with long latency periods, they provide a shield for waste handlers.

Commencement of the running of the statute of limitations can be an unfair barrier to recovery for injuries caused by hazardous wastes. Many of the effects of chemical wastes may not manifest themselves for many years (i.e., have long latency periods). This same problem exists in relation to many other types of injuries in our society today. The fairness of statutes of limitation that run from the time of the act of the defendant has been challenged and most states have statutes that run from the time of "discovery" of the injury by the injured party.

North Carolina's statute [N.C.G.S. 1-52(16)] presently provides that an action must be brought within 3 years "from the time that the injury or damage becomes apparent or ought reasonably to have become apparent to the claimant," but then provides an absolute bar, known as a statute of repose, against any action brought "more than 10 years from the last act or omission of the defendant giving rise to the cause of action." Thus, in North Carolina an injured party has three years after the discovery of the injury in which to initiate an action for recovery; however, no action may be brought after ten years under any circumstances.

The goal of facilitating compensation of injured persons outweighs the practical advantages of putting potential legal actions to rest after a certain period of time. This is especially important in cases where the condition causing the damage may develop very slowly (for example, a buried toxic waste may take many years to reach adjacent water supplies) and where the injury from the condition may not manifest itself for many more years.

c. Causation and Related Evidentiary Requirements

RECOMMENDATION 9 -- The Board recommends that there be no attempt to ease the plaintiff's burden of proving that the injury or damage was caused by the hazardous waste handling activity of the defendant.

As the law presently stands, a plaintiff must prove in each case that there is a causal connection between the disease or injury complained of and the hazardous waste related activity of the defendant. Proof of this causal connection is usually difficult in these cases for several reasons.

First, a plaintiff must show the nature of the exposure - whether by inhalation, ingestion or other contact - in order to show the duration, frequency and intensity of exposure. If exposure is adequately proven, proof of causation will usually require large amounts of sophisticated and thus very expensive, medical and scientific testimony to demonstrate the epidemiologic or statistical correlation between the hazardous waste(s) in question and the injury or disease.

Additional problems of proof stem from the fact that there is often a long latency period before effects of exposure become obvious, and during that period the injured party may have been exposed to a wide variety of substances from other sources. Furthermore, a facility alleged to cause the injury may have handled many types of waste which may interact to cause effects that none of them would cause alone, making it more difficult to determine the exact cause of the injury.

Finally, medical science has simply not been able to determine the effects of many chemicals already on the market and, of course, even less will be known at any given time concerning the effects of new chemicals that enter the market constantly.

The difficulties in proving causation have been eased in Workers Compensation Laws by a "rebuttable presumption" approach. Under this approach, if the plaintiff can prove that he suffers from certain types of injuries and that he has had a certain amount of exposure to the substance in question that is known to cause those injuries, the burden shifts to the defendant to prove that the substances within his control did not cause the injury.

This "rebuttable presumption" approach is considered fair because a substantial body of information exits concerning certain substances (for example, asbestos) to show a strong statistical correlation between exposure to the substance and the subsequent development of certain diseases [for example, in the case of asbestos, mesothelioma (lung cancer)]. This is particularly valid and useful in worker's compensation cases because employees are exposed day-in and day-out to a known set of substances.

However, in the case of injuries allegedly stemming from hazardous wastes, the plaintiff will less often be subject to constant exposure over a long period of time and the exposure is likely to be to a greater variety of substances or, for that matter, many unknown substances. This should become even more the case now that strict regulatory programs are in effect which tend to isolate the waste in closely controlled facilities. Thus a presumption of causation in the case of alleged injuries from hazardous waste is probably not as valid or fair as in workplace injury cases. Even in the workplace injury context, however, there have been abuses. For example, Congress in 1981, felt it necessary to abolish several statutory "rebuttable presumptions" in the Black Lung Benefits program because many successful claimants under the program did not have adequate medical evidence of black lung disease.

There is at present insufficient indication that there will be a large number of cases alleging injuries from similar types of wastes, which is the circumstance that justifies a presumption of causation. At present, it seems likely that claims for injuries will involve a wide variety of wastes, and that causation must be verified on a case-by-case basis.

d. Administrative Mechanisms for Determining Liability and Compensating Injured Persons

RECOMMENDATION 10 - The Board does not recommend at this time that an administrative agency be created to adjudicate strict liability in hazardous waste cases.

There are two key factors to consider in deciding whether an agency rather than the courts should adjudicate liability. (1) Will there be enough claims to justify establishing a separate system? and (2) Are the cases likely to be so complicated that special judges or panels are needed to resolve them?

Concerning the first question, there is little actual proof yet that there will be a great increase in toxic tort cases, although it is logical to assume that there will be at least some increase due to the proliferation of chemicals in the last 20-25 years and the typically long time it takes to discover an effect. Furthermore, the implementation of a very stringent regulatory program should reduce the potential for injuries. At this point it seems premature to assume that the case load will justify a separate system.

Concerning the second question, the complexity of these cases will certainly be reduced if strict liability is applied, although the remaining issues of causation are highly technical and the use of administrative law judges with particular expertise might promote more consistent decisions.

The Board concluded that it is premature at this time to assume that the volume or complexity of hazardous waste liability cases will be so great that the general court system cannot handle them adequately.

RECOMMENDATION 11 - The Board does not recommend at this time that a fund be established for compensating injured claimants.

The advantage of a fund is that it would ensure that the money is available to compensate a person with a meritorious claim, that the compensation could be immediate and that identification of a specific responsible party would not be necessary. However, the fact that most of the facilities are required to have liability insurance for precisely this purpose certainly reduces the need for a fund. Furthermore, use of a fund entails some administrative costs that will increase the "transactional" cost that we are trying to avoid.

If compensation is made from a fund rather than by the responsible party, then compensation is divorced from responsibility and has no deterrence value unless the agency administering the fund is empowered to seek recovery from the reponsible person(s). Such a process has potential to increase even further the "transactional" costs. A fund would appear more appropriate in the abandoned or inactive site context, where the identity of a potentially responsible party may be unknown This is the area Congress will be studying closely in connection with the report required by Section 301(e) of the federal Superfund law. California has adopted an "orphan site" fund to compensate those injured by abandoned sites, but that state is apparently the only one which has found such a system necessary.

Furthermore, any attempt to establish a fund would entail difficult problems of deciding who should provide the money for the fund, whereas direct compensation by the responsible defendant places financial responsibility where it should be. Mandatory liability insurance requirements should be adequate to ensure that the defendant will be able to provide compensation in most cases.

CHAPTER II: RECOMMENDATIONS FOR ADMINISTRATIVE OR REGULATORY ACTION

PART C: OTHER RECOMMENDATIONS

In addition to the recommendations outlined within the Special Report on Reorganization of State Agencies and the Special Report on Strict Liability, the Waste Management Board offers the following recommendations for administrative or regulatory action.

RECOMMENDATION 1 -- The Governor's Waste Management Board requests that the General Assembly give to the Solid and Hazardous Waste Management Branch the authority to require annual reports from all generators, transporters, storers and disposers of hazardous waste (1000 kilograms or more) in North Carolina.

On March 15, 1982, the Department of Human Resources, Division of Health Services, Solid and Hazardous Waste Management Branch was notified that the Environmental Protection Agency had postponed its requirement that major generators of hazardous waste file annual reports. Once the Environmental Protection Agency postponed this requirement, the Solid and Hazardous Waste Management Branch could not by North Carolina law require the annual report.

The Governor's Waste Management Board finds the data collected from these annual reports to be most valuable. It is the opinion of the Board that the State should continue to require the annual report for some period of time in order to track its program of managing hazardous and low-level radioactive waste.

RECOMMENDATION 2 -- The Governor's Waste Management Board recommends that sufficient funds be appropriated by the General Assembly for a reasonable regulatory program to protect the health, safety, and environment of the people of North Carolina.

The acceptability of a waste management plan by the people of North Carolina will be primarily based on their beliefs in the state and federal agencies' abilities to protect their health, safety, and their environment. With the continued cutbacks and elimination of federal funds, North Carolina must assume more and more of the financial support of the regulatory and response programs. Statutes for protecting the public health and environment without sufficient personnel and funds to support their mandates will be unacceptable. North Carolina must begin now to look at its budgets for regulatory programs with long range planning in mind to be sure that the program's integrity is maintained.

RECOMMENDATION 3 -- The Governor's Waste Management Board recommends that adequate funding be appropriated by the General Assembly to monitor and clean up old waste sites.

The State regulates, through its permitting procedures, those industries which could produce health threatening situations through accidental discharge of hazardous materials or waste. Even under the most stringent controls and safety measures, accidents will happen and the State must be in a position to respond. A concern voiced often by the public is "if something does happen, what will the State do?" Establishment of guilt before responding to a health threatening situation and searching for funds to clean up the environment is of little comfort to those who are threatened.

The "Oil and Other Hazardous Substances Pollution Fund," General Statute 143-215.87, 215.88, 215.89, 215.90, appears to be the mechanism already in place to house funds for use by North Carolina in responding to clean up. The fund currently has a balance of approximately $33,000. At present, this is the only available source of money with which the State may respond to the need for removal of oil and other hazardous substances and for restoration of areas polluted by discharges of such substances. The fund is not adequate for contingencies which are likely in North Carolina.

If the State enters into a cooperative agreement with EPA to utilize federal Superfund monies for emergency response activities, it will be required to maintain the Pollution Protection Fund as a form of match requirement. If Superfund monies are not available, the State must still be in a financial position to immediately respond to a clean-up and then seek reimbursement, through court action if necessary, from the guilty parties. Money could also be used from this fund to clean up several of the orphan sites that may need some remedial action. G.S. 143-215.87 may require some amendments to be certain that the law allows for the Oil and Other Hazardous Substances Pollution Protection Fund to be spent for cleaning up orphan sites as well as future spills.

APPENDIX A: GLOSSARY

CORROSIVE WASTES	Substances that eat away materials and living tissues by chemical action. They are of particular concern to persons involved in waste hauling and disposal because they can corrode containers and cause leakage. Examples: alkaline cleaners, acid liquids used in etching, and wastes from battery production.
HAZARDOUS WASTES	The Resource Conservation and Recovery Act of 1976, under which hazardous substances are regulated, defines a hazardous waste as "a solid waste or combination of solid wastes, which because of its quantity, concentration or physical, chemical or infectious characteristics may: -- cause or significantly contribute to an increase in mortality or an increase in serious irreversible, or incapacitating reversible illness. -- pose a substantial present or potential hazard to human health or the environment when improperly treated, stored, transported, or disposed of, or otherwise managed." These waste materials can be either solids, liquids, sludges, or contained gases. A hazardous waste has at least one of four characteristics: ignitability, corrosivity, reactivity, or toxicity.
IGNITABLE WASTES	Substances which catch fire easily and as a result normally are segregated from other waste materials. Fires involving hazardous substances not only are dangerous because they generate heat and sometimes toxic smoke, but also because they can spread harmful particles over large areas. Examples: discarded organic solvents, such as toluene and benzene, oils, plasticizers, some pesticides and paint and varnish removers.

LOW-LEVEL RADIOACTIVE WASTES	The Nuclear Regulatory Commission, the federal government agency which regulates the use of commercial radioactive material, defines low-level radioactive wastes as any commercial radioactive waste other than the products from reprocessing used nuclear power plant fuel rods, the by-products of the mining and milling of uranium ore, or certain long-lived radioactive materials which require extremely long periods of isolation from the environment. As their name indicates, low-level radioactive wastes generally contain very low levels of radioactivity. They usually consist of everyday items which have become slightly radioactive through exposure to a radioactive element. Though they present a very small hazard when compared with high-level wastes, low-level radioactive wastes must still be handled carefully and disposed according to strict regulations. Examples: paper, plastic, glassware, disposable syringes, clothing or gloves from medical or research laboratories; or filters, filter sludges, mechanical equipment, piping and liquid wastes from nuclear power plants or industrial operations.
REACTIVE WASTES	Substances which may during routine management react spontaneously, react vigorously with air or water, be unstable to shock or heat, generate toxic gases, or explode. Examples: obsolete munitions and manufacturing wastes from the explosives and chemical industries.
TOXIC WASTES	Any substance (solid, liquid, or gas) that are poisonous to living beings. If they are improperly handled, these wastes or their by-products may be released into the environment and harm human health, particularly through the contamination of ground water. Not all hazardous wastes are toxic, but all toxic wastes are potentially hazardous. Examples: pesticides, arsenic, cadmium, and their salts.

STATE OF NORTH CAROLINA
OFFICE OF THE GOVERNOR
RALEIGH 27611

JAMES B. HUNT, JR.
GOVERNOR

WASTE MANAGEMENT BOARD
March 15, 1982

Mr. Grover Lancaster, Jr., President
NC Association of County Commissioners
Route 1
P.O. Box 412
Vanceboro, North Carolina 28586

Dear Grover:

Thank you for taking time from your busy schedule to meet with the Governor's Waste Management Board on March 3. We sincerely appreciate your offers for help and assistance to the Board as we begin to put together a Waste Management Program in North Carolina.

One of the most important roles of this Board is to insure that correct and proper information is received by the local units of government and by the people who live in our state. Therefore, one of the first suggestions that we would like to discuss with your respective organizations is how you may help encourage the formation of Citizen Involvement Committees on waste management on the local level. Meaningful citizen involvement and participation is critical if an effective waste management system is to be developed in North Carolina.

Waste management facilities, in particular, have met with much suspicion and resistance from citizens due, at least in part, to poor communications between the facility developer, state regulatory agencies, and local citizens. These same problems may occur with existing facilities if proper education and information is not disseminated to local governing bodies and to your citizens who live near existing manufacturing facilities who have a waste stream that may contain some hazardous waste, or an existing company that is a transporter, storer, or processor of hazardous waste. Past experience in other states indicates that early and thorough public participation and education must and should be encouraged.

The Governor's Waste Management Board recommends that local Citizen Involvement Committees on waste management be established. These committees would serve as a forum for exchange of information and opinions between state regulatory agencies and the involved localities. This should provide state agencies with a means for understanding and addressing local concerns. This approach should help avoid misinformation and distrust by educating the citizenry about the rules and regulations that govern the operation of existing facilities and of any new ones that may be proposed.

The formation of Citizen Involvement Committees on waste management is of course optional. Nevertheless, widely based local participation is vital. The Governor's Waste Management Board recommends that committees be organized, and put into operation prior to the permitting of existing or new facilities so that the community will have a good grass roots understanding of what is happening within their own areas and why.

Listed below is a suggested organizational chart for the local citizen committee.

I. Organization

  A. Citizens Organizations
  B. County Government
  C. Municipal Government
  D. Local Industry and Commerce
  E. Local Health and Environmental Agencies or Groups
  F. Local Education and Research Institutions
  G. Local Transportation and Shipping Interest
  H. Agricultural Interest

Nominations should be allowed by anyone from the groups or agencies to be represented. Appointment of the committee should be made by the county commissioners after receipt of these nominations with one commissioner representing county government. Functions of the committee could be, but are not limited to, the following:

1. To meet with the state and private industry to determine the nature and scope of operations of existing facilities and any proposed new facilities that may be under consideration.

2. To participate in planning public meetings, distribution of information and such other steps that should be taken to fully inform all the people of the community about what currently exists or is being proposed, including the advantages and disadvantages.

3. To take steps in conjunction with state and local government and private industry to insure that response is made to questions and concerns of the citizens of the affected areas in so far as available knowledge and understanding permit.

4. To recommend to state and local governments and private industry those measures that should or could be taken to make the location of an existing or new facility acceptable to the citizens.

There may already be in existance, community organizations whose role could be expanded to become a Citizen Involvement Committee on waste management.

The members and staff of the Governor's Waste Management Board stand ready to assist you.

Sincerely,

Buck

Buck O'Shields, Chairman
Governor's Waste Management Board

NORTH CAROLINA ASSOCIATION OF COUNTY COMMISSIONERS

MEMORANDUM

TO: Chairmen and Managers

FROM: Grover Lancaster, Jr.
President

DATE: March 17, 1982

RE: Meeting - Governor's Waste Management Board

On March 3, I met with the Governor's Waste Management Board to discuss with them ways that our Association could be of assistance.

The Governor's Waste Management Board feels that the creation of local Citizen Involvement Committees on waste management will be of great importance in establishing an effective program in North Carolina.

Attached is a letter I received from Buck O'Shields, Chairman of the Governor's Waste Management Board, and I want to share it with you. If you have any questions, please feel free to call Buck at the Waste Management Board Office in Raleigh. It is located on the fifth floor of the Albemarle Building, and the phone number is (919) 733-9020.

MAY 21 1982

Waste Management Board Recommends Local Citizen Involvement

At the recommendation of its Public Participation Subcommittee, chaired by Winston-Salem Alderwoman Virginia Newell, the Governor's Waste Management Board recently adopted a policy statement calling for the establishment of local Citizen Involvement Committees on Waste Management.

The Governor's Waste Management Board, in dealing with the issue of providing for effective citizen involvement in local policy decisions on hazardous waste management, feels that one of its most important roles is to insure that correct and proper information is received by local units of government and by the people who live in our State.

Representatives of the League of Municipalities and the Association of County Commissioners met with the Waste Management Board at its March 3 meeting to discuss this matter prior to the Board action calling for establishment of Citizen Involvement Committees (CIC). Both the League and the Association offered their assistance to the Waste Management Board in public information and education efforts, but urged that actions recommended at the local level be on a voluntary basis.

The Waste Management Board feels that waste management facilities have met with much suspicion and resistance from citizens due, at least in part, to poor communications between the facility developer, state regulatory agencies, and local citizens. These same problems may occur with existing facilities if proper education and information is not disseminated to local governing bodies and to citizens. Past experience in other states indicates that early and thorough public participation and education must and should be encouraged.

The local Citizen Involvement Committees on Waste Management could serve as a forum for exchange of information and opinions between State regulatory agencies and involved localities. This could provide State agencies with an added opportunity for understanding and addressing local concerns. This approach should also help avoid misinformation and distrust by educating the citizenry about the rules and regulations that govern the operation of existing facilities and of any new ones that may be proposed. The Waste Management Board recommends that these committees be organized and put into operation prior to the permitting of existing or new facilities so that the community will have good grass roots understanding what is happening within their own areas and why.

The following interest areas should probably be represented on local CIC's: Citizen Organizations, County Government, Municipal Government, Local Industry and Commerce, Local Health and Environmental Agencies or Groups, Local Education and Research Institutions, Local Transportation and Shipping Interests, and Local Agricultural Interests. The Waste Management Board suggests that county commissioners appoint these local CIC's, although larger or smaller geographic areas could be covered by one CIC.

The functions of local CIC's could include: (1) meeting with State officials and private industry to determine the nature and scope of operations of existing facilities and any proposed new facilities that may be under consideration, (2) to participate in planning public meetings, distribution of information, and other such steps that should be taken to fully inform all the people of the community about what currently exists or is being proposed, including the advantages and disadvantages, (3) to take steps in conjunction with State and local government and private industry to insure that response is made to questions and concerns of the citizens of the affected areas insofar as available knowledge and understanding permit, and (4) to recommend to State and local governments and private industry those measures that should or could be taken to make the location of an existing or new facility acceptable to the citizens.

The Waste Management Board also noted that existing community organizations or groups may want to expand their existing role to become a Citizen Involvement Committee on Waste Management.

Southern City

10 NCAC 48A .0101 through .0111 have been adopted as follows:

SECTION .0100 - RULES OF PROCEDURE FOR IMPLEMENTING THE LIMITED PREEMPTION PROCESS

.0101 PURPOSE

The purpose of these rules is to establish procedures to be used by the Governor's Waste Management Board in reviewing petitions for limited preemption of a local ordinance pursuant to the authority set forth in NCGS 130-166.17B and 104E-6.2.

History Note: Statutory Authority G.S. 143B-216.13 (11) & (14);
Eff. January 1, 1983.

.0102 DEFINITIONS

As used in these rules

(a) "Board" shall mean the Governor's Waste Management Board.

(b) "Chairman" shall mean the Chairman of the Governor's Waste Management Board.

(c) "Developer" means, in the case of a proposed facility, a person who has initiated and paid for plans, investigations, interests in land or made other expenditures preliminary to initiating construction of a facility; or, in the case of a facility in the process of construction, the person with overall responsibility for construction of the facility.

(d) "Facility" shall mean any low-level radioactive waste facility as defined in NCGS 104E-5(9b) and any hazardous waste facility as defined in NCGS 130-166.16(5).

(e) "Operator" means the person responsible for the overall operation of a facility.

(f) "Party" means the person who submits a petition and the city or county that adopted the ordinance(s) that is the subject of the petition.

(g) "Person" means an individual, corporation, company, association, partnership, unit of local government, state agency, federal agency, or other legal entity.

History Note: Statutory Authority G.S. 143B-216.13 (11) & (14);
Eff. January 1, 1983.

.0103 STANDING TO PETITION THE BOARD

The developer or operator of a facility that would be prevented from construction or operation by a county, municipal or other local ordinance(s) may petition the Board to review the local ordinance(s) according to these procedures. The facility may be proposed, under construction, or completed at the time of the appeal. In order for a facility to be "proposed," it must be shown that the developer has a real interest in construction or operation of a facility in the jurisdiction to which the ordinance(s) in question applied. Such a real interest shall be shown by:

(a) Possession of printed plans for a facility at a specific site in the jurisdiction, and;

(b) Significant expenditures of money for technical investigation of a site or sites in the jurisdiction, and;

(c) Possession of land, options to purchase land, or some other contractual agreement evidencing an interest in land for a potential site.

History Note: Statutory Authority G.S. 143B-216.13 (11) & (14);
Eff. January 1, 1983.

.0104 GROUNDS FOR PETITION

(a) The grounds for petitioning the Board to review a local ordinance(s) are that a facility would be prevented from construction or operation by the ordinance(s) in question. In order to show that a facility would be prevented from construction or operation, the petitioner must show that:

(1) The facility has been denied, pursuant to the ordinance, any legally required permit, license, certification or other form of permission to initiate or continue construction or operation of the facility; provided, however, that the petitioner must show that he/she has exhausted any appeal procedures provided by the ordinance(s), or that despite his/her good faith efforts to appeal as provided by such ordinance(s), the county has been responsible for such unreasonable delay as to effectively constitute denial, or;

(2) Any legally required permit, license, cetficiation or other form of permission to initiate or continue construction or operation of the facility has been granted with conditions that in effect prevent construction or operation, or;

(3) Any legally required permit, license, certification or other form of permission to initiate or continue construction or operation of the facility has been withheld for an unreasonable time so as to constitute denial, or;

(4) The ordinance(s) in question as written and adopted would necessarily prevent the facility from initiating construction or from operating.

(b) For the purposes of this rule, an ordinance may be considered to prevent construction or operation if compliance with it is so economically burdensome beyond what is necessary to protect the public, health and safety as to make it clearly impracticable for the facility to compete with similar facilities.

History Note: Statutory Authority G.S. 143B-216.13 (11) & (14);
Eff. January 1, 1983.

.0105 NOTICE OF PETITION

A notice of petition shall be in writing, shall describe the petitioner's interest in the matter, and shall set forth clearly the grounds for the petition. The notice of petition shall be mailed to the Governor's Waste Management Board, Department of Human Resources, P.O. Box 2091, Raleigh, NC 27602.

History Note: Statutory Authority G.S. 143B-216.13 (11) & (14);
Eff. January 1, 1983.

.0106 RESPONSE TO NOTICE OF PETITION

(a) A notice of petition to the Board will be acknowledged in writing. A copy of the letter of acknowledgement will also be sent to the Chairman of the Board of Commissioners or the mayor of the city that adopted the ordinance(s) in question.

(b) Along with the acknowledgement of the petition the Board shall request from the petitioner such information and arguments relevant to the petitioner's standing to petition as defined in .0103 of these rules and to the grounds for appeal set forth in .0104 of these rules as it deems necessary to complete the petition. The Board shall specify a date before the public hearing concerning the matter by which the requested information and arguments must be received by the Board. The Board, at its discretion, may refuse the petition as incomplete if it finds that the petitioner has failed to comply substantially with the request for information relating to standing and grounds for the appeal, or to show cause why compliance is unduly burdensome.

(c) The Board may also request from the petitioner or the city or county any information and arguments relevant to the findings set forth in .0109 that the petitioner or the city or county desires the Board to consider in making its recommendations to the Governor. The requested information concerning the findings is not mandatory and no party shall be prejudiced for failing to provide such information.

Both the petitioner and the city or county shall be notified of any request made pursuant to this paragraph.

(d) Nothing in this rule shall prevent the petitioner from modifying or providing additional information and arguments at the hearing or in any other appropriate manner before the Governor's final decision is made.

(e) Upon receiving the information and arguments requested from the petitioner, the Board shall transmit it to the city or county and shall inform the city or county that an answer may be filed at anytime before the final decision of the Governor is made.

History Note: Statutory Authority G.S. 143B-216.13 (11) & (14);
Eff. January 1, 1983.

.0107 PUBLIC HEARING TO BE HELD

(a) When a petition is filed with the Governor's Waste Management Board, the Board shall hold a public hearing to consider the petition. The hearing shall be held in the affected locality in accordance with G.S. 150A, Article 2, within a reasonable time but not more than 45 days time requirement for good cause.

(b) The Board shall publish notice of the hearing twice a week for two successive weeks in a newspaper of general circulation in the county where the proposed site is located. The final notice shall appear at least 15 days but not more than 25 days before the hearing date. The notice shall include:

(1) A reference to the statutory authority under which the petition is filed and the hearing is being held;
(2) The time and place of the public hearing and a statement of the manner in which data, views and arguments may be submitted by any interested person to the Board either at the hearing or at other times;
(3) A summary statement of the subject matter of the hearing.

History Note: Statutory Authority G.S. 143B-216.13 (11) & (14);
Eff. January 1, 1983.

.0108 CONDUCT OF THE HEARING

(a) Any interested person may appear before the Board at the hearing to offer testimony. In addition to testimony before the Board, any interested person may submit written material to the Board for its consideration.

(b) The Board may, in its discretion, place reasonable time limits on the testimony of each interested person who appears before the Board at the hearing.

(c) Members of the Board may ask questions of any person who appears before the Board at the hearing.

(d) The Board shall hold the record open to receive written comments from interested persons for 15 days after termination of the hearing.

History Note: Statutory Authority G.S. 143B-216.13 (11) & (14);
Eff. January 1, 1983.

.0109 THE BOARD's RECOMMENDATIONS TO THE GOVERNOR

(a) No later than 60 days after the hearing, the Board shall present its written recommendations to the Governor to approve or disapprove the facility.

Before recommending that the Governor approve the facility, the Board must make the following findings:

(1) That the proposed facility is needed in order to establish adequate capability for the management of hazardous waste generated in North Carolina and therefore serves the interests of the citizens of the State as a whole;
(2) That all legally required State and federal permits or approvals have been issued by the appropriate State and federal agencies;
(3) That local citizens and elected officials have had adequate opportunity to participate in the siting process;
(4) That the construction and operation of the facility will not pose an unreasonable health or environmental risk to the surrounding locality and that the facility developer or operator has taken or consented to take any reasonable measures to avoid or manage foreseeable risks and to comply to the maximum feasible extent with any applicable ordinance(s).

(b) The Board's recommendation shall include a complete transcript of the hearing, all written material presented to the Board regarding the site location and the four specific findings set forth in (a) above, and any minority positions on the recommendation and the four specific findings.

(c) The Board's decision as to its recommendation shall be made by concurrence of a majority of the Board members. To be eligible to vote, a Board member shall be present at the time the vote is taken.

History Note: Statutory Authority G.S. 143B-216.13 (11) & (14);
Eff. January 1, 1983.

.0110 GOVERNOR'S DECISION

(a) The Governor's decision shall be issued by transmittal to the petitioner and town or county within a reasonable time following receipt of the Board's recommendation.

(b) The Governor's decision shall be in writing and shall identify the material submitted to him by the Board plus any additional materials used in arriving at his decision. The decision shall affirm or disaffirm the findings of the Board and may set forth additional findings. The decision shall state whether the Governor approves or disapproves the establishment or operation of the facility. If the Governor makes the four findings set forth in .0109 (a) of these rules, he shall approve the facility. If the Governor does not make all four findings, he shall disapprove the facility.

History Note: Statutory Authority G.S. 143B-216.13 (11) & (14);
Eff. January 1, 1983.

.0111 APPEAL OF THE GOVERNOR'S DECISION

(a) The decision of the Governor shall be final unless a party shall file pursuant to G.S. 7A-29 a written appeal within 30 days of such decision.

(b) The record on appeal shall include all materials and information submitted to or considered by the Governor in accordance with G.S. 130-166.17B (c) and these rules. The scope of judicial review shall be limited to questions of abuse of discretion.

History Note: Statutory Authority G.S. 143B-216.13 (11) & (14);
Eff. January 1, 1983.

10 NCAC 48B .0101 through .0112 have been adopted as follows:

SECTION .0100 - RULES OF PROCEDURE FOR IMPLEMENTING PRIVILEGE LICENSE TAX APPEAL

.0101 PURPOSE

The purpose of this Section is to set forth the rules of practice for appeals to the Governor's Waste Management Board by any person or firm upon which a privilege license tax is levied pursuant to G.S. 160A-211.1 or G.S. 153A-152.1.

History Note: Statutory Authority G.S. 143B-216.13(12) and (14)
Eff. January 1, 1983

.0102 DEFINITIONS

As used in these rules

(a) "Hearing" shall mean a contested case hearing as provided in G.S. 150A-23(a).

(b) "Board" shall mean the Governor's Waste Management Board.

(c) "Chairman" shall mean the Chairman of the Governor's Waste Management Board.

(d) "Facility" shall mean any low-level radioactive waste facility as defined in NCGS 104E-5(9b) and any hazardous waste facility as defined in NCGS 130-166.16(5).

(e) "Hearing Panel" shall mean any group of members of the Board appointed by the Chairman and delegated by him the authority to hear an appeal.

(f) "Hearing Officer" shall mean any person to whom the Chairman delegates authority to hear an appeal.

History Note: Statutory Authority G.S. 143B-216.13(12) and (14)
Eff. January 1, 1983

.0103 WHO MAY APPEAL

(a) Any person or firm operating a facility taxed pursuant to G.S. 160A-211.1 or G.S. 153A-152.1 may appeal the tax rate to the Board, but shall pay the tax when due, subject to a refund when the appeal is resolved by the Board or in the Courts.

(b) No person shall appeal to the Board pursuant to these procedures unless any appeal procedure provided by local ordinance has been exhausted, or a good faith effort has been made to appeal, but the local government has failed to take timely action such that the operation or construction of the facility may be prohibited.

History Note: Statutory Authority G.S. 143B-216.13(12) and (14)
Eff. January 1, 1983

.0104 GROUNDS FOR APPEAL

Grounds for appealing the tax rate shall be that the amount of the tax does not meet the requirements of 160A-211.1(b) in case of a city tax or G.S. 153A-152.1 in the case of a county tax.

History Note: Statutory Authority G.S. 143B-216.13(12) and (14)
Eff. January 1, 1983

.0105 NOTICE OF APPEAL

Appeals of a tax rate shall be filed no later than 30 days after the levy of the tax in the case of a facility subject to the tax at the time of the levy, or no later than 30 days after notice that the tax is due in the case of a facility not subject to the tax at the time of the levy. An appeal shall be in writing and shall be mailed to the Governor's Waste Management Board, Department of Human Resources, P.O. Box 2091, Raleigh, NC 27602. The appellant shall cause a copy of the notice of appeal to be served upon the city or town levying the tax in question.

History Note: Statutory Authority G.S. 143B-216.13(12) and (14)
Eff. January 1, 1983

.0106 RESPONSE TO NOTICE OF APPEAL

(a) Notice of appeal to the Board will be acknowledged in writing and a form requesting information necessary to perfect the appeal will be mailed to the appellant along with the acknowledgement. A copy of the letter of acknowledgement will also be sent to the Chairman of the Board of Commissioners and the attorney for the county, in the case of an appeal of a county tax, or the Mayor and attorney for the city in the case of an appeal of a city tax.

(b) Unless an extension is requested and granted, the requested information necessary to perfect the appeal must be returned within 30 days of the date the appellant receives the letter of acknowledgement or the appeal will be dismissed. The applicant shall send a copy of the requested information to the city or county attorney at the same time it is returned to the Board.

(c) The acknowledgement will also transmit a date for hearing the appeal to be set by the Chairman. The date of the hearing shall be within 90 days of receipt of the notice of appeal, except that at the discretion of the Chairman, the date may be extended for good cause.

History Note: Statutory Authority G.S. 143B-216.13(12) and (14)
Eff. January 1, 1983

.0107 FILING OF AN ANSWER

(a) The city or county that levied the tax being appealed shall file an answer within 20 days from receipt of the completed application, and shall send a copy of the answer to the appellant at the same time it is filed with the Board.

(b) The city or county's failure to an answer shall not constitute waiver of the city or county's rights nor an admission of the appellant's allegations.

History Note: Statutory Authority G.S. 143B-216.13(12) and (14)
Eff. January 1, 1983

.0108 DOCUMENTS TO BE SUBMITTED BEFORE HEARING

(a) At least 10 days prior to the date of the hearing, each party to the appeal shall furnish to the Board a copy of all documents to be introduced at the hearing, including maps, pictures, facility descriptions and briefs, and shall also submit the names of any witnesses that they plan to call to testify at the hearing. This requirement may be modified by the Board if it is shown that compliance would cause unduc hardship on one or both of the parties, provided that any such modification and the reasons for it be set out in writing.

(b) In the absence of an agreement to the contrary, a copy of each such document and a list of the names of witnesses shall also be furnished or made available to the opposing party at the same time.

History Note: Statutory Authority G.S. 143B-216.13(12) and (14)
Eff. January 1, 1983

.0109 WHO SHALL CONDUCT A HEARING

The Chairman shall determine for each panel whether the matter should be heard by the full Board, a panel of Board members, or a hearing officer, and shall notify the parties of the determination. The Chairman is hereby authorized to appoint Board members to a panel or a hearing officer and to delegate to the panel or hearing officer authority to hear an appeal for the Board.

History Note: Statutory Authority G.S. 143B-216.13(12) and (14)
Eff. January 1, 1983

.0110 RULES FOR CONDUCTING THE HEARING

The following rules of the Department of Human Resources for contested cases set forth in 10NCAC .01B.0200 are hereby adopted, except that when used for the purpose of appeals of privilege license taxes under this section, the term "hearing office" shall mean the Office of the Governor's Waste Management Board and the term "Presiding Officer" shall mean the hearing officer or head of a hearing panel who has been appointed by the Chairman.

(a) 10NCAC .01B.0207 Waiver of Hearing
(b) 10NCAC .01B.0208 Intervention
(c) 10NCAC .01B.0209 Written Answer
(d) 10NCAC .01B.0210 Venue
(e) 10NCAC .01B.0211 Discovery

.0111 PROPOSAL FOR DECISION

(a) If the appeal is heard by a hearing officer or a panel composed of less than a majority of the Board members, the decision shall not be made until a proposal for decision is served on the parties, and an opportunity is given to each party to file exceptions and proposed findings of fact and to present oral and written arguments to the Board.

(b) A proposal for decision shall contain proposed findings of fact and proposed conclusions of law, and shall be prepared by a person who conducted the hearing unless he becomes unavailable to the Board. If no such person is available, the proposal may be prepared by one who has read the record, unless demeanor of witnesses is a factor. If demeanor is a factor, the portions of the hearing involving demeanor shall be held again, or the case shall be dismissed without prejudice.

(c) The parties, by written stipulation or at the hearing, may waive compliance with this rule.

History Note: Statutory Authority G.S. 143B-216.13(12) and (14)
Eff. January 1, 1983

.0112 FINAL DECISION

(a) No final decisions as to whether the amount of the tax meets the requirements of G.S. 160A-211.1(b) or G.S. 153A-152.1 shall be made unless a majority of the Board members is eligible to vote.

(b) To be eligible to vote, a member shall:

(1) be present at the hearing, or, if the appeal was heard by a panel or hearing officer, at the oral presentation by the parties and the hearing officer or hearing panel; and

(2) be present at the time the vote is taken.

(c) If the entire Board hears an appeal, a final decision may be made at the close of the hearing or the Board may defer the decision until some future date to be determined at the discretion of the Board. If the final decision is deferred, the Board may require each party to prepare and submit to it a proposal for decision.

(d) A final decision shall be made by concurrence of a majority of the Board members eligible to vote.

ACKNOWLEDGEMENTS

The Governor's Waste Management Board wishes to express its appreciation to the members of the two Technical Advisory Committees who contributed their time and expertise providing valuable background information to the Technical Committee.

TECHNICAL ADVISORY COMMITTEE ON HAZARDOUS WASTE

Dr. J. K. Ferrell, Chairman
Chemical Engineering Department
North Carolina State University

(Van) Evander H. Rowell
North Carolina Textile Manufacturing Association
Fieldcrest Mills

Dr. Donald Hart
Chemical Industry Institute of Toxicology

Dr. Alvis Turner
School of Public Health
Sanitary Engineering
University of North Carolina - Chapel Hill

C. Edward Scott, III
Engineering Support Service
R. J. Reynolds Tobacco Company

Steve Conrad
Natural Resources & Community Development
Division of Land Resources

Bill Parks
Drexel Heritage Engineering Center

Charles F. Grainger
Grainger Laboratories

TECHNICAL ADVISORY COMMITTEE ON LOW-LEVEL RADIOACTIVE WASTE

Captain Bill Briner, Chairman
Duke University Medical Center
Department of Radiology

Dayne Brown
Department of Human Resources - Facility Services
Radiation Protection Section

James M. Davis, Jr.
Carolina Power & Light
Fuel & Materials Management

Dr. Ralph L. Ely, Jr.
Research Triangle Institute
Office of University Relations

Lionel Lewis
Duke Power
System Health Physicist

Dr. Raymond L. Murray
Professional Engineers of North Carolina
North Carolina State University

William B. Smalley
General Electric Company

Dr. James E. Watson
School of Public Health
Department of Environmental Sciences & Engineering
University of North Carolina - Chapel Hill

Dr. Richard Witcofski
Bowman-Gray School of Medicine

The Waste Management Board wishes to express its special thanks to individuals who were not members of the Board who volunteered their time to serve as advisory members of the Public Information/Participation Committee. Their efforts were extremely valuable in developing ways to educate and involve citizens in the formulation of an acceptable waste management program for North Carolina.

Jean Vollrath-Vaughn
June Kimmel
Russ Edmonston
Karen Fox

The Waste Management Board would like to express their appreciation to the following individuals and state agencies for their advice and cooperation on the various projects undertaken by the Board in 1982.

Department of Human Resources:	Secretary Dr. Sarah Morrow, Lucy Bode, Jim Woodall, Charles Davis, Tom Jones, Dr. Ronald Levine, O. W. Strickland, Emil Breckling, Bill Meyer
Department of Natural Resources and Community Development:	Secretary Joe Grimsley, Jim Summers, Bob Helms, Billy Ray Hall
Department of Administration:	Secretary Jane Patterson
Department of Commerce:	Secretary D. M. Faircloth
Department of Agriculture:	Commissioner James A. Graham
Department of Crime Control and Public Safety:	Secretary Heman Clark
Department of Public Education:	State Superintendent Craig Phillips
Department of Transportation:	Secretary William Roberson, Jr.

North Carolina State University

East Carolina University

University of North Carolina - Chapel Hill

Duke University

Robert Jansen, Senior Policy Advisor, Office of the Governor

Dr. Quentin Lindsey, Science & Public Policy Advisor, Office of the Governor

Dr. Don Huisingh

Sam Johnson, Attorney

Jerry Roberts, North Carolina Textile Manufacturers Association

The Waste Management Board would like to express special thanks to Bryant Haskins and Glenn Dunn of the Department of Human Resources for their valuable staff assistance.

The Waste Management Board wishes to acknowledge with gratitute the highly valuable information provided by the following organizations who presented different perspectives on the waste management problem. They all volunteered their time in preparing and delivering their comments and presentations to the Waste Management Board.

Sierra Club
Conservation Council of North Carolina
Tri-County Alliance
North Carolina CATCH
Anson County CACTUS
Anson County Waste Management Board
League of Women Voters

The Waste Management Board would also like to express their appreciation to the many members of the public and news media who attended meetings and volunteered their opinions regarding matters facing the Board. These expressions of opinion continue to reinforce in the minds of the Waste Management Board members their responsibility to serve the interest of the general public.

A very special thank you to the staff of the Governor's Waste Management Board for their dedication and professionalism in carrying out their assigned tasks on behalf of the Board and in the preparation of this report.

Angie Woodall, Administrative Assistant to the Chairman/Director
Kathy Visocki, Community Relations Coordinator
Doris Wilson, Secretary
Cecil Cross, Summer Intern
Kathy Groze, Word Processor

GENERAL ASSEMBLY OF NORTH CAROLINA
SESSION 1983

2

HOUSE BILL 738
Committee Substitute Favorable 7/8/83

Short Title: Strict Liab. Hazardous Wastes. (Public)

Sponsors: Representative

Referred to: Water & Air Resources.

April 7, 1983

A BILL TO BE ENTITLED

AN ACT TO PROVIDE FOR STRICT LIABILITY FOR DAMAGES RESULTING FROM HAZARDOUS WASTES IN NORTH CAROLINA.

The General Assembly of North Carolina enacts:

Section 1. Short title. This act may be referred to as the Hazardous Waste Strict Liability Act of 1983.

Sec. 2. Purpose. The purpose of this act is to provide for a workable strict liability system for hazardous wastes in North Carolina as recommended in the 1983 Report of the Governor's Waste Management Board.

Sec. 3. Creation of a strict liability system for hazardous wastes. Chapter 130 of the General Statutes as it appears in Volume 3B of the General Statutes (and the Cumulative Supplement thereto) is amended:

(1) By adding the following at the end of G.S. 130-166.16:

"(23) 'Claimant' means a person damaged by a hazardous waste occurrence.

"(24) 'Hazardous waste occurrence' means any sudden or non-sudden occurrence in which damages result from any quality or characteristic of a solid waste, as defined in G.S. 130-166.16(16), which quality or characteristic causes the waste to be a hazardous waste under this Article and the rules and regulations adopted pursuant to it.

"(25) 'Strictly liable' means liable without regard to the defendant's negligence or fault. The defendant's foreseeability of danger or risk arising from or injury or other consequences caused by a hazardous quality or characteristic of the waste either at or prior to the occurrence shall not be relevant to a determination of liability.

"(26) 'Caused by' means caused in fact. If the evidence offered by any party tends to show that the damage of which the claimant complains was caused by both a hazardous waste occurrence and other causes, liability under G.S. 130-166.21G shall be limited to damages attributable to the hazardous waste occurrence."

(2) By adding a new section G.S. 130-166.21G to read as follows:

"§ 130-166.21G. Hazardous waste liability.--(a) This section applies only to hazardous waste occurrences caused wholly or partially by a defendant's operations or activities occurring after the effective date of this act. For the purpose of this section, waste polychlorinated biphenyls shall be considered a hazardous waste. Furthermore, for the purposes of this section, governmental immunity from strict liability for bodily injury or property damage caused by a hazardous waste occurrence is hereby waived, but only to the extent that damages do not exceed the amount of damages authorized by the North Carolina Tort Claims Act, G.S. 143-291. Any agency of the State of North Carolina that generates, transports, treats, stores, or disposes of hazardous waste is hereby authorized and empowered to procure proper insurance against such liability..

(b)

(1) Subject only to the defenses set forth in subsections (c) and (e) of this section, the generator, transporter, treater, storer or disposer in control of a hazardous waste at the time of a hazardous waste occurrence shall be strictly liable for bodily injury or property damage caused by the occurrence.

(2) Subject only to the defenses set forth in subsections (c) and (e) of this section, the generator of a hazardous waste, whether or not in control of the hazardous waste at the time of an occurrence, shall be strictly liable for bodily injury or property damage caused by hazardous waste occurrences arising from the hazardous waste generated. Under this subdivision, the generator shall be jointly and severally liable together with the transporter or any other person in control of the hazardous waste at the time of the occurrence. For purposes of this subsection, any person that accepts a hazardous waste from a transporter for storage and causes the hazardous waste to be again

transported shall be considered a generator.

(c) There shall be no liability under subsection (b) for a person otherwise liable who can establish by a preponderance of the evidence:

(1) that the claimant had knowledge of the danger and voluntarily and unreasonably encountered that danger; or

(2) that the hazardous waste occurrence was caused solely by any one of the following:

(i) an act of God;

(ii) an act of war or sabotage; or

(iii) an intentional act or omission of a third party (but this defense shall not be available if the act or ommission is that of an employee or agent of the defendant, or if the act or omission occurs in connection with a contractual relationship with the defendant).

(d) Nothing in this section shall bar or otherwise affect the transfer of liability to the Post Closure Liability Fund, under Section 232 of the Federal Comprehensive Environmental Response, Compensation and Liability Act of 1980.

(e)

(1) Subject to the provisions of subsection (i), any defendant who proves that hazardous waste was transferred to and accepted by a hazardous waste facility duly permitted by appropriate regulatory agencies of which he is not the beneficial owner or

operator and that such transfer and acceptance is in compliance with applicable federal and State requirements existing at the time of the transfer and acceptance shall not be liable under subsection (b) for bodily injury or property damage caused by a hazardous waste occurrence after such transfer and acceptance.

(2) When signatures are admitted and established, production of a copy of a hazardous waste manifest entitles a defendant, who according to the manifest generated or transported the waste to a hazardous waste facility, to the defense under this subsection unless the claimant establishes that the waste was not in fact transferred to and accepted by the hazardous waste facility prior to the hazardous waste occurrence.

(3) Each signature on a hazardous waste manifest is presumed to be genuine or authorized unless the party opposing its admission offers prima facie evidence that it is not genuine or authorized.

(f) No punitive or exemplary damages shall be awarded in any action under subsection (b).

(g) Nothing in this section shall deprive a claimant from electing to pursue any other cause of action based upon a hazardous waste occurrence that may exist under statutory or common law, or to deprive a person liable under subsection (b) of any right of contribution or indemnity he may have under law in existence at the time of the occurrence, nor shall anything in this section restrict any right which any person (or class of persons) may have under any statute or common law to seek enforcement of any standard or requirement or to seek the imposition by any State and federal authorities of civil and criminal sanctions. If the principal action was decided on the basis of strict liability, the principles of strict liability shall also apply in any action for contribution or indemnification arising out of the same hazardous waste occurrence.

(h) If any provision of this section or its application to any person or circumstances is held invalid by any court of competent jurisdiction, the invalidity will not affect other provisions or applications that can be given effect without the invalid provision or application; and to this end the provisions of this act are severable."

Sec. 4. G.S. 1-52(16) is amended by changing the second sentence to read as follows:

"Provided that no cause of action shall accrue more than 10 years from the last act or omission of the defendant giving rise to the cause of action; except that for any cause of action arising out of a hazardous waste occurrence as defined in G.S. 130-166.16(24) no cause of action based on strict liability shall accrue more than 30 years from the last act or omission of the defendant giving rise to the cause of action."

Sec. 5. This act shall become effective October 1, 1983.

CALIFORNIA

S Records §§ 35, 41.

55. Alcohol and drug abuse records; communicable disease carriers

Nothing in this chapter shall require a health care provider to permit inspection or provide
of alcohol and drug abuse records where, or in a manner, prohibited by Section 408 of the
d Drug Abuse Office and Treatment Act of 1972 (Public Law 92-255) or Section 338 of the
d Comprehensive Alcohol Abuse and Alcoholism Prevention, Treatment, and Rehabilitation Act
70 (Public Law 91-616), or by regulations adopted pursuant thereto. Alcohol and drug abuse
is subject to such federal laws shall also be subject to the provisions of this chapter, to the extent
such federal laws do not prohibit disclosure of the records. All other alcohol and drug abuse
ls shall be fully subject to the provisions of this chapter.

Nothing in this chapter shall require a health care provider to permit inspection or provide
of records or portions of records where or in a manner prohibited by existing law respecting the
lentiality of information regarding communicable disease carriers.

ords ⟸54.
S. Records § 36.

56. Summary of record; preparation; time of delivery; contents; fee

A health care provider may prepare a summary of the record, according to the requirements of
ection, for inspection and copying by a patient. If the health care provider chooses to prepare
a summary of the record rather than allowing access to the entire record, he or she shall make
a summary of the record available to the patient within 10 working days from the date of the
nt's request. However, if more time is needed because the record is of extraordinary length or
se the patient was discharged from a licensed health facility within the last 10 days, the health
provider shall notify the patient of this fact and the date that the summary will be completed,
n no case shall more than 30 days elapse between the request by the patient and the delivery of
immary. In preparing the summary of the record the health care provider shall not be obligated
lude information which is not contained in the original record.

A health care provider may confer with the patient in an attempt to clarify the patient's
se and goal in obtaining his or her record. If as a consequence the patient requests information
only certain injuries, illnesses, or episodes, nothing in this subdivision shall require the provider
pare the summary required by this subdivision for other than the injuries, illnesses, or episodes
quested by the patient. The summary shall contain for each injury, illness, or episode any
nation included in the record relative to the following:

Chief complaint or complaints including pertinent history.

Findings from consultations and referrals to other health care providers.

Diagnosis, where determined.

Treatment plan and regimen including medications prescribed.

Progress of the treatment.

Prognosis including significant continuing problems or conditions.

Pertinent reports of diagnostic procedures and tests and all discharge summaries.

Objective findings from the most recent physical examination, such as blood pressure, weight,
ctual values from routine laboratory tests.

Nothing in this section is to be construed as requiring any medical records to be written or
tained in any manner not otherwise required by law.

The summary shall contain a list of all current medications prescribed, including dosage, and any
ivities or allergies to medications recorded by the provider.

The provisions of subdivision (c) of Section 25252 shall be applicable whether or not the health
provider elects to prepare a summary of the record.

(f) The health care provider may charge no more than a reasonable fee based on actual time and cost for the preparation of the summary. The cost shall be based on a computation of the actual time spent preparing the summary for availability to the patient or the patient's representative. It is the intent of the Legislature that summaries of the records be made available at the lowest possible cost to the patient.

C.J.S. Records § 36.

§ 25257. Law governing; Confidentiality of Medical Information Act; Insurance Information and Privacy Protection Act; Information Practices Act of 1977

Except as otherwise provided by law, nothing in this chapter shall be construed to grant greater access to individual patient records by any person, firm, association, organization, partnership, business trust, company, corporation, or municipal or other public corporation, or government officer or agency. Therefore, the provisions of this chapter do not do any of the following:

(a) Relieve employers of the requirements of the Confidentiality of Medical Information Act (Part 2.6 (commencing with Section 56) of Division 1 of the Civil Code).

(b) Relieve any person subject to the provisions of the Insurance Information and Privacy Protection Act (Article 6.6 (commencing with Section 791) of Chapter 1 of Part 2 of Division 1 of the Insurance Code) from the requirements of that act.

(c) Relieve government agencies of the requirements of the Information Practices Act of 1977 (Title 1.8 (commencing with Section 1798) of Part 4 of Division 3 of the Civil Code).

(Added by Stats.1982, c. 15, p. —, § 1.)

Hazardous substance as governed by definitions contained in this chapter, see Revenue and Taxation Code § 43002.

Law Review Commentaries

Hazardous substance account, hazardous Substance Tax Law. (1982) 13 Pacific L.J. 699.

§ 25300. Short title

This chapter shall be known and may be cited as the Carpenter-Presley-Tanner Hazardous Substance Account Act.

(Added by Stats.1981, c. 756, p. ——, § 2, urgency, eff. Sept. 25, 1981.)

§ 25301. Legislative intent

It is the intent of the Legislature to:

(a) Establish a program to provide for response authority for releases of hazardous substances, including spills and hazardous waste disposal sites that pose a threat to the public health or the environment.

(b) Compensate persons, under certain circumstances, for out-of-pocket medical expenses and lost wages or business income resulting from injuries proximately caused by exposure to release of hazardous substances.

(c) Make available adequate funds in order to permit the State of California to assure payment of its 10 percent share of the costs mandated pursuant to Section 104(c)(3) of the federal act (42 U.S.C. 9604(c)(3)).

(Added by Stats.1981, c. 756, p. ——, § 2, urgency, eff. Sept. 25, 1981.)

Hazardous substance tax, governed by definitions contained in this chapter, see Revenue and Taxation Code § 43002.

§ 25310. Application; definitions in federal act

The definitions set forth in this article shall govern the interpretation of this chapter. Unless the context requires otherwise and except as provided in this article, the definitions contained in Section 101 of the federal act (42 U.S.C. 9601) shall apply to the terms used in this chapter.

(Added by Stats.1981, c. 756, p. ——, § 2, urgency, eff. Sept. 25, 1981.)

§ 25312. Department

"Department" means the State Department of Health Services.

(Added by Stats.1981, c. 756, p. ——, § 2, urgency, eff. Sept. 25, 1981.)

§ 25313. Director

"Director" means the Director of Health Services.

(Added by Stats.1981, c. 756, p. ——, § 2, urgency, eff. Sept. 25, 1981.)

§ 25315. Federal act

"Federal act" means the Comprehensive Environmental Response, Compensation, and Liability Act of 1980, P.L. 96–510 (42 U.S.C. 9601, et seq.).

(Added by Stats.1981, c. 756, p. ——, § 2, urgency, eff. Sept. 25, 1981.)

§ 25316. Hazardous substance; inclusions

"Hazardous substance" means:

(a) Any substance designated pursuant to Section 1321(b)(2)(A) of Title 33 of the United States Code.

(b) Any element, compound, mixture, solution, or substance designated pursuant to Section 102 of the federal act (42 U.S.C. 9602).

(c) Any hazardous waste having the characteristics identified under or listed pursuant to Section 6921 of Title 42 of the United States Code, but not including any waste the regulation of which under the Solid Waste Disposal Act has been suspended by act of Congress.

(d) Any toxic pollutant listed under Section 1317(a) of Title 33 of the United States Code.

(e) Any hazardous air pollutant listed under Section 7412 of Title 42 of the United States Code.

(f) Any imminently hazardous chemical substance or mixture with respect to which the Administrator of the United States Environment Protection Agency has taken action pursuant to Section 2606 of Title 15 of the United States Code.

(g) Any hazardous waste or extremely hazardous waste as defined by Sections 25117 and 25115, respectively, unless expressly excluded.

(Added by Stats.1981, c. 756, p. ——, § 2, urgency, eff. Sept. 25, 1981.)

§ 25317. Hazardous substance; exclusions

"Hazardous substance" does not include:

(a) Petroleum, including crude oil or any fraction thereof which is not otherwise specifically listed or designated as a hazardous substance in subdivisions (a) to (f), inclusive, of Section 25316, and natural gas, natural gas liquids, liquefied natural gas, or synthetic gas usable for fuel (or mixtures of natural gas and such synthetic gas), or the ash produced by a resource recovery facility utilizing a municipal solid waste stream.

(b) Nontoxic, nonflammable, noncorrosive stormwater run-off drained from underground vaults, chambers, or manholes into gutters or stormsewers.

(Added by Stats.1981, c. 756, p. ——, § 2, urgency, eff. Sept. 25, 1981.)

§ 25320. Release; inclusions

"Release" means any spilling, leaking, pumping, pouring, emitting, emptying, discharging, injecting, escaping, leaching, dumping, or disposing into the environment.

(Added by Stats.1981, c. 756, p. ——, § 2, urgency, eff. Sept. 25, 1981.)

§ 25321. Release; exclusions

"Release" does not include any of the following:

(a) Any release which results in exposure to persons solely within a workplace, with respect to a claim such exposed persons may assert against their employer.

(b) Emissions from the engine exhaust of a motor vehicle, rolling stock, aircraft, vessel, or pipeline pumping station engine.

(c) Release of source, byproduct, or special nuclear material from a nuclear incident, as those terms are defined in the Atomic Energy Act of 1954 (42 U.S.C. 2011, et seq.), if such release is subject to requirements with respect to financial protection established by the Nuclear Regulatory Commission under Section 2210 of Title 42 of the United States Code or, for the purposes of Section 104 of the federal act (42 U.S.C. 9604) or any other response action, any release of source byproduct, or special nuclear material from any processing site designated under Section 7912(a)(1) or 7942(a) of Title 42 of the United States Code, which sections are a part of the Uranium Mill Tailings Radiation Control Act of 1978.

(d) The normal application of fertilizer, plant growth regulants, and pesticides.

(Added by Stats.1981, c. 756, p. ——, § 2, urgency, eff. Sept. 25, 1981.)

§ 25322. Remedy or remedial action

"Remedy" or "remedial action" includes those actions which are consistent with a permanent remedy, that are taken instead of, or in addition to, removal actions in the event of a release or threatened release of a hazardous substance into the environment, as further defined by Section 101(24) of the federal act (42 U.S.C. 9601(24)), except that any reference in Section 101(24) of the federal act (42 U.S.C. 9601(24)) to the President, relating to determinations regarding the relocation of residents, businesses, and community facilities shall, for the purposes of this chapter, be deemed to be a reference to the Governor and any other reference in that section to the President shall, for the purposes of this chapter, be deemed a reference to the Governor, or the director, if designated by the Governor.

(Added by Stats.1981, c. 756, p. ——, § 2, urgency, eff. Sept. 25, 1981.)

§ 25323. Remove or removal

"Remove" or "removal" includes the cleanup or removal of released hazardous substances from the environment or the taking of such other actions as may be necessary to prevent, minimize, or mitigate damage which may otherwise result from a release or threatened release, as further defined by Section 101(23) of the federal act (42 U.S.C. 9601(23)).

(Added by Stats.1981, c. 756, p. ——, § 2, urgency, eff. Sept. 25, 1981.)

§ 25324. State account

"State account" means the Hazardous Substance Account established pursuant to Section 25330.

(Added by Stats.1981, c. 756, p. ——, § 2, urgency, eff. Sept. 25, 1981.)

§ 25325. Federally permitted release

"Federally permitted release" shall have the same meaning as that term is defined in Section 101(10) of the federal act (42 U.S.C. 9601(10)).

(Added by Stats.1981, c. 756, p. ——, § 2, urgency, eff. Sept. 25, 1981.)

§ 25326. Release authorized or permitted pursuant to state law

"A release authorized or permitted pursuant to state law" means any release into the environment which is authorized by statute, ordinance, regulation, or rule of any state, regional, or local agency or government or by any specific permit, license, or similar authorization from any such agency, including one of the foregoing which recognizes a standard industry practice, including variances obtained from any such agency which allow operations for facilities during a period of time when releases from such facilities do not conform with relevant statutes, ordinances, regulations, or rules. The terms includes a federally permitted release, as defined by Section 25325, and releases which are in accordance with any court order or consent decree.

(Added by Stats.1981, c. 756, p. ——, § 2, urgency, eff. Sept. 25, 1981.)

ARTICLE 3. HAZARDOUS SUBSTANCE ACCOUNT

Sec.

25330. Establishment; administration; deposits.
25331. Actions in name of account.
25332. Appropriation; loan to account.
25333. Appropriation; loan to account; repayment of principal plus interest.

Article 3 was added by Stats.1981, c. 756, p. ——, § 2, urgency, eff. Sept. 25, 1981.

§ 25330. Establishment; administration; deposits

There is in the General Fund a Hazardous Substance Account which shall be administered by the director. In addition to any other moneys appropriated by the Legislature to the account, the following amounts shall be deposited in the account:

(a) All moneys recovered by the state account pursuant to Section 25360.

(b) Any moneys recovered by the State Board of Control pursuant to Section 25380.

(c) Any fines or civil penalties collected pursuant to Section 25343.

(d) The taxes collected pursuant to Article 4 (commencing with Section 25340).

(e) Any interest earned upon money deposited in the state account.

(f) Any moneys received from the federal government pursuant to the federal act.

(Added by Stats.1981, c. 756, p. ——, § 2, urgency, eff. Sept. 25, 1981.)

Collections pursuant to this article to be deposited in hazardous substance account, see § 25330.

§ 25340. Board

"Board," as used in this article, means the State Board of Equalization.

(Added by Stats.1981, c. 756, p. ——, § 2, urgency, eff. Sept. 25, 1981.)

§ 25341. Dispose or disposal

(a) "Dispose" or "disposal," as used in this article, means to abandon, deposit, inter, or otherwise discard waste into or on land as a final action after use has been achieved and no intended beneficial use or reuse can be demonstrated by any person.

(b) "Dispose" or "disposal" shall not include any injection of fluids or other materials for the purpose of stimulating or treating wells for the production of crude oil, natural gas, water or geothermal energy or for the purpose of secondary, tertiary, or other enhanced recovery of crude oil or natural gas, or fluids or other materials which are brought to the surface in conjunction with the production of geothermal resources, crude oil or natural gas and which are reinjected.

(Added by Stats.1981, c. 756, p. ——, § 2, urgency, eff. Sept. 25, 1981.)

§ 25342. Annual disposal report; submission; contents

On or before March 1, 1982, and March 1 of each year thereafter, every person who submitted for disposal offsite, or who disposed of onsite, hazardous waste or extremely hazardous waste in the state during the preceding calendar year shall report to the board the following information:

(a) The total amount of hazardous or extremely hazardous waste, as defined by Sections 25117 and 25115, respectively, the federal regulation of which has been suspended under the Solid Waste Disposal Act (42 U.S.C. 6901) by act of Congress, which that person has disposed of, or submitted for disposal, in the state, plus the total amount of hazardous or extremely hazardous waste and material,

* * * which that person has transferred to a surface impoundment in the state for purposes of reducing the water content of the waste and material by evaporation, exclusive of that waste specified in subdivision (d).

(b) The total amount of hazardous waste disposed of, or submitted for disposal, in the state by that person, exclusive of that waste specified in subdivisions (a), (c), and (d).

(c) The total amount of extremely hazardous waste disposed of, or submitted for disposal, in the state by that person, exclusive of that waste specified in subdivisions (a), (b), and (d).

(d) The total amount of hazardous or extremely hazardous waste that person has disposed of, or submitted for disposal, in the state from the extraction, beneficiation, and processing of ores and minerals, including phosphate rock and overburden from mining of uranium ore.

§ 25345. Imposition of tax; formula; assessment notice; payment; subsequent removal of waste to another place; exception

(a) There is hereby imposed a tax, payable annually, and to be collected by the board, upon each ton or fraction thereof, of waste and material specified in Section 25342, according to the formula specified herein. The board shall set the base tax rate upon the waste and material specified in Section 25342 in accordance with the following formula:

$$\text{Base tax rate} = \frac{(\$10{,}000{,}000 - M)}{(0.15W_1 + W_2 + 2W_3 + 0.01W_4)}$$

where:

(1) "M" is the existing unobligated balance in the fund * * * (M shall equal zero (0) for * * * June 30, 1982). As used in this article, "unobligated balance" means all unencumbered funds in the account as of June 30, as estimated on March 1 of each year, less:

(A) Any funds in the reserve account for emergencies established by Section 25354.

(B) Any remaining principal of the loan authorized by Section 25332.

(C) Any interest due on any remaining principal of the loan authorized by Section 25332.

(D) Any funds paid as taxes for the following fiscal year.

(E) Any funds received from the federal government pursuant to the federal act.

The unobligated balance shall not be less than zero (0).

(F) Any funds in the state account subject to the rebate specified in Section 25347.2.

(2) W_1 is the total amount in tons of waste and material specified in subdivision (a) of Section 25344.

(3) W_2 is the total amount in tons of waste specified in subdivision (b) of Section 25344.

(4) W_3 is the total amount in tons of waste specified in subdivision (c) of Section 25344.

(5) W_4 is the total amount in tons of waste specified in subdivision (d) of Section 25344.

(b) On or before May 1 of each year, using the formula specified in subdivision (a), the board shall determine the base tax rate for the current year.

(c) The tax imposed upon each person subject to Section 25342 shall be assessed according to the following formula:

$$\text{Tax} = (\text{base tax rate}) \times (0.15\,P_1 + P_2 + 2P_3 + 0.01P_4)$$

where:

(1) "Base tax rate" equals the figure determined pursuant to subdivision (a).

(2) P_1 is the amount in tons of waste and material specified by the person pursuant to subdivision (a) of Section 25342.

(3) P_2 is the amount in tons of waste specified by the person pursuant to subdivision (b) of Section 25342.

(4) P_3 is the total amount in tons of waste specified by the person pursuant to subdivision (c) of Section 25342.

(5) P_4 is the total amount in tons of waste specified by the person pursuant to subdivision (d) of Section 25342.

(d) On or before May 1 of each year, the board shall send to each person subject to Section 25342 a notice of assessment * * *.

(e) On or before July 1 of each year, each person subject to Section 25342 shall pay to the board the amount of the assessment as stated in the notice. The tax under this chapter shall not be imposed again on hazardous waste or extremely hazardous waste if the waste, or any portion thereof, is removed subsequently to another place for disposal * * * and if the person has paid the amount of assessment for the waste in accordance with this section before the removal thereof.

(f) Notwithstanding any other provision of this section, hazardous wastes disposed of into an injection well during the 1981 calendar year shall be subject to a tax rate that does not exceed 26.4 percent of the base tax rate, as determined in subdivision (a), per ton or fraction thereof. For purposes of this section, the following definitions apply:

(1) "Injection well" means a bored, drilled or driven shaft, whose depth is greater than the largest surface dimension, and which is used to inject hazardous waste into an underground formation. Injection well does not mean any well located in Class I or a Class II-1 disposal site, as defined in Sections 2510 and 2511 of Title 23 of the California Administrative Code, on the effective date of this section.

(2) "Formation" means a body of rock characterized by a degree of lithologic homogenity which is prevailingly, but not necessarily, tabular and is mapable on the earth's surface or traceable in the subsurface.

(Added by Stats.1981, c. 756, p. ——, § 2, urgency, eff. Sept. 25, 1981. Amended by Stats.1982, c. 327, p. ——, § 118, urgency, eff. June 30, 1982; Stats.1982, c. 496, p. ——, § 15, urgency, eff. § 25345.3. State or local agencies; removal or release of hazardous waste

(a) Any state or local agency, or its contractor, which removes or remedies a release, by another person, of hazardous waste or extremely hazardous waste, shall not be subject to the requirements of Sections 25342 and 25345. This subdivision shall be applicable to all acts performed by a state or local agency, or its contractor, on or after September 25, 1981.

(b) The person responsible for a release of hazardous or extremely hazardous waste, which has been removed or remedied by a state or local agency, or its contractor, shall submit to the board the information required by Section 25342 for the hazardous or extremely hazardous waste which was released and shall also pay the tax provided in Section 25345.

(Added by Stats.1982, c. 496, p. ——, § 16, urgency, eff. July 12, 1982.)

§ 25345.5. Exemptions from recordkeeping requirements and tax; voluntary hazardous waste collection program, definition; regulation of hazardous waste collections

Neither the recordkeeping requirements of Section 25342 nor the tax provided in Section 25345 shall apply to local health officers or county agricultural commissioners if the local health officers or county agricultural commissioners are conducting voluntary hazardous waste collection programs and if the total quantities collected are limited to 1,000 kg. or less per month from all sources; provided, however, that they comply with all requirements of Chapter 6.5 (commencing with Section 25100) and regulations adopted pursuant thereto. For the purposes of this section, "voluntary hazardous waste collection program" means a program in which small quantities of hazardous wastes are received from nonindustrial sources, stored, and ultimately transferred to a licensed hazardous waste disposal site. Any hazardous waste collections in excess of 1,000 kg. per month shall be subject to all requirements of this chapter and Chapter 6.5 (commencing with Section 25100) and regulations adopted pursuant thereto, including, but not limited to, those providing for payment of taxes and recordkeeping.

§ 25347.2. State account rebate; computation; credit or payment; appropriation

(a) "State account rebate" means the total taxes, interest and penalties for any preceding calendar year which have been collected during the previous 12-month period, pursuant to Section 25345 and Part 22 (commencing with Section 43001) of Division 2 of the Revenue and Taxation Code, less the total of:

(1) Ten million dollars ($10,000,000), or the amount appropriated for the current fiscal year by the Legislature for the purposes of this chapter, whichever is the lesser amount.

(2) The total amount of refunds of tax, interest and penalties paid during the previous 12-month period.

(3) The total amount of claims for refund filed and pending, to the extent that these claims relate to tax, interest and penalties collected during the previous 12-month period.

(b) "Previous 12-month period" means the period from March 1 of the preceding year to March 1 of the current year.

(c) On or before June 1 of each year the State Board of Equalization shall compute the amount of the state account rebate for the previous 12-month period. The state account rebate shall be credited or paid to each person who paid taxes for the preceding calendar year pursuant to Section 25345 and Part 22 (commencing with Section 43001) of Division 2 of the Revenue and Taxation Code on a pro rata basis in proportion to the amount of taxes, interest and penalties paid by that person for the preceding year.

(d) The amount of any credit or payment for the state account rebate shall be accompanied by a brief explanation or statement of account and may be reflected in the notice of assessment for the current year.

(e) There is hereby continuously appropriated from the Hazardous Substance Account in the General Fund, to the State Board of Equalization, sufficient funds to pay the state account rebates authorized by this section.

ARTICLE 5. USES OF THE STATE ACCOUNT

Sec.

25350. Response actions qualifying for appropriation and expenditure; duplication of federal response action prohibited.
25351. Administrative costs and expenses; state share mandated by federal act; equipment; removal costs; studies; use of federal funds; rules and regulations.
25352. Appropriation on specific site basis; restoration of natural resources; assessment of long-term and short-term injury; unavoidable injury excluded; recovery of expenditures.
25353. Remedial action where governmental entity liable for costs; occurrences prior to effective date of this chapter.
25354. Reserve account for emergencies; continuous appropriation; uses; contracts; reports; maximum deposit and appropriation; reversion and deposit of unencumbered balance.
25355. Sites requiring remedial action; coordination of state response actions; responsible party; when director to initiate removal or remedial action.
25356. Sites for remedial action; criteria for selection and priority ranking; publication and revision; expenditure of funds [New].
25356.5. Report to Legislative; sites upon which funds are proposed to be expended; expenditure of funds [New].
25357. Expenditures exceeding amount in state account.
25358. Federal funds; cooperative agreements.

Article 5 was added by Stats.1981, c. 756, p. ——, § 2, urgency, eff. Sept. 25, 1981.

§ 25350. Response actions qualifying for appropriation and expenditure; duplication of federal response action prohibited

For response actions taken pursuant to the federal act, only those costs for actions which are consistent with the priorities, guidelines, criteria, and regulations contained in the national contingency plan, as revised and republished pursuant to Section 105 of the federal act (42 U.S.C. 9605), shall qualify for appropriation by the Legislature and expenditure by the director pursuant to Sections 25351, 25352, and 25354. For response actions not taken pursuant to the federal act or for response actions taken which are not specifically addressed by the priorities, guidelines, criteria, and regulations contained in the national contingency plan, as revised and republished, the costs thereof shall also qualify for appropriation by the Legislature and expenditure by the department pursuant to Sections 25351, 25352, and 25354 provided they are, to the maximum extent possible, consistent with the priorities, guidelines, criteria, and regulations contained in the national contingency plan for similar releases, situations, or events. No response actions taken pursuant to this chapter by the department or regional or local agencies shall duplicate federal response actions.

(Added by Stats.1981, c. 756, p. ——, § 2, urgency, eff. Sept. 25, 1981.)

§ 25351. Administrative costs and expenses; state share mandated by federal act; equipment; removal costs; studies; use of federal funds; rules and regulations

Consistent with the requirements of Section 114(c) of the federal act (42 U.S.C. 9614(c)), moneys in the state account may be expended by the director, upon appropriation by the Legislature, for the following purposes:

(a) The costs and expenses reasonably necessary for, and incidental to, the administration of this apter by the department.

(b) The state share mandated pursuant to Section 104(c)(3) of the federal act (42 U.S.C. 9604(c)(3)).

(c) The purchase by the state, or by any local agency with the prior approval of the director, of zardous substance response equipment and other preparations for response to a release of hazardous bstances. However, all equipment shall be purchased in a cost-effective manner after consideration the adequacy of existing equipment owned by the state or the local agency, and the availability of uipment owned by private contractors.

(d) For reimbursement of all costs of removal and remedial action incurred by the state, or by any al agency with the approval of the director, in response to a release or threatened release of a zardous substance to the extent the costs are not reimbursed by the federal act.

(e) All costs incurred in cooperation with the Agency for Toxic Substances and Disease Registry tablished pursuant to Section 104(i) of the federal act (42 U.S.C. 9604(i)) and all costs of health fects studies undertaken regarding specific sites or specific substances at specific sites. Funds propriated for this purpose shall not exceed five hundred thousand dollars ($500,000) in any single cal year. However, such actions shall not duplicate reasonably available federal actions and studies.

(f) All federal funds deposited in the state account shall be expended for the purposes for which ey were provided to the state.

(g) The department shall adopt any regulations necessary to carry out its responsibilities pursuant this chapter, including, but not limited to, regulations governing the expenditure of, and accounting ocedures for, moneys allocated to state, regional, and local agencies pursuant to this chapter.

dded by Stats.1981, c. 756, p. ——, § 2, urgency, eff. Sept. 25, 1981.)

25352. Appropriation on specific site basis; restoration of natural resources; assessment of long-term and short-term injury; unavoidable injury excluded; recovery of expenditures

Money deposited in the state account may also be appropriated by the Legislature to the partment on a specific site basis for the following purposes:

(a) For all costs incurred in restoring, rehabilitating, replacing, or acquiring the equivalent of, any atural resource injured, degraded, destroyed, or lost as a result of any release of a hazardous bstance, to the extent the costs are not reimbursed pursuant to the federal act and taking into count processes of natural rehabilitation, restoration, and replacement.

(b) For all costs incurred in assessing short-term and long-term injury to, degradation or destruction of, or any loss of any natural resource resulting from a release of a hazardous substance, to the tent that the costs are not reimbursed pursuant to the federal act. No costs may be incurred for ay release of a hazardous substance from any facility or project pursuant to subdivisions (a) or (b) for jury, degradation, destruction, or loss of any natural resource where such injury, degradation, struction, or loss was specifically identified as an irreversible and irretrievable commitment of atural resources in an environmental impact statement prepared under the authority of the National vironmental Policy Act (42 U.S.C. 4341, et seq.), or was identified as a significant environmental ffect to such natural resources which cannot be avoided in an environmental impact report prepared ursuant to the provisions of the California Environmental Quality Act, Division 13 (commencing with ection 21000) of the Public Resources Code, and a decision to grant a permit, license, or similar uthorization for any facility or project is based upon a consideration of such significant environmental effects to such natural resources, and the facility or project was otherwise operating within the erms of its permit, license, or similar authorization at the time of release.

(c) Notwithstanding the provisions of Section 25355, the Governor, or the authorized representative f the state, shall act on behalf of the public as trustee of such natural resources to recover costs xpended pursuant to subdivision (a) or (b).

§ 25353. Remedial action where governmental entity liable for costs; occurrences prior to effective date of this chapter

(a) No money shall be available for remedial action with respect to facilities, owned or operated by a government entity at the time of disposal to the extent that the governmental entity would otherwise be liable for such costs.

(b) No money may be used for the purposes specified in Section 25352 where the injury, degradation, destruction, or loss to natural resources, or the release of a hazardous substance from which such damages to natural resources resulted, has occurred prior to the effective date of this chapter.

(Added by Stats.1981, c. 756, p. ——, § 2, urgency, eff. Sept. 25, 1981.)

§ 25354. Reserve account for emergencies; continuous appropriation; uses; contracts; reports; maximum deposit and appropriation; reversion and deposit of unencumbered balance

(a) There is hereby continuously appropriated from the state account to the department * * *, the sum of one million dollars ($1,000,000) for each fiscal year as a reserve account for emergencies. The department may expend moneys available in the reserve account for the purpose of taking immediate corrective action necessary to remedy or prevent an imminent substantial danger to the public health or the environment caused by the release or threatened release of a hazardous substance.

(b) Notwithstanding any other provision of law, the department may enter into written contracts for corrective action taken or to be taken pursuant to subdivision (a), and may enter into oral contracts, not to exceed two thousand dollars ($2,000) in obligation, when in the judgment of the department immediate corrective action is necessary to remedy or prevent an imminent substantial danger to the public health, domestic livestock, wildlife, or the environment. Such contracts, whether written or oral, may include provisions for the rental of tools or equipment, either with or without operators furnished, and for the furnishing of labor and materials necessary to accomplish the work. Any such contract by the department shall be exempt from approval by the Department of General Services pursuant to the provisions of Section 14780 of the Government Code.

(c) Any disbursement made pursuant to subdivision (a) shall be reported to the Director of Finance within 72 hours of commencement of the corrective action taken.

(d) Once the appropriation made pursuant to subdivision (a) is fully expended, the director shall file a report with the Legislature if it is in session, or if it is not in session, with the Committee on Rules of the Assembly and the Senate as to the moneys expended pursuant to this section. The Legislature may appropriate moneys from the state account, in addition to those appropriated pursuant to subdivision (a), to the department for the purpose of taking corrective action pursuant to subdivision (a).

(e) Except as provided in subdivision (d), in no event shall the amount deposited in the reserve account and appropriated pursuant to this section exceed one million dollars ($1,000,000) in any fiscal year. On June 30 of each year the unencumbered balance of the reserve shall revert to and be deposited in the state account.

(Added by Stats.1981, c. 756, p. ——, § 2, urgency, eff. Sept. 25, 1981. Amended by Stats.1982, c. 327, p. ——, § 120, urgency, eff. June 30, 1982.)

§ 25356. Sites for remedial action; criteria for selection and priority ranking; publication and revision; expenditure of funds

(a) Except as provided in Section 25356.5, on or before April 1, 1983, the department shall adopt by regulation the criteria for the selection and for the priority ranking of sites for remedial action under this chapter. The criteria shall take into account the pertinent factors relating to the public health and the environment, which shall include, but are not limited to, potential hazards to public health and environment, the risk of fire or explosion, toxic hazards, and the criteria established pursuant to Section 105(8) of the federal act (42 U.S.C. 9605(8)).[1]

(b) The department shall publish and revise at least annually a priority ranking of sites. The list shall be transmitted to the Legislature on or before January 10 of each year. The development and publication of the priority ranking of sites shall be subject to the regulations adopted under subdivision (a).

(c) The department's development and publication of the priority ranking of sites shall not be subject to the provisions of Chapter 3.5 (commencing with Section 11340) of Part 1 of Division 3 of Title 2 of the Government Code.

(d) Funds appropriated to the department for remedial action shall be expended in conformance with the priority ranking of sites. Funds may be expended on more than one site on the list at any one time.

(Added by Stats.1982, c. 327, p. ——, § 122, urgency, eff. June 30, 1982; Stats.1982, c. 496, p. ——, § 16.7, urgency, eff. July 12, 1982.)

[1] 42 U.S.C.A. § 9605(8).

1982 Legislation.

The addition by Stats.1982, c. 327, § 122 read as follows:

"(a) On or before April 1, 1983, the department shall adopt by regulation the criteria for the selection and for the priority ranking of sites for remedial action under this chapter. The criteria shall take into account pertinent factors relating to the public health and the environment. These factors shall include, but are not limited to, potential hazards to public health and environment, the risk of fire or explosion, toxic hazards, and the criteria established pursuant to Section 105(8) of the federal act (42 U.S.C. 9605(8)).

"(b) The department shall publish and revise at least annually a priority ranking of sites. The list shall be transmitted to the Legislature on or before January 10 of each year. The development and publication of the priority ranking of sites shall be subject to the regulations required by subdivision (a) when they are adopted, but shall not be subject to the provisions of Chapter 3.5 (commencing with Section 11340) of Part 1 of Division 3 of Title 2 of the Government Code.

"(c) Funds appropriated to the department for remedial action shall be expended in conformance with the priority ranking of sites. Funds may be expended on more than one site on the list at any one time."

Former § 25356, added by Stats.1981, c. 756, p. ——, § 2, relating to similar subject matter, was repealed by Stats.1982, c. 327, p. ——, § 121, urgency, eff. June 30, 1982; Stats.1982, c. 496, p. ——, § 16.3, urgency, eff. July 12, 1982.

Derivation: Former § 25356, added by Stats.1981, c. 756, p. ——, § 2.

§ 25356.5. Report to Legislature; sites upon which funds are proposed to be expended; expenditure of funds

On or before July 1, 1982, the department shall provide a report to the Legislature which lists the sites upon which funds are proposed to be expended during the 1982–83 fiscal year and the criteria and rationale upon which the list is based. Funds appropriated to the department from the account for remedial action for fiscal year 1982–83 shall be expended by the department only on those sites listed in this report.

(Added by Stats.1982, c. 327, p. ——, § 123, urgency, eff. June 30, 1982; Stats.1982, c. 496, p. ——, § 16.9, urgency, eff. July 12, 1982.)

1982 Legislation.

The addition of this section by Stats.1982, c. 327, § 123 and c. 496, § 16.9, was identical, except the beginning of the first sentence in c. 327, § 123, read: "Notwithstanding the provisions of Section 25356 on or before July 1, 1982, * * *".

§ 25357. Expenditures exceeding amount in state account

Expenditures from the state account shall not be made in excess of the total amount of money in the state account at any one time. Expenditures in excess of such amount may be made only when additional money is collected or otherwise added to the state account.

(Added by Stats.1981, c. 756, p. ——, § 2, urgency, eff. Sept. 25, 1981.)

§ 25358. Federal funds; cooperative agreements

The state shall actively seek to obtain all federal funds to which it is entitled under the federal act and shall take all actions necessary to enter into contractual or cooperative agreements under Sections 104(c)(3) and 104(d)(1) of the federal act (42 U.S.C. 9604(c)(3) and 42 U.S.C. 9604(d)(1)).

§ 25373. Claims; forms and procedures; minimum requirements; giving false information; pena ty

The board shall prescribe appropriate forms and procedures for claims filed pursuant to this artic which shall include, as a minimum, all of the following:

(a) A provision requiring the claimant to make a sworn verification of the claim to the best of his her knowledge.

(b) A full description, supported by appropriate evidence from government agencies of the rele of the hazardous substance claimed to be the cause of the physical injury or illness or loss of incor

(c) Certification by the claimant of dates and places of residence for the five years preceding date of the claim.

(d) Certification of the medical history of the claimant for the five years preceding the date of claim, along with certification of the alleged physical injury or illness and expenses for such physi injury or illness. Such certification shall be made by hospitals, physicians, or other qualified med authorities.

(e) The claimant's income as reported on the claimant's federal income tax return for the preceding three years in order to compute lost wages or income.

(f) Any person who knowingly gives, or causes to be given, any false information as a part of any such claim shall be guilty of a misdemeanor and shall, upon conviction, be fined up to five thousand dollars ($5,000), or imprisoned for not more than one year, or both.

(Added by Stats.1981, c. 756, p. ——, § 2, urgency, eff. Sept. 25, 1981.)

Cross References

Authority to revise rules and regulations to determine that claimant has exercised reasonable diligence under this section, see § 25381.

§ 25374. Decisions; time; final agency action for purposes of judicial review

All decisions rendered by the board shall be in writing, with notification to all appropriate parties, and shall be rendered within 90 days of submission of a claim to the board unless all the parties to the claim agree in writing to an extension of time. Such decision shall be considered a final agency action for the purposes of judicial review of such decision by any party to the proceedings resulting in such decision.

(Added by Stats.1981, c. 756, p. ——, § 2, urgency, eff. Sept. 25, 1981.)

§ 25375. Compensable losses; exclusion

The following losses shall be compensable pursuant to this article, provided that the board has found that the claimant has established, by the weight of the evidence, that such losses were proximately caused by the designated release:

(a) One hundred percent of uninsured, out-of-pocket medical expenses, for up to three years from the onset of treatment.

(b) Eighty percent of any uninsured, actual lost wages, or business income in lieu of wages, caused by injury to the claimant or the claimant's property, not to exceed fifteen thousand dollars ($15,000) per year for three years.

No money shall be used for the payment of any claim authorized by this chapter, where such claim is the result of long-term exposure to ambient concentrations of air pollutants.

(Added by Stats.1981, c. 756, p. ——, § 2, urgency, eff. Sept. 25, 1981.)

§ 25376. Limitations

No claim may be presented to the board pursuant to this article later than three years from the date of discovery of the loss or from January 1, 1982, whichever is later.

(Added by Stats.1981, c. 756, p. ——, § 2, urgency, eff. Sept. 25, 1981.)

§ 25377. Claim against board not condition precedent to other remedy

Nothing in this article shall require, or be deemed to require, pursuit of any claim against the board as a condition precedent to any other remedy.

(Added by Stats.1981, c. 756, p. ——, § 2, urgency, eff. Sept. 25, 1981.)

§ 25378. Compensation pursuant to this article to preclude indemnification or reimbursement from other sources and vice versa

Compensation of any loss pursuant to this article shall preclude indemnification or reimbursement from any other source for the identical loss, and indemnification or reimbursement from any other source shall preclude compensation pursuant to this article.

(Added by Stats.1981, c. 756, p. ——, § 2, urgency, eff. Sept. 25, 1981.)

§ 25379. Compensation, decision, or settlement; admissibility as evidence

No compensation or decision under this chapter shall be admissible as evidence of any issue of fact or law in any proceeding brought under any other section of this division or under any other provision of law, including common law. In addition, no settlement reached pursuant to this chapter shall be admissible as evidence in any such proceeding.

(Added by Stats.1981, c. 756, p. ——, § 2, urgency, eff. Sept. 25, 1981.)

Underline indicates changes or additions by amendment

§ 25380. Subrogation by state

Compensation of any loss pursuant to this article shall be subject to the state's acquiring, by subrogation, all rights of the claimant to recover such loss from the party determined to be liable therefor. Upon the request of the board, the Attorney General shall commence an action to recover any amount paid in compensation for any loss pursuant to this article against any party who is liable to the claimant for any loss compensable pursuant to this article in accordance with the procedures set forth in Sections 25360 to 25364, inclusive. Moneys recovered pursuant to this section shall be deposited in the state account.

(Added by Stats.1981, c. 756, p. ——, § 2, urgency, eff. Sept. 25, 1981.)

Cross References
Recoveries pursuant to this section to be deposited in hazardous substance account, see § 25330.

§ 25381. Rules and regulations; payment of claims; appropriations

The board shall adopt, and revise when appropriate, all rules and regulations necessary to implement the provisions of this article, including methods that provide for establishing that a claimant has exercised reasonable diligence in satisfying the conditions specified in Sections 25372 and 25373 and regulations that specify the proof necessary to establish a loss compensable pursuant to this article.

(a) Claims approved by the board under the provisions of this article shall be paid from the Hazardous Substance Compensation Account.

(b) The Legislature may, commencing July 1, 1982, appropriate up to two million dollars ($2,000,000) annually from the state account to the Hazardous Substance Compensation Account to be used as a revolving fund by the board for the payment of awards pursuant to this article. However, the total amount in the Hazardous Substance Compensation Account shall not exceed two million dollars ($2,000,000) in any fiscal year.

(c) Claims against or presented to the board shall not be paid in excess of the amount of money available in the Hazardous Substance Compensation Account. Such claims shall be paid only when additional money is collected, appropriated, or otherwise added to that account.

§ 25395. Duration of chapter; duration of hazardous substance tax

This chapter and the tax imposed by Section 25345 shall remain in effect only until July 1, 1991, an as of such date is repealed, unless a later enacted statute, which is chaptered before July 1, 1991 deletes or extends such date.

(Added by Stats.1981, c. 756, p. ——, § 2, urgency, eff. Sept. 25, 1981.)

A BILL

TO AMEND CHAPTER 56 OF TITLE 44, CODE OF LAWS OF SOUTH CAROLINA, 1976, AS AMENDED, RELATING TO HAZARDOUS WASTE MANAGEMENT, SO AS TO DELETE THE EXCLUSION FOR SOURCE, SPECIAL NUCLEAR, OR BY-PRODUCT MATERIAL AS DEFINED BY THE ATOMIC ENERGY ACT OF 1954 AND TO AMEND THE USE OF THE HAZARDOUS WASTE CONTINGENCY FUND TO INCLUDE REMEDY FOR PROBLEMS AT UNCONTROLLED HAZARDOUS WASTE SITES.

Be it enacted by the General Assembly of South Carolina:

SECTION 1: Subsection (6) of Section 44-56-20 of the 1976 Code is amended to read as follows:

"(6) "Hazardous waste" means any waste, or combination of wastes, of a solid, liquid, contained gaseous, or semisolid form which because of its quantity, concentration, or physical, chemical, or infectious characteristics may in the judgment of the Department:

a. cause, or significantly contribute to an increase in mortality or an increase in serious irreversible, or incapacitating reversible illness; or

b. pose a substantial present or potential hazard to human health or the environment when improperly treated, stored, transported, or disposed of, or otherwise managed. Such wastes may include, but are not limited to, those which are toxic, corrosive, flammable, irritants, strong sensitizers, persistent in nature, assimilated or concentrated in tissue, or which generate pressure through decomposition, heat or other means. The term does not include solid or dissolved materials in domestic sewage, or solid dissolved materials in irrigation return flows, or industrial discharges which are point sources subject to NPDES permits under the Federal Water Pollution Control Act or the Pollution Control Act of South Carolina or materials covered under Article 2 of Chapter 7 of Title 13 of the 1976 Code as amended."

SECTION 2: Section 44-56-20 of the 1976 Code is amended by adding the following new subsection:

"(13) "Uncontrolled hazardous waste site" means any site where hazardous wastes or other hazardous substances have been released, abandoned, or otherwise improperly managed so that governmental response action is deemed necessary to remedy actual or potential damages to public health or welfare or the environment.

For the purposes of this item the term Hazardous Waste does not include petroleum, including crude oil or fraction thereof; natural gas; natural gas liquids; liquified natural gas; synthetic gas usable for fuel; or mixtures of natural gas and such synthetic gas."

SECTION 3: Section 44-56-60 of the 1976 Code is amended to read as follows:

"Section 44-56-60. Requirements for treatment, storage and disposal facilities.

A. No person shall construct, substantially alter, or operate any hazardous waste treatment, storage or disposal facility or site, nor shall any person store, treat or dispose of any hazardous waste without first obtaining a permit from the department for such facility, site or activity.

B. Any person who:

1. Owns or operates a facility required to have a permit under this section which facility is in existence on the effective date of this chapter; and

2. Has complied with the requirements of Section 44-56-120; and

3. Has made an application for a permit under this section;

shall be deemed to have been issued such permit until such time as final administrative disposition of each application is made by the department, unless final administrative disposition of each application has not been made because of the failure of the applicant to furnish information reasonably required or requested in order to process the application.

C. Before issuance of a permit, the Department shall require:

1. Evidence of liability insurance for sudden and nonsudden accidental occurrences in such amount as the Department may determine necessary for the protection of the public health and safety of the environment; and.

2. Evidence of financial assurance in such form and amount as the Department may determine to be necessary to ensure that, upon abandonment, cessation or interruption of the operation of a facility or site, all appropriate measures are taken to prevent present and future damages to the public health and safety and to the environment.

D. No person who owns or operates a treatment, storage or disposal facility shall accept a hazardous waste which is generated in another state and is banned or prohibited in any manner by any statute, regulation or administrative decision of that state. Written documentation demonstrating compliance with this requirement shall be submitted to the Department for all hazardous wastes imported into this state prior to their transport.

SECTION 4: Section 44-56-90 of the 1976 Code is amended to read as follows:

"Section 44-56-90. Right of Entry.

A. For the purpose of enforcing this chapter or any regulations authorized pursuant thereto, any authorized representative or employee of the department may, upon presentation of appropriate credentials, at any reasonable time:

1. Enter any place where hazardous wastes are generated, stored, treated or disposed of;

2. Inspect and copy any records, reports, information, or test results relating to the purpose of this chapter; and

3. Inspect and obtain samples from any person of any wastes including samples from any vehicles in which wastes are being transported, as well as samples of any containers or labels. The Department shall provide a sample of equal volume or weight to the owner, operator or agent in charge upon request. The Department shall also provide the owner, operator, or agent in charge a copy of the results of any analyses of such samples.

B. For the purpose of implementing necessary governmental response actions as provided in Section 44-56-180, the Department or its authorized representative may, at any time, enter the premises of any publicly or privately owned property which it has determined to be an uncontrolled hazardous waste site. The owner or operator of such site shall cooperate fully with the department when such governmental response actions are taken."

SECTION 5: Section 44-56-160 of the 1976 Code, as amended by Act No. 517 Part II of 1980, is further amended to read as follows:

"Section 44-56-160. Hazardous Waste Contingency Fund.

The Department of Health and Environmental Control is hereby authorized and directed to establish a Hazardous Waste Contingency Fund to ensure the availability of funds for contingencies arising from permitted hazardous waste landfills and to defray the costs of governmental response actions at uncontrolled hazardous waste sites. The Contingency Fund shall be financed through the imposition of fees provided in Section

44-56-170 and such annual appropriations as may be provided by the General Assembly. Provided, that an amount equal to $1.50 per ton for wastes reported under Section 44-56-170(A) and $2.00 per ton for wastes reported under Section 44-56-170(C) shall be held separate and distinct with the Fund for the purpose of mitigating any contingencies arising from the operation of permitted land disposal facilities in this State. Any interest accruing from the management of the funds held pursuant to this section shall be credited to the Contingency Fund."

SECTION 6: Section 44-56-170 of the 1976 Code, as amended by Act No. 517 Part II of 1980, is further amended to read as follows:

"Section 44-56-170. Reporting requirements and payment of fees into the Hazardous Waste Contingency Fund:

A. There is hereby imposed a fee of $5.00 per ton of hazardous wastes which are generated and disposed of in this state by landfilling or other means of land disposal.

B. Each generator shall, no later than thirty (30) days after the end of each calendar quarter, submit a report to the Department containing the following information:

1. the types and quantities of hazardous wastes generated;

2. the types and quantities of such wastes stored, treated and disposed of by landfilling or other means of land disposal; and

3. a check made payable to the department for the amount of fee imposed on such wastes by the provisions of paragraph A and D.

C. Each owner/operator of a hazardous waste land disposal facility shall submit a similar report to the one described in B above for all hazardous wastes generated outside of the State and received at the facility during the quarter except that the fee imposed shall be the same as that fee charged on out of state waste in the state from which the hazardous waste originated but no less than $7.50 per ton."

D. Each owner or operator of a facility permitted under the provision of Section 44-56-60 shall no later than 30 days of the end of each calendar quarter, submit a report containing types and quantities of wastes stored and a check made payable to the Department in an amount equal to $1.00 per ton for each ton of hazardous wastes stored at the end of the reporting period.

SECTION 7: Section 44-56-180 of the 1976 Code, as amended by Act No. 517 Part II of 1980, is further amended to read as follows:

"Section 44-56-180. Administration of Hazardous Waste Contingency Fund.

A. In determining the use of the fund for a particular governmental response action, the Department shall consider the relative risk of danger to public health or welfare or the environment and the hazard potential of the substances involved including potential for fire, explosions, release of harmful air contaminants, direct human contact, contamination of surface water or groundwater including those used for drinking water supplies, and damages to sensitive ecosystems. In taking a Governmental response action and coincident to the use of the fund, the Department shall initiate the appropriate administrative action to exhaust any applicable liability insurance or other financial assurance mechanisms which have been provided by the responsible party as required pursuant to Section 44-56-60 including where appropriate funds available through P.L.96-510. The Department shall annually make a report to the General Assembly on the activities and response actions tha have been carried out under the auspices of the Contingency Fund..

B. When the amount of monies collected and paid into the fund reaches in the aggregate 7.5 million dollars, the Department shall provide a report to the presiding officers of both Houses of the General Assembly outlining the accomplishments of cleanup activities at uncontrolled hazardous waste sites and the need to continue or discontinue the collection of fees for such purposes. The General Assembly shall, within ninety (90) days of receipt of the report by both presiding officers, evaluate the report and take action to continue the collection of fees or take whatever action deemed necessary for this purpose. Provided, however, that if the specified amount is collected and the General Assembly is not in session the collection of fees shall continue until the report is presented at the next convening session.

SECTION 8: Section 44-56-190 of the 1976 Code, as amended by Act No. 517 Part II of 1980, is further amended to read as follows:

"Section 44-56-190. Hazardous Waste Contingency Fund; Inconsistent regulations to be revised.

The Department is directed to revise and amend the necessary provisions of R.61-79 (DHEC) which are contrary or inconsistent with the provisions of this Act."

Robert M. Adams
Senior Vice President

3M

Rep. Elliott Levitas
Chairman, Subcommittee on
Investigations and Oversight
Public Works and Transportation Committee
B-376 Rayburn Building
Washington, D.C. 20515

Dear Rep. Levitas:

This is a response to your invitation to comment as part of the November 8 and 9, 1983, hearing of the Investigations and Oversight Subcommittee concerning review of the Comprehensive Environmental Response, Compensation, and Liability Act of 1980. We appreciate your courtesy in keeping the hearing record open and welcome the opportunity to present 3M comments on victim compensation to the Subcommittee.

In recent years, 3M has played an active role in the development of environmental policy in Minnesota, particularly in waste management; and our technical experts have been invited to participate in numerous state and federal government sponsored waste management programs. At these programs, there always seems to be considerable interest in the 3M Pollution Prevention Pays program which has been widely recognized throughout the world as an excellent method of eliminating or reducing the amount of hazardous wastes and other pollutants generated by industry. In fact, the 3P program is referenced in the 1982 annual report of the President's Council on Environmental Quality.

In the state legislative area, 3M strongly supported and lobbied for enactment of the Minnesota Waste Management Act of 1980. Among other things, this Act set up a statewide public participation process for determining the location of a land disposal site for hazardous wastes; it is one of the most comprehensive public participation programs in any state for any reason. 3M also strongly supported and lobbied for the waste site cleanup and matching fund provisions of the Minnesota Environmental Response and Liability Act of 1982 (MERLA).

The record will show that 3M has taken a strong public stand in support of federal and state regulatory efforts to clean up existing waste sites. Industry must continue to bear its part of this effort if the task is to be successful. Similarly, however, there must be a recognition by governmental leaders and the general public that the problem being addressed is societal in nature and cannot fairly be thrust only upon industry, much less a specific segment of industry.

It is this aspect of addressing hazardous waste problems that is one of the most troublesome to 3M. While there may be some short-term political expediency in pointing to industry as the scapegoat to which is directed public hazardous waste concerns, such a policy serves only to create adversarial barriers rather than foster coordinated commitment of the public and private sectors that is necessary to fully address and resolve hazardous waste problems.

It is in this context that 3M has found it necessary to take a public stand against ill-conceived measures that conveniently, but erroneously, focus liability upon industry for society's waste problems. An outstanding example of such a measure is the Minnesota Environmental Response and Liability Act (MERLA) as it applies to personal injury and economic loss liabilities and upon which the Subcommittee has previously received testimony. Although it serves no purpose here to debate the content of this prior testimony, it is important to note that the rather extraordinary provisions of MERLA - provisions that ignore traditional principles of fundamental fairness, if not due process, in order to ensure industry vulnerability to litigation - were not predicated on a demonstrated need for such provisions. Rather, they were promulgated upon an unfortunate mixture of political expediency, anti-business sentiment and the interests of those who stand to gain in litigation representing claimants.

Consequently, there was no desire to address the very real issue of need for such extraordinary measures. But major legislation must be based upon demonstrable facts, not anecdotal scenarios that are neither real world nor demonstrable.

Clearly, this principle should apply to the Subcommittee's consideration of victim compensation legislation. Most certainly, 3M gives support to a program that compensates actual victims where the victims are otherwise without relief. But such legislation should not become reality until there is a comprehensive and factually based demonstration that there are significant health problems from hazardous wastes that current laws and procedures do not address. It simply is not sufficient to rely upon a general public or political perception that there are significant human health problems allegedly caused by exposure to hazardous wastes and that the present legal system does not adequately provide redress for such problems.

At such time as victim compensation legislation is justified in the above-referenced manner, 3M urges that it contain the following provisions:

1. That claimants be required to choose between the administrative remedy of a victim compensation scheme and a tort claim. Compensation under victim compensation legislation must be an exclusive remedy.

2. A pre-emption of other laws that will allow for a consistent and equitable national program for all claimants no matter where situated.

3. A fund whose size is predicated on a demonstrable scope of the problem.

4. A fund that is financed in a manner that correctly recognizes the problem as societal in nature and thus embraces a cost sharing by the public and private sectors with the private sector share being derived from all hazardous waste generators in a manner that reflects not only volume but also degree of toxicity and manner of disposal.

5. Application of the legislation should be solely for disposal site exposures and not occupational exposures.

6. Standardize the statute of limitation period applicable to seeking relief under the legislation. Whatever the period adopted, it should run from the date of discovery of the injury.

At 3M we are mindful of the great difficulty facing the Subcommittee in coming to grips with the victim compensation issue. Of necessity I have here attempted to offer our general comments on the issue. As your consideration progresses, we stand ready to assist you in any manner that may be appropriate.

Thank you again for your patience and the opportunity to present our views on this most important matter. May you have a prosperous New Year.

Sincerely,

c: Sante J. Esposito
